The mass-spectrum of argon shows an exceedingly bright line at 40, with second-order line at 20, and third-order line at $13\frac{1}{3}$. The last is particularly well placed between known reference lines, and its measurement showed that the triply charged atom causing it had a mass 40·00 very

exactly. Now the accepted atomic weight of argon is less than 40, so the presence of a lighter isotope was suggested. This was found at 36, and has now been fully substantiated; its presence to the extent of about 3 per cent. is sufficient to account for the mean atomic weight obtained by density determinations.

The elements hydrogen and helium presented peculiar difficulties, as their lines were too far removed from the reference lines for direct comparison. By means of a special "bracketing" method, moderately accurate values were obtained. Helium appears to be exactly 4 on the oxygen scale, but hydrogen is definitely greater than unity. The value obtained agrees very well with that already arrived at by chemical methods—namely, 1·008. At the same time, measurements of the 3 line, first observed by Sir J. J. Thomson, were made which came out at 3·024, satisfactorily proving it to be due to triatomic hydrogen.

Krypton and xenon gave surprisingly complex results, the former consisting of six isotopes 78, 80, 82, 83, 84, 86. The weights of these could be determined with great accuracy by means of the excellent second- and third-order lines they gave. The first experiments with xenon led to the observation of five isotopes, the provisional values of which were given as one unit too low. Owing to the kindness of Prof. Travers and Dr. Masson, I have recently been enabled to repeat the analysis with gas much richer in xenon. With this the second-order lines could be observed and measured. The five principal isotopes of xenon are 129, 131, 132, 134, 136; there is apparently a faint sixth component at 128, and a doubtful seventh at 130.

Experiments with boron fluoride indicated that boron has at least two isotopes, 10 and 11, and that fluorine is a simple element of atomic weight 19.

Silicon is another unmistakably complex element having two isotopes, 28 and 29, with a possible additional one, 30.

Bromine was of great interest. As it has an atomic weight almost exactly 80, it might reasonably be expected to be simple and an isobare of one of the kryptons; actually it consists of equal parts of 79 and 81.

Sulphur, phosphorus, and arsenic are all apparently simple elements. Mercury is certainly complex, though its closer components cannot be resolved with the present apparatus. Its very characteristic groups are seen as high as the fifth order, and appear on nearly all the spectra taken. The group consists of a continuous succession of lines forming a band 197 to 200, a strong line at 202, and a weak one at 204. Recently at Copenhagen Brönsted and Hevesy have succeeded in partially separating the isotopes of mercury by a fractional distillation at extremely low pressure. They give as their figures for the densities compared with normal mercury as unity:—

Condensed mercury	0·999980
Residual mercury	1·000031

The probable error claimed is less than one part in a million.

Selenium, tellurium, antimony, and tin have all been used in the discharge tube, with no results of any value. This is unfortunate, for the atomic weight of selenium, 79·2, suggests that one of its isotopes must be an isobare of bromine or krypton; also the relation between tellurium and iodine is of great interest.

Iodine, fortunately, gave a very definite result. It is a simple element of atomic weight 127. This is rather surprising, for all the theoretical papers on the isotopic constitution of elements have predicted a complex iodine. Prophecy in physics becomes a difficult trade when experimental results produce these surprises, and apparently the only really trustworthy prediction is that there are plenty more in store for us.

The following is a list of elements and isotopes determined to date:—

Table of Elements and Isotopes.

Element	Atomic number	Atomic weight	Minimum number of isotopes	Masses of isotopes in order of their intensity
H	1	1·008	1	1·008
He	2	3·99	1	4
B	5	10·90	2	11, 10
C	6	12·00	1	12
N	7	14·01	1	14
O	8	16·00	1	16
F	9	19·00	1	19
Ne	10	20·20	2	20, 22, (21)
Si	14	28·30	2	28, 29, (30)
P	15	31·04	1	31
S	16	32·06	1	32
Cl	17	35·46	2	35, 37, (39)
A	18	39·88	2	40, 36
As	33	74·96	1	75
Br	35	79·92	2	79, 81
Kr	36	82·92	6	84, 86, 82, 83, 80, 78
I	53	126·92	1	127
X	54	130·32	5, (7)	129, 132, 131, 134, 136, (128, 130?)
Hg	80	200·60	(6)	(197–200), 202, 204

(Numbers in brackets are provisional only.)

By far the most important result of these measurements is that, with the exception of hydrogen, the weights of the atoms of all the elements measured, and, therefore, almost certainly of all elements, are whole numbers to the accuracy of experiment—namely, about one part in a thousand. Of course, the error expressed in fractions of a unit increases with the weight measured, but with the lighter elements the divergence from the whole-number rule is extremely small.

This enables the most sweeping simplifications to be made in our ideas of mass. The original hypothesis of Prout, put forward in 1815, that all atoms were themselves built of atoms of protyle, a hypothetical element which he tried to identify with hydrogen, is now re-established, with the modification that the primordial atoms are of two kinds—atoms of positive and negative electricity.

Although the latter unit has long been known

to us as an "electron," its mate, which appears to be the real unit of mass, has only recently been given the name of "proton."

The Rutherford atom, whether we take Bohr's or Langmuir's development of it, consists essentially of a positively charged central nucleus around which are set planetary electrons at distances which are great compared with the dimensions of the nucleus itself. As has been stated, the chemical properties of an element depend solely on its atomic number, which is the charge on its nucleus expressed in terms of the unit charge *e*. A neutral atom of an element of atomic number N has a nucleus consisting of K+N protons and K electrons, and around this nucleus are set N electrons. The weight of an electron on the scale we are using is 0·0005, so that it may be neglected. The weight of this atom will, therefore, be K+N, so that if no restrictions are placed on the value of K any number of isotopes is possible.

The first restriction is that, excepting in the case of hydrogen, K can never be less than N, for the atomic weight of an element is always found to be equal to, or greater than, twice its atomic number. The upper values of K also seem to be limited, for, so far, no two isotopes of the same element have been found differing by more than 10 per cent. of its mean atomic weight; the greatest numerical difference is eight units in the case of krypton. The actual occurrence of isotopes does not seem to follow any law at present obvious, though their number is probably limited by some condition of stability.

Protons and electrons may therefore be regarded as the bricks out of which atoms have been constructed. An atom of atomic weight m is turned into one of atomic weight $m+1$ by the addition of a proton *plus* an electron. If both enter the nucleus, the new element will be an isotope of the old one, for the nuclear charge has not been altered. On the other hand, if the proton alone enters the nucleus, and the electron remains outside, an element of next higher atomic number will be formed. If both these new configurations are possible, they will represent elements of the same atomic weight, but with different chemical properties. Such elements are called "isobares," and are actually known among the radio-active elements.

The case of the element hydrogen is unique, for its atom appears to consist of a single proton as nucleus with one planetary electron. It is the only atom in which the nucleus is not composed of a number of protons and electrons packed exceedingly close together. Theory indicates that when such close packing takes place the effective mass will be reduced, so that when four protons are packed together with two electrons to form the helium nucleus this will have a weight rather less than four times that of the hydrogen nucleus, which is actually the case.

It is not to be supposed that the whole-number rule is of exact mathematical accuracy, for the unit of the oxygen scale is a "packed" proton+an electron, and its value will certainly alter slightly with the degree of packing. On this account it is of the greatest importance to push the accuracy of methods of atomic weighing as far as possible, for variations from the whole-number rule, if they could be determined with precision, would give us some hope of laying bare that innermost of secrets, the actual configuration of the charges in the nucleus.

The results I have described lie on the borderline of physics and chemistry, and although as a chemist I view with some dismay the possibility of eighteen different mercuric chlorides, as a physicist it is a great relief to find that Nature employs, at least approximately, standard bricks in her operations of element-building.

Natural Camouflage.[1]

THE fine volume under notice is a new edition of the beautifully illustrated work which, originally appearing in 1909, first brought in a connected form before the public the many classical principles of concealing-coloration established by the genius of the American artist-naturalist Abbott H. Thayer. Important discoveries such as these, especially when the enthusiasm of their originator could recognise well-nigh no limits to their application, were bound to bring sharp differences of opinion. In America we have seen the rise of two rival camps, one, headed by the late Theodore Roosevelt, opposing the whole of Thayer's conclusions, the other accepting the whole and even interpreting the advertisement of Warning Colours and their simulation in Mimicry as examples of the working, in one form or another, of concealing-coloration.

In England, where, as the result of the writings of Wallace and Bates, and still earlier of Erasmus Darwin, the subject as a whole is older, an intermediate position has been taken. Here, naturalists recognise to the full the enduring value and fundamental importance of Thayer's discoveries, although believing that they do not offer a complete interpretation of animal colouring as a whole; and, in the beautiful frontispiece of the book, representing a peacock in the woods with its blue neck against the sky and posed so as to illustrate the conclusion that its pattern is "a marvellous combination of 'obliterative' designs, in forest-colors and patterns," in this and the flamingoes, and spoonbills with "the skies they picture" (plates viii–x), English naturalists

[1] "Concealing-Coloration in the Animal Kingdom. An Exposition of the Laws of Disguise through Colour and Pattern: Being a Summary of Abbott H. Thayer's Disclosures." By Gerald H. Thayer. With an Introductory Essay by A. H. Thayer. New Edition with a New Preface. Illustrated by Abbott H. Thayer and Others, and with Photographs. Pp. xix+260+xvi plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd., 1918.) 25s. net.

believe that they witness the attempt to carry a theory too far, and a tendency to be blinded, by the dazzling brilliancy of one set of interpretations, to the value and importance, and even the existence, of others.

The author's conclusion that all pattern is obliterative does not conflict with the theory of Warning Colours if we bear in mind that obliteration is dependent on distance. This is well shown in Fig. 1, where, as the author states, at the right distance or in a sufficiently reduced light, the brightly patterned butterfly disappears before the three monochrome ones, even the dimmest. We see here the effacing effect of "contrasted juxtaposed color-notes," and are led to understand the inconspicuousness of the zebra as described long ago by Sir Francis Galton, and to conclude that it is this rather than "background-matching," as maintained on pp. 135–36, which is the bionomic meaning of its remarkable pattern. But, returning to the butterfly diagrams, it is obvious that anywhere near the striking distance of an enemy the contrasted colour scheme is far more conspicuous than the other three, and this is all that the theory of Warning Colours requires. That it should be obliterated at a greater distance is all to the good, for, as the present writer has maintained, "all animals with warning colours have enemies, all are liable to special attacks, in times of exceptional hunger, by enemies which would at other times neglect them. . . . Provided such forms are easily seen and avoided by enemies which respect their special modes of defence, it is clearly an advantage to be as far as possible concealed from those which do not respect them" (Trans. Ent. Soc., 1903, p. 573).

FIG. 1.—At a distance of seven or eight yards in bright light or at a shorter distance with less illumination, the brightly patterned butterfly disappears before the three butterflies of monochrome tint. From "Concealing-Coloration in the Animal Kingdom."

The author's interpretation of the black-and-white pattern of the skunk will be sufficiently clear when Figs. 2 and 3 are compared, Fig. 2 being the "mouse's or cricket's view" with the sky let down, as it were, into the pattern, and leaving a black shape unrecognisable as an animal, while Fig. 3 shows the "sky 'background' cut off by dark, making his white conspicuous." To this interpretation it may be objected that it is very doubtful how far a nocturnal animal like the skunk requires to be hidden from its prey, but there is no doubt that it is advantageous for it to be concealed from enemies which mean to attack, and these, so far as I know, are only predaceous birds which would see it from above against the ground. From these the obliterative effect at a great distance of the skunk's contrasted black and white may well be a protection, but to all large ground animals likely to attack it, it would be extremely conspicuous. Furthermore, the slow and deliberate movements of the skunk and the flapping or floating flight of conspicuous butterflies must be remembered in association with their display and the special protection of which it is an advertisement.

FIG. 2.—Mouse's or cricket's view of the common skunk; photographed outdoors from a stuffed skin. From "Concealing-Coloration in the Animal Kingdom."

Although I am unable to agree with these and some other conclusions of the authors, and have been obliged to devote so much of the available space to criticism, I should wish again to em-

phasise the far-reaching importance of the principles which they have clearly explained and beautifully illustrated. It is to be hoped that the volume will be widely and carefully read. Considering the scale and style of the work, with its

FIG. 3.—Common skunk as in Fig. 2, but with sky "background" cut off by dark, making his white conspicuous; photographed outdoors from a stuffed skin. From "Concealing-Coloration in the Animal Kingdom."

sixteen coloured plates and 140 black-and-white figures, the price is very moderate.

The appearance of this new edition is, as is explained by Gerald H. Thayer in his preface, related to the great part which its principles have played in the war. That they should have been collectively named "camouflage" is a curious instance of word-history. "Camouflage" is not to be found in Murray's Oxford Dictionary, but "camouflet" is there, with this meaning: "a mine containing a small charge of powder, placed in a wall of earth between the galleries of besieged and besieger, so as, in exploding, to bury, suffocate, or cut off the retreat of the miner on the opposite side; a 'stifler.'" *"Camouflet or stifler"* is quoted from the "Penny Cyclopædia" of 1836. Then, when smoke came to be employed above ground it kept the same name; and, as its chief use was to act as a concealing screen or curtain, "camouflage" became, in the Great War, transferred from the cause to the effect, and extended to concealment, however attained.

G. H. Thayer states that it has recently come to light that, in Germany, the original edition was "searched through with most diligent care for information which could be put to military or naval use." Here in England its principles were applied long before the war, for many years ago the great guns in our coast forts were painted white beneath to neutralise their shadows, and coloured above with an obliterative pattern. But while all this was done for the guns our men were sent to the war with a cap that seemed specially designed, by its reversal of principles explained in this volume, to render the head conspicuous to an enemy.

E. B. P.

Obituary.

PROF. W. R. BROOKS.

PROF. W. R. BROOKS was one of the most successful of all modern comet-hunters. He nearly equalled the wonderful success of Pons, who found twenty-eight comets in the first twenty-five years of last century. Prof. Brooks's total was twenty-seven comets, but in regard to several of these he was anticipated.

Prof. Brooks was born at Maidstone, Kent, on June 11, 1844, and with his parents migrated to the United States in 1857. He was educated in various public and private schools in England and America. He was awarded the Hon. A.M. degree by Hobart College in 1891, and the Sc.D. by Hamilton College in 1898. He was director of Redhouse Observatory, Phelps, New York, from 1872 to 1888, and was appointed to the Smith Observatory in the latter year; finally he became in 1900 professional astronomer at Hobart College Observatory.

As a discoverer of comets Prof. Brooks was rivalled only by Prof. E. E. Barnard during the years from 1881 to 1911. Some of the comets detected by him during his unwearying sweeps of the heavens were of considerable importance. Thus he was the first to find, in 1883, Pons's periodical comet of 1812, and in 1886 he picked up the expected comet of Olbers, last seen in 1815; he also discovered comets of short periods belonging to the Jovian family in 1886 and 1889. The latter broke up into several fragments and proved quite a notable object.

Like Messier, Pons, Tempel, Barnard, Perrine, and others, Prof. Brooks displayed special ability in this field of observation, and though he engaged in other departments of practical astronomy, it was in exploring the sky for comets that he met with his greatest successes. His results afford another instance of the fact that natural ability combined with enthusiasm, opportunity, and well-directed effort usually bring ample reward.

Prof. Brooks received ten gold prizes from Mr. Warner, and nine comet medals from the Astronomical Society of the Pacific; he also received the Lalande medal from the Paris Academy of Sciences, and a number of other special distinctions. He was elected a fellow of the Royal Astronomical Society on January 13, 1888. His discoveries ranged over the thirty years from 1881 to 1911, but it was during the first twenty years of this period that his principal work was done.

There was nothing in his early life or associations to lead Prof. Brooks to the pursuit of astronomy except his inclination. His initial success in making a reflecting telescope and in finding new comets enabled him to relinquish his daily avocation and to devote the greater part of his life to the study of the heavens. He died on May 3 in his seventy-seventh year.

W. F. DENNING.

THE death occurred in January this year, at seventy-five years of age, of DR. JULES HARMAND, who was well known for his extensive explorations in French Indo-China. In 1873 Dr. Harmand took part in the investigations of the ruins of Angkor, in Cambodia. His explorations in subsequent years embraced the basin of the Tonle Sap and the lake of that name, as well as the country between there and Bassac, on the Mekong. In 1877 Dr. Harmand explored the Boloveu plateau in Laos, and succeeded in crossing the mountainous country to Hué, in Annam. These explorations shed much light on the interior of Indo-China, and gained for Dr. Harmand in 1878 the gold medal of the Paris Geographical Society. Later he entered the diplomatic service and was for many years French ambassador at Tokio. Dr. Harmand was the author of "Domination et Colonisation," published in 1910, and he prepared a French edition of Sir John Strachey's "India" in 1892.

WE learn with regret from *Science* of April 22 that the death occurred on April 14 of DR. HENRY PLATT CUSHING, who was for twenty-six years professor of geology in Western Reserve University, Cleveland, Ohio, and for about the same time geologist in the Adirondack region for the Geological Survey of New York.

Notes.

"CULTURED" pearls, recently introduced by a Japanese firm, appear to have caused some alarm in the gem trade. It has long been known that pearls are the result of local irritation in the pearl-oyster or pearl-mussel, caused by the introduction of some foreign matter—usually the larva of a parasitic organism which spends another part of its life-cycle in an animal that feeds on the mollusc. The mollusc retaliates by coating the unbidden guest with a smooth layer of nacre (identical with the mother-of-pearl layer of its shell, and consisting mainly of the orthorhombic crystalline modification of calcium carbonate corresponding with the mineral aragonite); and the resulting pearl is the elegant tomb of the objectionable parasite. The Chinese have for centuries produced this result artificially by inserting objects between the shell and mantle of the fresh-water mussel, and figures of Buddha on the inner surface of such shells are common. The difficulty hitherto has been to cause the formation of a spherical secretion unattached to the shell of the mollusc. This now appears to have been achieved by Mr. Mikimoto as a result of experiments extending over forty years. It is said that fragments of mother-of-pearl are inserted in the tissues of the molluscs, which are then returned to the sea for a period of several years. Another obvious method would be to infect the oyster-bed with the appropriate parasite. But, whether the foreign matter is introduced accidentally or intentionally, the result produced by the oyster must be the same. The qualification "artificial" would here apply rather to the pretence that the products are essentially different. Attempts on the part of the trade to discredit what is apparently an interesting scientific discovery are clearly made only with the view of keeping up inflated prices. The same selfish fight was made some years ago against the artificially formed rubies and sapphires (miscalled "synthetic," "reconstructed," and even "imitation"), which can be produced much more economically than the naturally formed stones. Strawberries raised in pots under glass are sold without question as strawberries—but wisely at a higher price. Pearls are high in price because of their rarity, but if they were plentiful and the more brightly coloured mother-of-pearl were rare the cry would be very different.

THE Kelvin gold medal for engineering was founded in 1914, principally by British and American engineers, to commemorate the achievements of Lord Kelvin in those branches of science which apply specially to engineering. The award is made by a committee of the presidents of the representative British engineering institutions, and recommendations are received and considered from similar bodies in all parts of the world. The first recipient was Dr. William Cawthorne Unwin, and the presentation was made by Mr. A. J. Balfour in the hall of the Institution of Civil Engineers on Wednesday, May 4. In the course of his address Mr. Balfour said that Lord Kelvin combined in a manner which had scarcely been equalled before, except perhaps by Archimedes, the power of theorising on the darkest and most obscure secrets of Nature, and at the same time of carrying out efficiently and practically some engineering feat. It was therefore fitting that we should remember Kelvin as one of the leaders in the movement which compelled all modern engineers worthy of the name to be not only men of practice, but also of theory. Dr. Unwin's name was honoured wherever engineering was studied in English-speaking lands, and he had imprinted his own seal upon the whole course of study which young engineers had now to pursue. In his reply Dr. Unwin congratulated the young engineers of to-day upon their advantages in the possession of well-organised colleges and on the recognition by all universities, even Oxford and Cambridge, of a faculty of engineering.

WE are very glad that a reasonable agreement has been arrived at between supporters and opponents of the Plumage (Prohibition) Bill, with the result that the Bill passed through Standing Committee D of the House of Commons on May 10. It has often been suggested that an advisory committee should be set up to prepare a schedule of birds the plumage of which might be imported, but this has been objected to by promoters of prohibitive measures. The agreement now arrived at includes the following terms:—

(1) The Act to come into operation nine, instead of six, months after the passing thereof. (2) Within four months after the passing of the Act the Board of Trade shall appoint a joint Advisory Committee consisting of an independent chairman, two expert ornithologists, three representatives of the feather trade, and four other independent members. The function of this Committee will be to advise the Board of Trade as to additions to and removals from the existing schedule (ostrich and eider-duck) of birds the plumage of which may be imported. By the adoption of these clauses the Bill will in all probability be placed on the Statute Book during the present session of Parliament.

An announcement in the *Times* of May 9 states that Sir Hercules Read, Keeper of the Department of British and Medieval Antiquities and Ethnography of the British Museum, will retire in July next on completion of forty years' service. Sir Hercules Read joined the museum staff in 1880 under Sir Wollaston Franks, with whom he had worked for six years previously, and whom he succeeded in 1896. Under him the department has developed greatly, particularly in connection with prehistoric and medieval antiquities. By his influence among wealthy connoisseurs, of whom he numbered a great many among his friends, he was able to secure for his department and the nation a large number of valuable specimens of artistic or scientific importance which otherwise might have been lost to us. Mr. J. Pierpont Morgan was largely guided by him in his generous gifts to public collections, and it was at his instigation that the famous Greenwell collection of Bronze-age antiquities was secured and presented by Mr. Morgan to the museum. Sir Hercules Read's connection with the British Museum will not be severed by his retirement. As president of the Society of Antiquaries he will continue to act as a Trustee *ex officio*.

In presiding at a dinner given by the council of the Iron and Steel Institute to the president, Dr. J. E. Stead, last week, Sir Robert Hadfield spoke at some length on the industrial crisis in this country. He took the view that the present Labour disturbance was unreasonable, since it had been admitted by some of the miners' leaders that its object was political. He stated that no one wished to see reductions in the income of the wage-earners less than he did, but that the existing fictitious state of affairs, both financial and industrial, made it impossible for us to get on a sound footing until some re-adjustment, in which all were concerned, took place. Sir Robert Hadfield went on to urge the need for a greatly increased output per worker, stating that it was only in this way that industry could be restored to an economic basis. In the latter part of his speech he dealt with technical problems, alluding particularly to corrosion, affirming that his study of this question, in so far as it related to iron and steel, had convinced him that the annual wastage was from 1·5 to 2 per cent.

At a general meeting of the members of the Royal Institution held on May 9 Sir J. J. Thomson was elected honorary professor of natural philosophy and Sir Ernest Rutherford professor of natural philosophy.

At the meeting of the Royal Society held on May 5 the following were elected foreign members:—Prof. Albert Calmette, Dr. Henri Deslandres, Prof. Albert Einstein, Prof. Albin Haller, Prof. E. B. Wilson, and Prof. P. Zeeman.

At the annual meeting of the British International Association of Journalists, held on April 22, Mr. Leon Gaster, the hon. secretary of the Illuminating Engineering Society and editor of the *Illuminating Engineer*, was unanimously elected the honorary general secretary of this association.

By invitation of the chairman of the Lawes Agricultural Trust Committee, Lord Bledisloe, and the director, Dr. E. J. Russell, the House of Commons Agricultural Committee and certain members of the House of Lords will visit the Rothamsted Experimental Station, Harpenden, to-morrow, May 13, to inspect the experimental farm and the laboratories.

The last ordinary scientific meeting of the Chemical Society this session will be held at the Institution of Mechanical Engineers, Storey's Gate, on June 16 at 8 p.m., when Prof. Benjamin Moore will deliver a lecture entitled "The Natural Photo-synthetic Processes on Land and in Sea and Air, and their Relation to the Origin and Preservation of Life upon the Earth."

The Empire Cotton-Growing Committee and the British Cotton Industry Research Association propose to award in July next about twelve studentships, each of the annual value of 200*l*., for the additional training of university graduates in scientific research bearing on plant genetics and physiology, entomology, physics, etc., or in special subjects relating to administration and inspection in tropical agriculture. Forms of application and further particulars of the studentships are to be obtained from the secretary of the Joint Standing Committee, c/o the Shirley Institute, Didsbury, Manchester, not later than July 18.

The officers and council of the Manchester Literary and Philosophical Society for the new session 1921–22 were elected on April 26 as follows:—*President:* Mr. T. A. Coward. *Vice-Presidents:* Mr. R. L. Taylor, Mr. William Thomson, Sir Henry A. Miers, and Mr. W. Henry Todd. *Hon. Secretaries:* Dr. H. F. Coward and Prof. T. H. Pear. *Hon. Treasurer:* Mr. R. H. Clayton. *Hon. Librarians:* Mr. C. L. Barnes and Dr. Wilfrid Robinson. *Hon. Curator:* Prof. W. W. Haldane Gee. *Council:* Prof. Arthur Lapworth, Mr. C. E. Stromeyer, Dr. W. M. Tattersall, Mr. Leonard E. Vlies, Mr. F. W. Atack, Prof. F. E. Weiss, Mr. Francis Jones, Miss Laura Start, and Prof. Sydney Chapman. The Chemical Section on May 6 elected the following officers:—*Chairman:* Mr. Leonard E. Vlies. *Vice-Chairman:* Mr. J. H. Lester. *Hon. Secretary:* Mr. David Cardwell.

THE London summer meeting of the Institution of Mechanical Engineers, which will be held on June 30 and July 1, will be devoted to subjects connected with the better utilisation of fuels. A novel feature of the meeting will be an exhibition of appliances connected with boiler-room economy and with the efficient use of steam- and internal-combustion engines. The exhibits will include feed-water heaters, combustion recorders, super-heaters, liquid fuel and powdered fuel burners, steam- and gas-engine indicators, etc. The institution desires that all who have exhibits to offer will communicate with the secretary at Storey's Gate, St. James's Park, S.W.1, as soon as possible. Apparatus and models are preferred, but drawings will be accepted and suitably displayed.

ARRANGEMENTS have been made by the Institution of Civil Engineers to continue this year the series of conferences which were interrupted by the rebuilding of the institution premises and the war. A conference will be held on Wednesday, Thursday, and Friday, June 29 and 30 and July 1, the mornings being given to discussions upon selected topics, and the afternoons to visits to engineering works. For the purpose of the meetings the conference will be divided into seven sections: (i) Railways, Roads, Bridges, and Tunnels; (ii) Harbours, Docks, Rivers, and Canals; (iii) Machinery; (iv) Mining and Metallurgical Processes; (v) Shipbuilding; (vi) Waterworks, Sewerage, and Gasworks; (vii) Electricity Works and Power Transmission. The twenty-seventh James Forrest lecture will be delivered by Sir George T. Beilby on the afternoon or evening of Tuesday, June 28.

"THE Physiology of Pain" is the subject of a paper in *Medical Science: Abstracts and Reviews* for April (vol. iv., No. 1). The reviewer concludes: "It is, at any rate, tempting to regard sensibility to pain as the survival in us of the primordial mode of sensation. Its urgency and tendency to evoke immediate motor response is the reproduction of the normal experience of the lower invertebrates. From it the discriminative forms of sensibility have been differentiated by the progressive increase of insulation. If we view pain as an exaggerated response by a physiologically irritated nerve, it is possible to get some conception why pain is the commonest of symptoms and why it is so apt to become inveterate. Pain is, as it were, physiologically only just not present in us all, and what appears to be a very slight disturbance pathologically may prove an effective and incurable excitant of it."

DR. L. O. HOWARD's annual report of the Entomologist to the U.S. Department of Agriculture for the year ending June 30, 1920, is a record of a vast series of researches carried out for the benefit of the State. The European corn-borer is causing anxiety on account of the increasing area of country that is suffering from its ravages. With an appropriation of 400,000 dollars an energetic campaign is being conducted, and particular attention is being devoted to the natural enemies of the pest. A trained observer has been established in the south of France to study its native parasites, and Dr. Howard personally visited with the same object regions of Belgium, France, and Italy in which the corn-borer occurs. In connection with insecticides for orchard spraying, much experimental work has been accomplished with contact insecticides in an effort to find something to replace nicotine or tobacco extract. Special attention has been devoted to organic contact sprays, and a compound has been discovered of the pyridine series which offers hopes of success. As in previous years, work on the Gipsy and Brown Tail moths occupies a prominent place. During the spring of 1919 favourable climatic conditions for hatching out the eggs resulted in an unusual spread of the former insect in the caterpillar stage, and an increase in area of 4569 square miles is now stated to be infested. On the other hand, the area affected by the Brown Tail moth has been materially reduced, and 10,677 square miles have been released from the quarantine.

MR. H. G. MAY has published (Proc. U.S. Nat. Mus., vol. lviii., pp. 577–88, 5 plates, 1920) useful notes on the nematode genus Nematodirus, which occurs in the small intestine of sheep, goats, cattle, deer, camels, and certain rodents. In addition to abundant material collected in the United States, the author has received material from France and Switzerland, and has been able to study some eight hundred male specimens for their spicules. He finds in this collection four species which have not previously been described. He gives a key to, and short descriptions of, the nine species of the genus, and figures the more important systematic characters, especially the bursæ and spicules of the males.

AT a meeting of the Biological Society of Washington (Journal of the Washington Academy of Sciences, vol. x., No. 20, p. 580, December, 1920) Mr. T. E. Snyder directed attention to the extensive and serious injury caused to the lead sheathing of aerial telephone cables in California by the beetle *Scobicia declivis*, which normally breeds in recently felled wood piled for later use as fuel. In summer the beetle attacks the cable where it lies in contact with the metal suspension ring, which affords it leverage for boring. The hole allows moisture to penetrate the insulation, and numerous widely separated short-circuits are produced when rain falls in the autumn. A high percentage of "wire trouble" is caused by this beetle. No remedy has yet been found; chemical repellents, various types of suspension rings, and hard tin and antimony alloys have proved ineffective.

IN the Report for 1919 of the Botanical Society and Exchange Club of the British Isles the secretary, Dr. G. C. Druce, provides a supplement entitled "The Extinct and Dubious Plants of Britain." Notwithstanding the great changes which have occurred in Britain during the period since 1597, only about half a dozen native species of flowering plants have ceased to exist, mainly as the result of drainage operations. The most notable are a Vetch (*Vicia laevigata*), which formerly occurred near the shore at Weymouth and Portland, but does not seem to have been found for nearly a hundred years, and two species of Senecio,

formerly plentiful in the Fens, but destroyed by drainage operations. During the same period our flora has been augmented by a number of emigrants from other countries which have become more or less completely established. The dubious plants of Britain—that is to say, plants which have been reported as British—make a very long list. Some are mere casuals, many have been wrongly identified, and some, it is to be feared, were wilful impositions. The probability is that the majority were really erroneous, but Dr. Druce suggests that the publication of these records in an easily consultable form may, by directing attention to them, lead to one or two being re-discovered.

MR. N. H. DARTON (U.S. Geol. Surv., Bull. 701, 1920) has brought together "all available published data bearing on the rate of increase of underground temperature with increasing depth in the United States," including numerous original observations by the author and his colleagues. Some of the very deep wells drilled for oil give average rises of temperature of 1° F. for every 70 ft., the rise being near the surface, and in the deepest levels being about 1° F. for every 60 ft. The following records are of special interest:—McDonald, Pa. (6975 ft.), bottom temperature 144·9° F.; the Lake Well, West Virginia (7500 ft.), at bottom 168·6° F.; and the Goff Well in the same State (7386 ft.), temperature at 7310 ft. 158·3° F. The misleading nature of generalised calculations from depths of less than a mile is clearly shown by the fact that the Goff Well gives from 100 ft. to 7310 ft. a rise of 1° F. for every 70·2 ft., and from 4000 ft. to 7250 ft. of 1° F. for every 56·3 ft. The author reminds us that the workings in the Comstock Lode, Nevada, showed 170° F. at 3100 ft., the average increase in the district being 1° F. for 33 ft. The rate here decreases at similar horizons away from the lode, and local volcanic material is inferred.

THE Bureau of Standards at Washington has issued as Scientific Paper No. 406 a valuable review by Dr. Coblentz of the present position of our knowledge of the laws of radiation of a perfectly black body, and the values of the constants which enter into the numerical expression of those laws. He finds that a considerable proportion of the discrepancies between the results of determinations by different observers is due to the neglect of the absorption of the radiation on its passage from the furnace to the measuring instrument, and to its partial reflection at the receiving surface. On making suitable corrections for these losses he finds that the results are brought into close agreement. He gives as the best value of the coefficient of Stefan's law of total radiation $5{\cdot}72 \times 10^{-5}$ ergs per sq. cm. per second per fourth power of the absolute temperature. For the constant C of Planck's radiation formula he gives 14,320 micron degrees, and for the product of the wave-length for maximum radiation into the absolute temperature 2885 micron degrees. The mean value of Planck's constant h by radiation and other methods he gives as $6{\cdot}55 \times 10^{-27}$ erg-seconds.

IN the April number of the Journal of the Franklin Institute, Messrs. Loyd A. Jones and C. E. Fawkes give the results of their investigations into the action of photographic reducers on the images produced on development printing papers. The course of the change is traced in each case by measuring the density of the image after subjecting it to the reagent employed for various times. It is possible to reduce so that the contrast is either unchanged, diminished, or increased. The chief point of novelty demonstrated is the action of ammonium persulphate, which in the presence of a little sodium chloride gives a nearly proportional decrease of density. But if the persulphate is dissolved alone in distilled water there is a certain critical point on the density curve, on the thinner side of which there is very little change, while there is very vigorous action on the denser side. Even in so short a time as three minutes, that part of the curve that lies above the point is reversed in its curvature, and parts of it become less dense than the critical point itself. The authors give the formulæ of the solutions that they used.

IN his presidential address delivered recently to the Institution of Mining and Metallurgy Mr. F. W. Harbord dealt with the chief metallurgical developments which have taken place in this country since 1914. According to him, the only new industries which were established as the result of war requirements were the manufacture of tungsten powder and of ferro-alloys generally. In regard to these products the country is now able not merely to supply its own requirements, but also to compete in the chief markets of the world. The output of carbon steel was increased by more than 2,000,000 tons in 1917 as compared with 1913. More than one-half of this increase was due to "basic" steel. In the years 1916–18 arrangements were made for the erection of 22 blast furnaces and 166 open-hearth steel furnaces with a producing capacity of more than 3,000,000 tons per annum. No branch of metallurgy received a greater stimulus and made greater progress than the art of making and heat-treating special steels, especially those containing nickel, chromium, and vanadium. For many years before the war the zinc industry was in a languishing condition. Here again the productive capacity of the country has been much increased by the erection of new plant and by extensions and improvements to existing plants. The present position of this industry is quite abnormal, but when the relation between cost of production and market price becomes normal Mr. Harbord is of opinion that this country will have two very strong points in its favour, owing to the Government control of Broken Hill ore supplies and the better equipment of the extraction works.

AT the eleventh annual May lecture of the Institute of Metals on May 4 Prof. T. Turner took as his subject "The Casting of Metals," which dates back to early antiquity. The quality of the older material cannot be equalled to-day, although output has been enormously increased and the percentage of "wasters" reduced. Aluminium presents special difficulty on account of its high coefficient of expansion; this leads to fracture during cooling unless proper precautions are taken. Gases in non-ferrous metals are not so important as in steel, and any metal or alloy which does not develop gas by reaction or does not unduly

segregate can be cast in a satisfactory manner provided that a suitable temperature is employed, that the mould is properly designed and made, and that the metal is skimmed and poured in the right manner. Pure metals or single substances, as a general rule, possess the same density whether slowly or quickly cooled. Those alloys in which there is an interval between the liquidus and solidus solidify over a temperature range, and often expand when slowly cooled, as, for instance, when cast in sand. Extensometer tests by Prof. Turner have shown the nature and extent of such expansions in a number of typical alloys. These results agree with the density determinations, but the extensometer has the advantage of showing the sequence and amount of each volume-change. In practice one of the chief causes of failure is pouring at too high or too low a temperature. Other causes include such troubles as imperfect or badly fixed cores, faults in moulding, cracks, mis-runs or run-outs, and breakage in handling. In foundry work generally the losses from all causes reach about 10 per cent. of the output. Prof. Turner took the view that casting is fundamentally an art, and the part of the man of science will be to introduce new ideas and processes rather than to improve on present technique.

THE Oxford University Press is to publish under the title of "From a Modern University: Some Aims and Aspirations of Science" a volume of occasional addresses by Prof. A. Smithells.

A LENGTHY catalogue (No. 88) of botanical and horticultural works which are for sale by Messrs. Dulau and Co., Ltd., 34 Margaret Street, W.1, has just reached us. It gives particulars of no fewer than 3017 publications, including the library of the late M. Edouard André, of Paris. Many early printed and rare herbals are listed, and practically the whole range of botany and horticulture is represented. The catalogue should be seen by all who wish to augment their libraries in these branches of science.

MESSRS. G. BELL AND SONS are shortly adding a new volume to the advanced section of their mathematical series, namely, "A First Course in Statistics," by D. Caradog Jones. The fundamental importance of the right use of statistics is becoming increasingly evident on all sides of life, social and commercial, political and economic. It is hoped that a study of this book will enable the reader to discriminate between the masses of valuable and worthless figures published, and to use what is of value intelligently.

Our Astronomical Column.

ECLIPSE OF RHEA BY TITAN.—The computing section of the British Astronomical Association, recently formed under the directorship of Mr. L. J. Comrie, undertook an extensive examination of the phenomena of Saturn's ring and satellites about the time when their planes are turned edgewise. In the course of this work the prediction was made that the very rare phenomenon of the eclipse of Rhea by the shadow of Titan would take place on April 8. A number of members of the association, including the president, Major Hepburn, observed the phenomenon, and found a satisfactory accord with the prediction. Rhea faded rapidly at 10h. 22m., and became invisible for 50 minutes; the estimated time of mid-eclipse was 10h. 47·3m. G.M.T.; the corresponding predicted time was 10h. 38m., and predicted duration 44 minutes. Since the relative motion of the satellites was slow the error in their positions is small.

It would be well if the national ephemerides could publish predictions of interesting phenomena of this character, as there is a danger of their escaping notice if left to unofficial agencies. There is probably no other observation of the kind on record in the Saturnian system; even in the Jovian system, where mutual eclipses occur more often, very few have been recorded, obviously because they have never been systematically predicted.

COMETS.—*L'Astronomie* for April contains a rediscussion by Mr. G. Neujmin of the orbit of the comet (1916*a*) discovered by him in 1916. He finds:—

$$T = 1916 \text{ March } 11{\cdot}3239 \text{ G.M.T.}$$
$$\left.\begin{aligned}\omega &= 193^\circ\ 47'\ 33''\\ \Omega &= 327^\circ\ 33'\ 0''\\ i &= 10^\circ\ 37'\ 12''\end{aligned}\right\} 1916{\cdot}0$$
$$\phi = 34^\circ\ 26'\ 33''$$
$$\mu = 655{\cdot}364''$$
Period 5·414 years.

The observations used extended from February 27 to June 5. The comet should be in perihelion again about August 10 of the present year, but so unfavourably placed that it is to be feared that it will escape detection.

Comet Pons-Winnecke has been deviating from the predicted path with unexpected rapidity, and M. Ebell has deduced the following revised orbit from observations on April 12, 16, and 26:—

$$T = 1921 \text{ June } 13{\cdot}08 \qquad i = 18^\circ\ 15{\cdot}0'$$
$$\omega = 171^\circ\ 43{\cdot}7' \qquad \log q = 0{\cdot}0152$$
$$\Omega = 96^\circ\ 38{\cdot}9' \qquad \log a = 0{\cdot}4526$$

The value of $\log a$ is almost certainly much below the truth, but the elements will probably represent the motion for the next few weeks. The ephemeris printed in this column needs to be corrected by -13m., $-1^\circ\ 11'$ on May 14, and -25m., $-1^\circ\ 12'$ on May 20. It will be noticed that the perihelion point is now placed well outside the earth's orbit, which makes the occurrence of a meteor shower somewhat doubtful.

Ephemeris for Greenwich Midnight.

The Stone-axe Factory of Graig-lwyd, Penmaenmawr.

AT a meeting of the Royal Anthropological Institute held on April 19 Mr. S. Hazzledine Warren presented a report on the results of excavations at Graig-lwyd carried out in June, 1920, under a representative committee appointed by the Royal Anthropological Institute. The expenses of the excavation were met by grants from the National Museum of Wales, the Cambrian Archæological Association, and other public and private contributors.

The Neolithic workings follow the chilled margin of the Penmaenmawr intrusive rock for a considerable distance, but the excavation was mainly concentrated upon one important chipping "floor" associated with the site of a large hearth.

The workers made their stone axes either directly from the natural blocks of scree or indirectly by first striking off large flakes. These large primary flakes often weigh from 7 lb. to 14 lb., or even more, and their production in such a tough and intractable material is evidence of remarkable skill. "Core implements" and "flake implements" were made indifferently, according to convenience in working the stone. The stages of manufacture from the natural block to the finished axe may be grouped as (1) preliminary, (2) intermediate, and (3) advanced. The most characteristic forms arrested in the middle stage may be described as "intermediate ovates"; these might well be mistaken for Late Chelles and St. Acheul implements, while many of the smaller specimens in the preliminary stage resemble the earlier Chelles group. Pseudo-Mousterian flakes with faceted platforms, recalling the Levallois technique, were produced in large quantities as a waste product from the flaking of the axes. More than four hundred "ends of celts" (as they are usually called) were found, and thirty-two complete axes have been refitted from these halves broken during manufacture. The industry is essentially similar to that of Grime's Graves and Cissbury.

Four broken polished axes were recovered from the main "floor," and three of these had been rechipped after breakage into makeshift blades. One stone plaque engraved with a series of triangles was also discovered.

In opening a discussion on the report Sir William Boyd Dawkins said that a debt of gratitude was due to Mr. Warren for having brought these facts, the result of much hard work, before the institute. The subject was of the greatest interest and importance to British archæology at the present time. The finds at Graig-lwyd must be grouped with those from Cissbury and Grime's Graves. As a result of a careful comparison with the long series of finds from Cissbury in the Manchester Museum, he had come to the conclusion that every peculiarity in the Graig-lwyd specimens could be paralleled from Cissbury, the one difference being that the Graig-lwyd implements were made of igneous rock, while the Cissbury finds were flint. The Graig-lwyd specimens were consequently larger owing to the difference in material. The shape and the rude character of a specimen did not prove that it was not of Neolithic age. He himself had found at Trenton, New Jersey, side by side with typical Indian stone implements, specimens which in form belong to the Moustier and other European Palæolithic types. The lesson to be learned from this find was that age cannot be estimated from form. As regards the positive evidence for date of these *ateliers*, it was beyond question. At Cissbury Neolithic pottery and the remains of domestic animals had been found. The evidence from Grime's Graves was clear. There the flint from which implements were manufactured was taken from pits and galleries, and was therefore later in date than these, but the workings show that the greater number of these galleries had been excavated with polished stone axes, and therefore the implements of Chellean, Moustier, and other types found on this site were Neolithic. The conclusion to which this evidence pointed was supported by the types in Mr. Warren's find. The examples of specimens broken in course of manufacture in Neolithic times, of which the parts now reassembled by Mr. Warren exhibited differences in patination, were also a proof that patination was no criterion of age. The discovery of this factory had an interesting bearing upon the question of prehistoric trade and communication. Owing to the existence of a felsitic stone implement factory in the Lake District, he had hitherto derived the felsite axes found in the Midlands from this source, but in future the felsite at Graig-lwyd would have to be taken into account.

The implements from the Graig-lwyd excavations, which will be reproduced in illustration of the report when it is printed *in extenso*, were exhibited at the Royal Anthropological Institute on April 20–22. A larger and more representative collection is to be exhibited at the rooms of the Society of Antiquaries, Burlington House, on May 23–25.

Descriptive Botany.

UNDER the title "The Leguminous Plants of Hawaii" (issued by the Experiment Station of the Hawaiian Sugar Planters' Association), Mr. J. F. Rock gives a systematic account of the native, introduced, and naturalised trees, shrubs, vines, and herbs belonging to the family Leguminosæ. Detailed descriptions are given of all the native and established species, with notes on distribution and economic uses; keys to the genera and species are also included. In all, 200 species belonging to 71 genera are described, and there are 93 excellent full-page photographic reproductions of the more important species. The percentage of indigenous species in this family is very small, and of these only six are trees, one is a shrub, and the remainder are, with few exceptions, usually shore-plants or grow near the shore, and are distributed over most of the Pacific Islands. This poor representation of one of the largest families of flowering plants contrasts remarkably with its rich representation in tropical Asia, and is a strong argument against the existence of any previous land connection with the Asiatic continent. The writer regards the Leguminosæ as a strong factor in proving the assumption that the Hawaiian islands are purely oceanic in character; he proposes to discuss thoroughly the origin of the flora in a work on the phytogeography of the islands which he has in preparation.

In "Icones Plantarum Formosanarum," vol. ix.

(Bureau of Forestry, Government of Formosa), Bunzo Hayata continues his descriptive account of the flora of this island. The volume contains studies of genera of a large number of families of flowering plants, and includes descriptions of 139 new species; the arrangement follows the system of Bentham and Hooker's "Genera Plantarum." The descriptions (in Latin) are full and clear, and the volume is remarkably well illustrated with text-figures and plates. Two new genera are established, one, Dolichovigna, a climbing bean near Phaseolus and Vigna; the other, Pseudosmilax, a member of the family Liliaceæ, and intermediate between Smilax and Heterosmilax. Nine genera are also recorded as new to the flora of the island, which so far as is at present known includes 3608 species of flowering plants representing 1185 genera and 169 families.

In the *Journal of Ecology* (vol. viii., No. 1) Miss L. S. Gibbs gives an account of the phytogeography and flora of the mountain-summit plateaux of Tasmania based on her own observations and collections. The vegetation of the island may be divided into three principal plant formations: (1) The austral-montane flora of the mountain-summit plateaux, which represent the remains of the huge lava plateau of which the island formerly consisted. The major and most interesting portion of the endemic flora is entirely limited to these summit plateaux; one of the peculiar features is the almost complete absence of herbaceous plants. (2) The mixed forest of the west coast, not very rich in species and characterised more by denseness of growth than by height. There is a marked endemic element in this flora which probably originated on the higher lands. (3) Eucalyptus formation, occupying the greater part of the island, consisting mainly of secondary open forest, and purely Australian in type. A description is given of the various portions of isolated tableland which form the mountains of the island and at no point exceed 5000 ft., and the writer describes the chief plant-associations, enumerating the plants which she collected in each. On the most exposed and highest levels a mosaic of small moss-like plants is developed, with inconspicuous flowers, forming a hard, even surface. This is succeeded by a mountain shrubbery, the dominant association of the more exposed portions of the plateau summits. Lower come forest-associations in succession, namely, dwarf mountain forest, low mountain forest, and Eucalyptus scrub. In conclusion, the author refers to the marked relation between the mountain flora of North-West New Guinea, the subject of a former paper, and the so-called "Antarctic flora" of the southern hemisphere. Recent work on meteorological conditions provides an explanation of this relation, namely, in the persistent north-west wind of high altitude over the mountains of New Guinea and across the Australian continent. Seeds transported by this agency would be precipitated in southern latitudes, where they remain within the radius of the persistent westerly winds and gales of the Antarctic seas.

A systematic enumeration is given of the species collected on the mountain-summit plateaux and in the mixed forest from September, 1914, to March, 1915.

Origin of Petroleum and Cause of Gas Pressure.[1]

THE important volume referred to below is bountifully illustrated with photographs, sections, and maps, and gives a comprehensive account of some 150 square miles in the midst of the Californian oilfields, a territory which provides nearly half the oil which the State produces, and includes its greatest oilfield. Here, too, is the famous "Lakeview Gusher," which yielded 8,000,000 barrels of oil in eighteen months. The area has been discussed previously both by State and Federal geologists, notably some ten years ago by R. Arnold, H. Johnson, and R. Anderson in Bulletins 406 and 471, but since that time there has been much further development, and many new facts are available.

The work contains a wealth of information which is rendered easily accessible by its systematic arrangement and clear table of contents. The book commences with a brief "Summary of Results," which is followed by an informative bibliography. "Stratigraphy," which occupies 34 pages, is dealt with under the headings of the various formations. Then follow "Structure" (pp. 54–63) and "Petroleum" (pp. 63–87), whilst a detailed description of the "Productive Field" occupies the latter half of the book. In the pocket at the back of the volume is a geologic map of the region and large-scale topographic and structure maps of the oilfield, together with many sections across the productive area.

The main scientific inferences differ little from those set forth in the earlier bulletins. It is made clear that the petroleum was generated within the Tertiary deposits, which are at least 18,000 ft. in thickness, ranging from Eocene to Pliocene. Regarding the origin of the oil, the author's explanation is that previously formulated by Arnold and Anderson; but he does not ascribe the source of the carbon wholly to the diatoms and foraminifera. "The petroleum has originated in the diatomaceous shale formations, chiefly from the alternation of organic matter contained in diatoms and foraminifers, but probably in part *also from the alteration of terrestrial vegetal débris*." Later "the oil has collected in part in sandy beds that are intercalated with the [diatomaceous] shale, but chiefly in the porous beds of younger formations that rest unconformably upon the shale."

With reference to migration and accumulation, the author affirms that much of the oil in the pools "has migrated from the beds beneath the San Joaquin Valley to the foothills and collected in the small anticlines that extend from the hills out into the valley." The reservoirs of oil are now chiefly in the later Tertiary "[Miocene or Pliocene] sandy beds that rest unconformably upon the diatomaceous shale."

Some interesting matters are discussed in connection with the gas pressure and concerning chemical reactions on the petroleum within the oilsands. The pressure in these fields is not proportionate to depth, and usually is considerably in excess of the theoretical "hydrostatic pressure." The author holds that the oil, whilst within the reservoirs, has been affected by chemical reactions with minerals. In particular, oxidation by sulphate-laden waters has produced a marginal ring of heavy tar around the pool where its bottom rests upon the under-water. This tar seals the oil pool within a definite space, and any further quantities of gas generated from the oil can be accommodated only by increase of pressure. Such conditions probably account for the great gusher-wells of this region.

The University of London.

PRESENTATION DAY.

PRESENTATION DAY of the University of London, which was held at the Albert Hall on May 5, was memorable in many ways, but in two especially: by the admission of the Prince of Wales as an honorary graduate and by the large number of successful graduates who were presented to the Vice-Chancellor for their degrees. The honorary degrees of the University are very jealously guarded; until now the names of Kelvin and Lister have been the only additions to those of the King and Queen. The Prince was admitted to the degrees of Master of Commerce and Doctor of Science. The Chancellor, Lord Rosebery, who was prevented by illness from attending, sent a message in which he made a felicitous reference to the "incomparable Prince," who, he said, had merited a travelling fellowship for the services he had performed in the cause of the Empire. The long procession of graduates in their brilliant robes was an impressive sight, and brought home to the vast audience the magnitude and variety of the work of the University.

The Principal Officer of the University (Sir Cooper Perry) read his report for the year 1920–21, which was written in his accustomed distinguished style. The preamble to the effect that if the "normal year" is still in the distant future, the University is struggling through this "difficult period of strain and stress" with unimpaired strength and a quickened insight into the needs of the community, is fully corroborated by some remarkable statistics, particularly the increase in matriculations from 6638 in 1913–14 to 15,539 in 1920–21. The number of candidates for degrees, 1746 (1036 internal and 710 external), is slightly below the pre-war total, but it is noteworthy that the internal candidates considerably exceed the external, though in 1913–14 the two categories were about equal. The number of internal students is now 7870, and candidates for the new Ph.D. degree already amount to 179. Except for the benefaction of the Government—if such it can be called—of the site of $11\frac{1}{2}$ acres in Bloomsbury for new headquarters, upon the question of accepting which the Senate deliberated, as the Principal plaintively remarked, from May to October last year, the University, apart from its colleges, has not benefited greatly during the year from public or private generosity; but the super-benefaction of the Rockefeller Foundation to University College and Hospital for medical education, amounting to 1,250,000*l.* sterling, beats all previous records in this country. The obituary of the year is short, but includes some outstanding names—Dr. Ronald Burrows, Lord Moulton, Lord Cozens-Hardy, Sir John Macdonell, and Sir Felix Semon.

It was originally proposed that, as last year, a graduation dinner should be held at the Guildhall, but in view of the existing situation this was abandoned and a daylight conversazione substituted. The function was very successful. An interesting presentation was made to the Prince by Sir Israel Gollancz on behalf of graduates of the University. This took the form of a beautiful fifteenth-century MS. containing the signature of the Black Prince and a variant of the historic motto "Ich dien" which throws considerable light on its origin. The Prince returned thanks in a happy and characteristic speech, and afterwards received all the newly made graduates and other members of the assembly.

The advanced public lectures in scientific and other subjects arranged under the auspices of the University are extremely interesting to students and workers in the various branches of knowledge with which they deal. They are given for the most part by distinguished men of science and scholars who are not teachers of the University, and are open to the public without fee. Mr. J. H. Jeans, secretary of the Royal Society, is attracting crowded audiences to King's College, where he is delivering a course on cosmogony and stellar evolution. Prof. Cohen, of Utrecht, is announced to give two lectures (in English) at University College on the metastability of matter; Sir Napier Shaw is delivering an historical course on meteorological theory at the Meteorological Office, and Prof. H. E. Armstrong two lectures on enzymes in relation to plant growth at King's College.

There has been recently an exchange of lectures in medical subjects between London and the Dutch universities, which has been a conspicuous success and may well prove to be the beginning of a complete scheme of exchanges. Under the scheme Dr. Hamburger, the distinguished professor of physiology at Groningen, will lecture at the Royal Society of Medicine on permeability in physiology and pathology on June 8. Dr. Kappers, the director of the Central Institute for Brain Research at Amsterdam, is also giving a course of four lectures on the interpretation of the structure of the brain. All these lectures will be delivered in English.

University and Educational Intelligence.

CAMBRIDGE.—A memorial has been presented to the council of the Senate for a syndicate to be appointed to consider possible alterations in the Mathematical and Natural Sciences Triposes with the object of facilitating the acquisition by candidates in one subject of a knowledge of the other.

It is proposed to appoint Prof. H. Lamb, now in residence in Cambridge, to an honorary University lectureship to be called the Rayleigh lectureship in mathematics.

The Humphry Owen Jones lectureship in physical chemistry is to be revived.

Mr. L. A. Pars has been elected to a fellowship at Jesus College.

LONDON.—The following advanced lectures in physiology and medicine are announced:—A course of eight lectures on "Metabolism of Cholesterol and the Sterols," by Mr. J. A. Gardner, at the London (R.F.H.) School of Medicine for Women, at 5 p.m. on Tuesdays, May 17, 24, 31, June 7, 14, 21, 28, and July 5, 1921. A course of eight lectures on "Experimental Studies in Vegetable Physiology and Vegetable Electricity," by Dr. A. D. Waller and Mr. J. C. Waller, in the Physiological Laboratory of the University, South Kensington, S.W.7, at 5.15 p.m. on Wednesdays, May 18, 25, June 1, 8, 15, 22, 29, and July 6. A course of four lectures on "The Interpretation of the Structure of the Brain," by Dr. C. U. Ariens Kappers (director of the Central Institute for Brain Research, Amsterdam), in the Department of Anatomy, University College, at 5 p.m. on May 13, 17, 19, and 20. These courses are addressed to advanced students of the University and to others interested in the subject. Admission is free, without ticket.

The semi-general election of members of the Senate for the period 1921–25 has resulted in the appointment of the following representatives of science:—By Convocation: G. D. Dunkerley, Sir Philip Magnus, Bart., M.P., and Dr. R. M. Walmsley. Faculty of Science: Prof. A. Dendy and Prof. A. N.

Whitehead. Faculty of Engineering: Prof. H. C. H. Carpenter. Faculty of Economics: Prof. Graham Wallas.

Until recently the degrees of Master of Science and Master of Arts were granted to both internal and external students of the University on a thesis embodying the results of research, but, if thought necessary, an examinational test might also be imposed. Last year, however, the Senate resolved that on the external side these degrees should be given in and after 1923, not for research, but on the results of an examination. This was felt in many quarters to be a retrograde step, and at the meeting of Convocation held on May 3 Mr. Plymen moved and Major Church seconded the following resolution:—"That in view of the importance of research in the national interests and its value in post-graduate training, it is a matter of deep regret that external students of the University should not be permitted to take the Master's degree by means of research." After an animated discussion the resolution was passed, *nemine contradicente*, in an unusually large house, only three of those present refraining from voting in its favour.

MANCHESTER.—The University Court has agreed to the conferment of the following honorary degrees:—

Litt.D.—C. H. Haskins, Gurney professor of history and political science, and Dean of the Graduate School, Harvard University; S. Reinach, Membre de l'Institut de France, Conservateur du Musée de Saint Germain, professeur à l'Ecole du Louvre; J. T. Sheppard, fellow and tutor, King's College, Cambridge. *D.Sc.*—R. Kidston, author of numerous investigations in palæobotany; C. S. Sherrington, professor of physiology, Oxford, and president of the Royal Society.

The following degrees were conferred on May 7:—

Litt.D.—Sir Sydney J. Chapman, formerly Stanley Jevons professor of political economy in the University; Dr. C. H. Herford, professor of English literature in the University; Dr. T. W. Rhys Davids, formerly professor of comparative religion in the University; Dr. G. Elliot Smith, formerly professor of anatomy in the University. *D.Sc.*—Dr. Horace Lamb, formerly Beyer professor of mathematics in the University; Sir Ernest Rutherford, formerly professor of physics in the University. Dr. Horace Lamb, Dr. T. W. Rhys Davids, and Sir William Thorburn have been appointed professors emeriti.

THE University of Glasgow is to confer the honorary degree of LL.D. upon Mr. Laurence Binyon, of the British Museum, Sir Dugald Clerk, and Principal J. C. Irvine, of St. Andrews.

PROF. A. D. ROSS, professor of mathematics and physics in the University of Western Australia, Perth, has been elected a member of the governing body of the University. He formerly held office as Vice-Chancellor, but resigned from that post some little time ago.

THE Universities Institute and Institute of Lecturers are issuing a periodical, the *Platform Review*, the first number of which has reached us. The objects of the institute are to foster popular lecturing of an educational nature and to organise courses of such lectures. The first issue of its publication is a special lecturers' number, in which brief paragraphs appear giving accounts of the types of lectures which may be expected from a number of men who will be lecturing during the coming winter. All communications should be addressed to the Editor, 35 Cambridge Road, Seaforth, Liverpool.

Calendar of Scientific Pioneers.

May 12, 1684. Edmé Mariotte died.—An independent discoverer of Boyle's or Mariotte's law, Mariotte was prior of St. Martin-sous-Beaune. He was one of the earliest members of the Paris Academy of Sciences, and wrote on percussion, heat, colour, and hydraulics.

May 12, 1884. Charles Adolphe Wurtz died.—President of the Paris Academy of Sciences and holding the chair of organic chemistry in the Sorbonne, Wurtz wrote more than a hundred memoirs, and during 1869–78 published a great dictionary of pure and applied chemistry.

May 12, 1910. Sir William Huggins died.—The son of a London linendraper, Huggins after a few years in business retired and built an observatory at Tulse Hill, where he carried out pioneering work in astronomical spectroscopy and photography. He received the Rumford and Copley medals, and in 1900 became president of the Royal Society. Lady Huggins, who was his devoted assistant, died on March 24, 1915.

May 13, 1832. Léopold Chrétien Frédéric Dagobert, Baron Cuvier died.—Foremost among comparative anatomists, Cuvier was born in 1769. In 1795 he became a professor in the Jardin des Plantes, and in 1803 permanent secretary to the Paris Academy of Sciences. His most famous work, "Le Règne Animal distribué d'après son Organisation," appeared in 1817.

May 13, 1878. Joseph Henry died.—An indefatigable experimentalist, Henry made some of the earliest discoveries in electro-magnetism and electrical induction. He was professor of natural philosophy at Princeton from 1832 to 1846, and then became secretary to the Smithsonian Institution, which under his direction became one of the most important scientific institutions in the world.

May 13, 1891. Alexandre Edmond Becquerel died.—Professor of physics in the Conservatoire des Arts et Métiers and in the Musée d'Histoire Naturelle, Becquerel collaborated with his father in much of his work, and made independent researches on phosphorescence and on the electrical and magnetic properties of substances.

May 14, 1734. Georg Ernst Stahl died.—After holding the chair of medicine in the University of Halle, Stahl became physician to the King of Prussia. To explain the phenomena of combustion and calcination he formulated the theory of phlogiston.

May 14, 1893. Ernst Eduard Kummer died.—Born in 1810, Kummer was professor of mathematics in the University of Berlin. His writings referred mainly to branches of pure mathematics such as the theory of numbers.

May 14, 1899. Lars Fredrik Nilson died.—While professor of analytical chemistry at Upsala Nilson studied the rare earths, and in 1879 isolated scandium, an element identical with Mendeléeff's hypothetical element ekaboron.

May 16, 1830. Jean Baptiste Joseph Fourier died.—One of the savants who accompanied Bonaparte to Egypt in 1798, Fourier for some years was Prefect of the Department of the Isère. He succeeded Delambre as secretary of the Paris Academy of Sciences. His fame rests chiefly on his "Théorie Analytique de la Chaleur," containing the well-known Fourier's series so constantly used in modern analysis.

May 17, 1765. Alexis Claude Clairaut died.—A writer of mathematical papers at twelve and a member of the Paris Academy of Sciences at eighteen years of age, Clairaut has been called by Comte the principal constructor of celestial mechanics.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, May 5.—Prof. C. S. Sherrington, president, in the chair.—Dr. H. **Head**: Release of function in the nervous system (Croonian lecture). Hughlings Jackson's law that destructive lesions do not cause positive effects, but induce a negative condition, which permits positive symptoms to appear. Control of higher over lower centres. Structural lesions may remove this dominance and so reveal the activity of subordinate centres; this is "disintegration" of function. Should the stimulus become abnormally intense or central resistance be weakened, forms of reaction may break through which are normally suppressed; this is "escape from control."

Physical Society, March 22.—Prof. W. Eccles, vice-president, in the chair.—W. N. **Bond**: The effect of viscosity on orifice flows. Determinations were made of the coefficient of discharge through an orifice 0·1469 cm. in diameter of solutions of glycerine and water, varying in kinematic viscosity from 0·01 to 7. The results are plotted in a manner which combines both purely viscous and purely turbulent flows in one graph. The effect of slight viscosity is to increase the coefficient of discharge.—Dr. A. **Griffiths** and Constance H. **Griffiths**: Viscosity of water and low rates of shear. The determination of the coefficient of viscosity of water by a method in which water is forced along glass capillary tubes of 1·5 to 2·0 mm. bore at rates of flow varying from 1 litre in two years to 1 litre in twenty-four years. The liquid fills a closed tubular circuit which for purposes of description may be said to be rectangular in shape, two of the tubes being horizontal and two vertical. The circulation is caused by a difference of density obtained by having a weak solution of uranine in one vertical tube and pure water in the other. Values for the coefficient of viscosity are given. There is no experimental evidence that at the extremely low rates of shear the viscosity of air-free water in glass capillary tubes differs from its value at normal rates of shear.—B. S. **Smith** and G. F. **Partridge**: A method of measuring frequencies. A heterodyne method of measuring frequency by comparison with a calibrated valve oscillator. Calibration is performed by means of two valve oscillators capable of giving frequencies of 1000/sec. upwards. The frequency of the oscillations is raised alternately to give a beat note the pitch of which is determined by comparison with a fork. Intermediate frequencies are found by interpolation on the calibration curve. For the measurement of acoustic frequencies the sounds are converted into alternating currents by a suitable transmitter.

Geological Society, April 20.—Mr. R. D. Oldham, president, in the chair.—J. A. **Douglas**: Geological sections through the Andes of Peru and Bolivia. III.: From Callao to the River Perene. The zone of Mesozoic rocks extends to the Pacific coast, which is here formed of shallow-water deposits of Lower Cretaceous age. The granodioritic batholite which forms the core of the Andes is encountered in the neighbourhood of Lima, and again near the summit of the range. The western flanks of the Cordillera are characterised by a great development of Cretaceous porphyritic agglomerate; while the normal calcareous facies is the dominant feature of the high-level regions. The intensity of the Tertiary folding has obscured the effects of the post-Jurassic uplift previously shown to occur in the south, and it is only on palæontological evidence that a break in the sequence of Mesozoic deposits can be determined. The rocks of Palæozoic aspect which form the eastern flanks of the Cordillera are mostly unfossiliferous, and have largely been converted into phyllites and mica-schists, penetrated by granite. On the Rio Perene a bigger mass of red granite is found, which is essentially a rock of "alkaline" character. It is suggested that its origin is antecedent to the uplift of the mountain ranges.—Prof. O. T. **Jones**: The Valentian series. The history of the nomenclature from the time of Murchison onwards was traced and the relation of the Tarannon to the Llandovery and the Birkhill-Gala rocks discussed in detail. In view of the occurrence of two distinct facies (graptolitic and shelly) of the Valentian rocks, two separate classifications are in use. The succession of graptolites is made the basis of one of these, the series being divided into a Lower or Birkhill stage and an Upper or Gala stage, each of which is further divided into sub-stages and zones. The mixed facies of Girvan allows certain shelly horizons to be brought into relation with the graptolitic scale. The fauna of various districts where the shelly facies prevails is compared with the Girvan succession and a general correlation-table of the Valentian rocks proposed, the rocks of the shelly facies being divided into two stages—Lower and Upper Llandovery. The base-line of the Valentian series was discussed, and in most districts evidence is found of an abrupt lithological change at a certain horizon, which in some cases amounts to a palæontological break. The phenomena at that horizon suggest arrested sedimentation, if not also actual erosion.

PARIS.

Academy of Sciences, April 18.—M. Georges Lemoine in the chair.—J. **Boussinesq**: The flattening along the polar axis, by surface tension, of a liquid drop, of revolution and without weight, possessing a given angular velocity ω of rotation round this axis.—E. **Bourquelot** and M. **Bridel**: The application of the biochemical method of research on glucose to the study of the products of fermentation hydrolysis of inulin. By the hydrolysis of inulin by the inulase from *Aspergillus niger* reducing products are obtained which possess the rotary power of *d*-fructose, and do not combine with methyl alcohol under the influence of emulsin. It is concluded that the hydrolytic fermentation of inulin gives no glucose.—L. **Cuénot**: Regeneration of claws in the place of antennæ removed by cutting in a Phasmid.—B. **Gambier**: Non-unicursal algebraic curves with constant torsion.—L. **Montangerand**: Observation of the eclipse of the sun on April 7, made at Toulouse Observatory.—A. **Véronnet**: The constitution and formation of the spiral nebulæ. A mathematical investigation of the conditions under which a double star formed of two components of large, homogeneous, and approximately equal masses may lead to the formation of a spiral nebula.—H. **Chipart**: The homologues of a permanent uniformly magnetised magnet. The law of the ellipsoid.—L. and E. **Bloch**: The spark spectra of gold and platinum in the extreme ultra-violet. Tables of wave-lengths of the lines of the spark spectra of these two metals are given between the limits 1843 and 1402.—A. **Portevin**: The use of very slow cooling for the micrographical study of alloys and the structure of the tungsten steels. The advantages of the very slow cooling are that the structure of the alloys appears on a larger scale, permitting projection on the screen with relatively low magnification, and sometimes new, unsuspected equilibrium structures are shown. The case of tungsten steels is considered in detail, and two photomicrographs of these alloys are reproduced.—M. **François**: A microscopic arrangement for the examination of opaque crystals.—G. **Dubreuil**: The principle of a new method of graphical

stereoscopic reconstruction of magnified microscopic objects.—A. **Duboin**: The constitution of smalt. Details for the preparation of this colouring matter are given, the analysis of which leads to the formula $K_2O,CoO,3SiO_2$ as representing its composition.—G. **Claude**: The manufacture of hydrogen for the synthesis of ammonia. With a view to the utilisation of hydrogen from water-gas, experiments on the solubilities of hydrogen and carbon monoxide in various solvents at high pressures (up to 1600 atmospheres) and at varying temperatures were carried out. A diagram is shown giving the results of the solubility experiments for hydrogen and carbon monoxide at 20° C. and -40° C. in ether. It is concluded that by using ether the commercial separation of these two gases under pressures of about 100 atmospheres and temperatures of the order of -50° C. would easily give hydrogen containing less than 0·2 per cent. of carbon monoxide.—M. **Vèzes**: The composition of French turpentine. The proportions of pinene and nopinene are determined by a polarimetric method.—L. **Palfray**: The cresyl cyanocampholates and their reduction product.—R. **Cornubert**: The oxidation with permanganate of αα-methylallyl*cyclo*hexanone in alkaline solution.—E. **André**: The determination of the acetyl figure of fatty materials. A simplification of the Lewkowitsch method.—L. **Cayeux**: The existence of numerous halcyon spicules in the Jurassic iron minerals of France.—P. **Russo**: The geological situation of the volcanoes of Oudjda, eastern Morocco.—M. de Montessus **de Ballore**: The longitudinal depression of Chile.—L. **Blaringhem**: The variations and fertility of the hybrid *Primula variabilis* compared with those of its parents, *P. vulgaris* and *P. officinalis*.—P. **Dangeard**, jun.: The evolution of the aleurone grains in ordinary vacuoles and the formation of tannins.—L. **Destouches**: The prolongation of life in *Galleria mellonella*. At the most favourable temperature, 37° C., the total evolution of the caterpillars of Galleria from the egg to the butterfly is about fourteen days. This period can be progressively lengthened by lowering the temperature. By submitting the caterpillars for periods of twenty-four hours alternately to temperatures of 1° C. and 37° C. the life can be prolonged to thirty-five days, and at the same time the production of eggs is more than doubled.—L. **Mac-Auliffe** and A. **Marie**: An anatomo-physiological study of a Japanese method of abdominal massage.—A. **Peyron**: The mode of development and the varieties of tumours of the ovotestis.—J. **Legendre**: The biology of the Madagascan perch.

ROME.

Reale Accademia nazionale dei Lincei, February 20.—Original papers by fellows:—G. **Castelnuovo**: Abelian functions, ii.: The geometry of Abelian varieties.—C. **De Stefani**: Ligurian siliceous sponges, iv.: Eocene, lower strata, valley of the Iso and Cairo (Italy).—A. **Issel**: First steps in the systematic arrangement of geological marks. The author proposes to divide them into nine classes, namely, cosmic marks (meteorites), atmospheric marks, hydrospheric marks, hydro-mineral marks, volcanic marks, tectonic marks, plutonic marks, glacial marks, and physiological marks.—Papers communicated through fellows:—L. **Tonelli**: Two propositions of Lindeberg and Levi in the calculus of variations, ii.—O. **Lazzarino**: Variations in kinetic energy of a semi-rigid rotating system.—M. **Pascal**: Superficial circulation, ii. Vectorial expressions and general theorems analogous to ordinary circulation theories.—C. **Perrier**: The true nature of Rosasite. This mineral, discovered in a mine at Rosas, in Sardinia, in the form of crystals, is mainly compounded of copper oxide, copper carbonate, and zinc carbonate.—E. **Bora**: Contributions to the natural history of Anopheles and their extermination (in connection with Prof. B. Grassi's anti-malaria campaign at Fiumicino, near Rome), iii. The author gives statistics regarding the hours of the day and night at which the mosquitoes enter buildings and commence their attacks. It appears that they rarely attack until some time after their entry. In a second part of the note the author gives evidence in support of the view that fishes and ducks are inefficacious in attacking and keeping down the larvæ.—A. **Lo Surdo**: Binaural localisation of pure sounds. In order to test the theory according to which perception of the direction of a source of sound is due to the difference of phases of the waves as they reach the two ears, the author has constructed an experimental apparatus in which a source of sound is connected with the ears by two tubes, one of which at least can be varied so as to be made longer or shorter than the other at will. If the difference of path is less than half a wave-length, the sound appears to come from a source in the direction of the shorter path; if the difference is exactly equal to a wave-length, the source appears to be in front, and, as should be expected from theory, the apparent direction of the source now varies when one path is increased or decreased in just the same way as it would vary if we started with the two paths equal.—The Secretary (Prof. Castelnuovo) announced that ten candidates submitted works in competition for the prize for physical and chemical sciences offered by the Minister of Public Instruction, and one candidate for the Carpi prize.

Books Received.

The Man who Did the Right Thing: A Romance of East Africa. By Sir Harry Johnston. Pp. vii+444. (London: Chatto and Windus.) 8*s*. 6*d*. net.

The Elements of Illuminating Engineering. By A. P. Trotter. (Technical Primers.) Pp. xi+103. (London: Sir I. Pitman and Sons, Ltd.) 2*s*. 6*d*. net.

Diary of Societies.

THURSDAY, MAY 12.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. C. S. Myers: Psychological Studies: (2) The Appreciation of Music.

HARVEIAN SOCIETY OF LONDON (at Paddington Infirmary), at 4.30.—Clinical Meeting.

INSTITUTE OF PATHOLOGY AND RESEARCH (St. Mary's Hospital, Paddington), at 4.30.—Sir James Mackenzie: The Opportunities of the General Practitioner are Essential for the Investigation of Disease and for the Progress of Medicine.

ROYAL SOCIETY, at 4.30.—G. W. Walker: The Problem of Finite Focal Depth revealed by Seismometers.—E. A. Griffiths: A Liquid Oxygen Vaporiser.—Dorothy M. Palmer and W. G. Palmer: Some Experiments on the Catalytic Reduction of Ethylene to Ethane.—W. G. Palmer: The Catalytic Activity of Copper. Part II.—Prof. J. F. Jenkin and D. N. Shorthose: The Total Heat of Liquid Carbonic Acid.—Dr. A. O. Rankine: The Viscosity and Molecular Dimensions of Gaseous Cyanogen.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—H. W. Turnbull: Invariants of Three Quadrics.—G. H. Hardy and J. E. Littlewood: (1) Some Problems of Diophantine Approximation; (2) The Lattice Points of a Right-angled Triangle (Second Paper).

CHILD-STUDY SOCIETY (at 90 Buckingham Palace Road), at 6.—Discussion on Individual Training.—Miss F. E. Webb: Individual Training in the School.—Miss Sabina Salt: Preparation in the Training College for Individual and Group Work in the School.—Miss C. M. A. Coombs: Vertical Classification in an Infants' School.

SOCIOLOGICAL SOCIETY AND REGIONAL ASSOCIATION (at 65 Belgrave Road), at 8.15.—Prof. P. Geddes: Co-operation in Social Studies.

ROYAL SOCIETY OF MEDICINE (Neurology Section) (Annual General Meeting), at 8.30.—Prof. Marinesco: Encephalitis Lethargica.

FRIDAY, MAY 13.

ROYAL ASTRONOMICAL SOCIETY, at 5.—A. N. Brown: Observations of V Cassiopeiæ (Ch. 8324) in 1916-21.—A. A. Rambaut: Observations of the Solar Eclipse of 1921, April 7, at the Radcliffe Observatory, Oxford.—W. H. Van Den Bos: The Orbit of Σ 554=80 Tauri.—Rev. A. L. Cortie and Rev. J. Rowland: The Partial Eclipse of the Sun, 1921, April 7.—C. Martin and H. C. Plummer: Magnitude Curves of Three Short-period Variable Stars, RR Leonis, Y Aurigæ, and UU Cassiopeiæ.—Royal Observatory, Greenwich: Observations of the Solar Eclipse of 1921, April 7.—Royal Observatory, Greenwich: Observations of Comets, 1921, *a*, *b* (Reid and Pons-Winnecke).—L. J. Comrie: Eclipse of Rhea by the Shadow of Titan.—Dr. T. Royds: Lantern Slides illustrating Recent Work at the Kodaikánal Observatory.—Prof. W. H. Pickering: Observations of the Moon at the Harvard College Observatory, Jamaica.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science and Technology), at 5.—L. Hartshorn and E. S. Keeping: Notes on Vacuum Tubes used as Detectors of Electrical Oscillations.—B. W. Clack: The Coefficient of Diffusion of Certain Saturated Solutions.—Dr. G. D. West: Experiments on Thermal Transpiration Currents.

INSTITUTE OF TRANSPORT (at Royal Society of Arts), at 5.

ROYAL SOCIETY OF MEDICINE (Clinical Section), at 5.30.—Annual General Meeting.

JUNIOR INSTITUTION OF ENGINEERS, at 8.—H. G. Brown: Scientific Developments in Gas Measuring Instruments.

ROYAL SOCIETY OF MEDICINE (Ophthalmology Section), at 8.30.—Dr. D. L. Davies: Lachrymal Obstruction, Results of Anastomotic Method of Treatment (Toti).—E. Clarke: Lessons from Forty Years of Refraction Work.—Miss J. C. Mann: Aphakia in a Human Embryo of Five or Six Weeks.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. W. Bateson: The Determination of Sex.

SATURDAY, MAY 14.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. E. C. C. Baly: Chemical Reaction.

TUESDAY, MAY 17.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—E. Clodd: Occultism: Its Origin and Development.

WEDNESDAY, MAY 18.

ROYAL HORTICULTURAL SOCIETY, at 3.

ROYAL METEOROLOGICAL SOCIETY, at 5.—J. E. Clark and H. B. Adames: Report on the Phenological Observations for 1920.—Dr. E. J. Salisbury: Phenology and Habitat, with Special Reference to the Phenology of Woodlands.

ROYAL SOCIETY OF MEDICINE (History of Medicine Section) (Annual General Meeting), at 5.—Dr. C. G. Cumston: A Brief Historical Summary of the Treatment of Trachoma, with Special Reference to the Arabian School and the Writings of Ali Ibu-el-Aïssa.

ROYAL SOCIETY OF MEDICINE (Surgery Section) (Annual General Meeting), at 5.30.

ROYAL MICROSCOPICAL SOCIETY, at 8.

THURSDAY, MAY 19.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—E. Law: The Architecture and Art of Hampton Court Palace: In Tudor Times.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital, Paddington), at 4.30.—Dr. H. H. Dale: Anaphylaxis and Immunity.

ROYAL SOCIETY OF MEDICINE (Dermatology Section) (Annual General Meeting), at 5.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—E. H. Clifford: Scheme for Working the City Deep Mine at a Depth of 7000 ft.—The following Papers will be submitted for Discussion:—F. P. Caddy: Stope Measuring at the Passagem Mine of the Gold Mines of Ouro Preto, Ltd.—J. A. P. Gibb: Notes on Some Useful Alignment Charts.

CHEMICAL SOCIETY (Informal Meeting), at 8.

RÖNTGEN SOCIETY (in Physics Lecture Theatre, University College), at 8.15.

FRIDAY, MAY 20.

ROYAL SOCIETY OF MEDICINE (Otology Section) (Annual General Meeting), at 5.—F. J. Cleminson: Sinusitis in Children.

ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section) (Annual General Meeting), at 8.30.—Discussion: The Stomach.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. E. H. Starling: The Law of the Heart.

SATURDAY, MAY 21.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Legge: Gnosticism and the Science of Religions.

The Treatment of Tuberculosis by Public Authorities.

THE Tuberculosis Bill introduced by the Ministry of Health having passed through the House of Commons without material amendment, it may be assumed that it will become law. It is an important enactment in its actual provisions, and interesting because it constitutes an attempt to retrace the erroneous steps taken when the National Insurance Bill became law in the year 1911.

Under the National Insurance Act the sanatorium benefit was perhaps the most popular provision, with the possible exception of the maternity benefit. The sanatorium benefit was boomed in the discussions on the Bill until the idea became fixed in the minds of the general population that a first-class hotel in favoured rural surroundings was to be available for every insured consumptive with a reasonable prospect of the cure of his disease. The limitations and the extent of utility of sanatoria in the treatment of tuberculosis were even then well recognised by physicians; but the ideas of Insurance Committees were of a different order, and the pressure brought to bear on these committees by insured persons was so great that many thousands of patients, suitable only for attention in hospitals, were treated in sanatoria, while accommodation for earlier curable cases was deficient in amount. The sanatorium benefit provided also dispensary and domiciliary treatment for insured persons, and in the latter respect encroached on the treatment given by the panel doctors. There was the further difficulty that in counties and county boroughs, the public health committees of which had made provision for the institutional treatment of the entire population, insured persons were in a position but little better than that of the non-insured, except in respect of treatment at home.

The fundamental mistakes in the making of these provisions were such as were almost inevitable when amateur medical and lay opinion took the place of skilled advisers having administrative experience in the treatment and prevention of tuberculosis and in general public health work, of which the prevention of tuberculosis forms an essential part. The best that can be said for the actual provisions of the Insurance Act is that it hurried on the general provision of anti-tuberculosis measures, and that especially the associated large grant for the erection of tuberculosis institutions helped to this end. It is necessary to add that had enactments similar to those now embodied in the Tuberculosis Bill been substituted for the extravagant and inefficiently redundant services provided under the Insurance Act, the efforts of public health authorities would have been much more efficient, the friction of duplicated work would have been avoided, and the present position in regard to the treatment and prevention of tuberculosis would be much more satisfactory than it is.

It must not be assumed that the present measure represents all that is necessary for a rapidly successful, because complete, crusade against tuberculosis. It removes from the Insurance Committees responsibilities which they should never have possessed; it agrees to regard as "adequate" those arrangements by the councils of counties and county boroughs for the treatment of tuberculosis which have already received Governmental approval (many of these arrangements are imperfect and incomplete); it makes it obligatory on the councils of counties and county boroughs which have not already made "adequate" arrangements to do so at once, on pain of action at their expense by the Ministry of Health if they default; and it gives power for the provision of after-care and for setting up joint committees when necessary.

All familiar with the actual state of tuberculosis administration in this country know how partially and imperfectly our present knowledge for the treatment of this disease is being utilised.

The war is doubtless responsible for this in part; the divided responsibility of poor law, public health, and insurance authorities has seriously contributed to the same result; and until poor-law hospitals become available generally for non-pauper advanced and acute consumptives there will still persist on a large scale failure to utilise to the utmost already existing arrangements for the hospitalisation of those consumptives whose continued residence in small dwellings, where good nursing and good hygiene alike are impracticable, is a chief reason why our national death-rate from tuberculosis is not declining so rapidly as it can be made to do.

It is unfortunate that in the campaign for the better housing which is so badly required no importance has been attached—apparently from lack of penetration or knowledge—to the fact that, so far as the problem of tuberculosis is concerned, a great, and the most urgent, contribution to the housing problem consists in securing attractive hospital beds for those advanced and acute cases of tuberculosis which are now treated at home under unsatisfactory conditions.

Health and Work.

The Health of the Industrial Worker. By Prof. E. L. Collis and Dr. Major Greenwood. Containing a chapter on Reclamation of the Disabled, by Dr. A. J. Collis. With an Introduction by Sir George Newman. Pp. xix + 450. (London: J. and A. Churchill, 1921.) 30*s*. net.

Many books have been written on the diseases of occupations, but this is the first adequate modern treatise upon the hygiene of industry in general. A more ideal combination of authors for the purpose it would be difficult to find. Prof. Collis, professor of preventive medicine in the Welsh National School of Medicine, was formerly one of H.M. Inspectors of Factories; during the war he served as Director of Welfare and Health in the Ministry of Munitions and was an active member of the Health of Munition Workers Committee. Dr. Greenwood, who is reader in medical statistics in the University of London, was in charge of the Medical Research Branch of the Ministry of Munitions during the war. By his refinements and judicious application of statistical methods he has done more than anyone else in this country to discourage the issue of statistically worthless medical and physiological data. Both authors are members of the Industrial Fatigue Research Board, and they have made full use in their book of the valuable reports published by the Board.

As they point out, the keynote of the nineteenth century was the discovery of the industrial value of the inanimate machine; while the keynote of the twentieth century will prove to be the discovery of the industrial value of the living, intelligent worker. They indicate the relation of the early epidemics of plague and typhus to want and overcrowding, and the effects of the now restricted employment of children in improving physique and reducing birth-rate. They describe the medieval measures in this country to prevent the worker from changing his trade and from leaving his district; they show the far greater protection now afforded by the law to women than to men workers; and they point out the opposition which each legislative advance has had to meet before it was finally countenanced.

The very thoughtful chapter on the utilisation of statistical methods in industrial preventive medicine deals with the fallacies of comparing average ages at death, the methods of standardisation, and proportionate mortality in vital statistics. A well-founded plea is advanced for the instruction of medical students in the elements of statistics.

Chap. vi. contains a fascinating epidemiological inquiry into phthisis, especially valuable for its keenly critical and temperate character. The greater decline of phthisis among women than among men in the past fifty years is attributed to the more potent influence of factory conditions on the latter, so that they react more readily than the women to the home influences of overcrowding and of poor (? vitamin-poor) diet. Stress is laid on the importance of viewing industrial phthisis from the industrial aspect, sanatorium treatment being useless unless combined with suitable and remunerative occupation for the skilled convalescent craftsman and with organised methods to nurse the patient back to his proper industrial sphere.

The next chapter discusses the increasing death-rate from cancer. The authors regard the remarkable increase between 1900 and 1913 as being too great to be attributable to improved methods of diagnosis. Evidence is adduced that the prevalence of cancer is connected with industrial conditions, and that, *ceteris paribus*, its frequency is greater in cities and among males.

The striking statistical regularity of accidents is demonstrated in chap. viii., comparable to that of the frequency curves of disease. The maximal reduction in accident-rate, obtainable by the better safeguarding of machinery, is estimated

at only 10 per cent. The workers' conservatism in wearing loose clothes, in displaying loose hair, and in objecting to the use of goggles, and their diverse mental constitution which renders certain of them especially liable to accidents, afford illustrations of the importance of a psychological study of accident determination. "The psychical factor," we are rightly told, "is one of the most important in accident causation."

Chap. ix. deals with the industrial employment of women. From it we learn how man invaded woman's primitive concern in industry when hunting and fighting began to wane. No evidence is forthcoming that woman's present work in factories is more arduous than it was in times preceding the Industrial Revolution.

In the course of the remaining eight chapters useful illustrations are given of canteen menus, washing and drinking appliances, seats, and overalls; and a final chapter on reclaiming the disabled, by the Medical Superintendent of the Ministry of Pensions Hospital at Leicester, brings this original and invaluable work to its conclusion.

Invaluable it cannot fail to prove to him who desires a lucid, critical, and temperate summary of our knowledge in any one of the many fields above referred to, or who seeks a list of references to guide his further reading. Only one defect may perhaps be suspected, namely, that the authors have not kept fully abreast of recent advances in the physiology of the neuro-muscular system and in our psychological outlook on the worker. Thus, in discussing the physiology of muscular contraction, they ignore the recent work of Lucas, Adrian, and others, as a result of which physiologists are now chary of supposing that the strength of an impulse along a given nerve-fibre is variable, or that the staircase (*treppe*) phenomenon is due to practice. The authors' invariable use of the term "end-organ" when they mean "end-plate" may also indicate some lack of freshness in dealing with the same problem. Their informing chapter on alcohol reveals an inability to distinguish between the physiological and the psychological, or else a desire to ignore the latter. "First," they say, "we have to notice some simple physiological or rather psycho-physiological results." But when we come to these results we discover them to be neither simple nor physiological, but to be the outcome of a study of the effects of alcohol on the psychological processes (the physiological bases of which are quite unknown to us) of learning Latin hexameters, and of using the typewriter and the adding machine. The authors, apparently for similar reasons, give us no account of the perhaps more valuable and more purely psychological investigations on the subject by Prof. McDougall and Miss May Smith, published last year by the Medical Research Council. They even apologise for discussing the psycho-neuroses, whereas apology is due for their brief treatment of so important an industrial subject. They refer only to the work of Breuer (misspelt Bruer) and Freud (published in 1895!), and they are concerned merely with such hysterical manifestations as disturbances of locomotion and speech, neglecting the far commoner and more important anxieties, fears, and mild obsessions which so strikingly affect industrial efficiency.

The truth must be faced that no one writer and no one "certifying surgeon" can combine in himself a knowledge of canteen management, dentistry, eye and limb injuries, pulmonary and other diseases, vital statistics, and industrial psychology. Hitherto the recognition and the prevention of mental disturbance have been ignored as completely in industry as they have been in crime. The prevalence of the psycho-neuroses among workers has not been evident because it has never been looked for, and because until recently no adequate treatment was available for it.

In other respects this book reaches an exceptionally high standard. The defects to which we have directed attention are only slight blemishes, if the wide scope of the work be taken into consideration. They should be easily remediable in the subsequent editions which its assured popularity is certain to evoke.

CHARLES S. MYERS.

British Stratigraphy.

Handbuch der Regionalen Geologie. Herausgegeben von Prof. G. Steinmann und Prof. O. Wilckens. 20 Heft, iii. Band, 1 Abteilung. *The British Isles: The Channel Islands.* By thirteen contributors. Local editor, Dr. J. W. Evans. Pp. 354. (Heidelberg: Carl Winters Universitätsbuchhandlung, 1917.) 15*s*.

THIS book is remarkable both in contents and in origin. An excellent survey of the whole range of British stratigraphy by a group of highly qualified British authorities, it was published in Germany by German publishers in the very thick of the war (1917). It is part of an ambitious scheme, planned in Germany before the war, to embrace the geology of the whole earth in a series of separate "handbooks" by specialists writing in one of the three languages, German, French, or English. The separate parts were to be combined into volumes, of which the prospective size may be gauged when we take note that the substantial volume before us is part i. of vol. iii.; with France, Spain (already

published), and Portugal as the other parts. Of the fifty-eight parts projected, twenty-one were shown as published when the present volume appeared; but these treat mostly of the smaller European countries and of regions beyond Europe, while the parts to be devoted to Germany, Austria, Hungary, etc., not to speak of those relating to France, Italy, Belgium, Switzerland, etc., were still lacking. This suggests that the German plans, in this as in other matters, have been found easier than the German performance.

For what we have received, however, let us be thankful. In the present part we have a most useful and authoritative summary of our geological knowledge of the homelands. The local editor, Dr. J. W. Evans, has skilfully selected his team, who have dealt individually with the formations on which they have specialised, and possess the fullest and latest information. There is, of course, some unevenness of treatment, but the general scheme is coherent throughout. The classification, subdivision, and local variation of each system in turn are broadly described without much local detail, and illustrated by sketch-maps and sections (mostly reproduced from previous publications, but here conveniently assembled) and by full correlation-tables. The names of the authors of the chapters are sufficient guarantee for the quality of the work. Prof. W. W. Watts deals with the pre-Cambrian, Cambrian, and Ordovician rocks of England; Prof. J. W. Gregory with the pre-Cambrian of Scotland, as well as with the morphology; Dr. A. Harker with the igneous rocks, in a series of short articles under the formational headings; Dr. A. Morley Davies with the morphology of England and Wales, and with the Jurassic and Cretaceous rocks of Britain, except portions of the Scottish Jurassics which are described by Prof. P. G. H. Boswell along with the Scottish Trias; Prof. O. T. Jones with the Silurian; Dr. J. W. Evans with the Devonian; Prof. P. F. Kendall with the Carboniferous, Permian, and Quaternary deposits; Mr. L. Richardson with the Trias and Rhætic; Mr. H. J. Osborne White with the Upper Cretaceous and Tertiary; Prof. G. A. J. Cole with the whole of the Irish formations and with Irish morphology; and Mr. J. Parkinson with the Channel Islands. Room is also found for a short chapter on British earthquakes by Dr. C. Davison.

It is inevitable that there will be many individual points in an embracing work of this kind on which one reader or another will feel inclined to challenge the authority; one might take exception, for example, to the inclusion of the Albian in the Lower Cretaceous, after the unfamiliar German practice, and to the unwarranted implication here and there that German usage is equivalent to "Continental usage." But we have no space for criticism of detail, which would, indeed, in most cases resolve itself merely into the statement of difference of opinion upon minor points. We commend the book to the attention of every advanced student of British geology.

G. W. L.

Chemical Research in the Elementary Laboratory.

The Experimental Basis of Chemistry: Suggestions for a Series of Experiments Illustrative of the Fundamental Principles of Chemistry. By Ida Freund. Edited by A. Hutchinson and M. Beatrice Thomas. Pp. xvi+408. (Cambridge: At the University Press, 1920.) 30*s*. net.

MISS FREUND'S "Study of Chemical Composition" has established for itself a position in chemical literature which has many of the elements of permanence, mainly because of the abiding charm and freshness of the contact which it gives with the great pioneers of chemical discovery. To repeat this successful adventure in a laboratory manual of practical chemistry would appear to be a much more formidable task; but the ten chapters on "The Experimental Basis of Chemistry" which have been prepared for the Press by Mr. Hutchinson and Miss Thomas demonstrate the value, even in an elementary laboratory, of an intimate knowledge of and love for chemical literature.

The earlier portions of the book are of a missionary character. The gospel preached is that knowledge comes only by labour, and that the hasty and inexact work of a beginner is too insecure a foundation on which to base the laws of chemistry. The latter must be derived from the painstaking and exact work of the great masters of the science. In particular a protest is made against those aspects of the "heuristic" method of teaching in which the student is expected to discover in class laws and facts which would demand months and years of work if the discovery were only genuine. Even to prove the correctness of these laws and facts is usually beyond the ability of the worker, and all that is really possible is to work out (in the words of the sub-title) "a series of experiments illustrative of the fundamental principles of chemistry."

The experiments selected for this purpose include a considerable number which are new in form or method; but a more important feature of the book is the discussion of the limits of error as revealed by a comparison of the results of indi-

vidual workers with one another and with the results attained in the most exact researches. This leads up to a consideration of the conclusions that can be drawn from the work, or of the additional experiments that must be made before any conclusions can be drawn.

It is to be feared that those teachers who most need the stimulus and the criticisms of this book will be the last to read it; but many younger teachers, who have already tasted of the tree of knowledge, will find in the book fresh inspiration for the study of chemical discovery, and guidance as to its application in the daily routine of the school.

T. M. L.

Cocoa and Chocolate.

Cocoa and Chocolate: Their History from Plantation to Consumer, by Arthur W. Knapp. Pp. xii+210. (London: Chapman and Hall, Ltd., 1920.) 12*s.* 6*d.* net.

MR. A. B. WALKLEY has recently explained in his inimitable fashion how the whole future of the drama and dramatic art in England depends on the withdrawal of the rule that chocolates must not be sold in theatres after 8 p.m. A commodity which has such a profound, if indirect, influence on an important phase of English culture merits serious treatment, and it was clearly time that the history of cocoa and chocolate should be written, and written in a popular fashion.

When, about 1735, Linnæus coined for the cacao tree the picturesque name of *Theobroma cacao*, the English chocolate-making industry had been in existence about seven years. It made slow progress in its early days, and 100 years after its inception the imports of cacao beans amounted to only 450 tons per annum. Since then, and especially in the last ten years, the rise has been remarkable, the imports of the raw material for home consumption in 1919 being over 64,000 tons. In addition, there are considerable imports of foreign-made cocoa and chocolate. The chocolate-maker has, therefore, no reason to complain of the descent of chocolate from its lofty estate as a food of the "gods" to the more humble condition of the flapper's confection.

Mr. Knapp is connected with an enterprise which not only makes everything that can be made from cacao beans, but also owns plantations of cacao trees. He has had, therefore, unique opportunities of making himself acquainted with every branch of the industry, and he has clearly not only utilised these opportunities to the full, but also has thought to some purpose about the numerous unsolved problems connected with cacao-planting and the preparation of the beans for the market. There must be few planters whose ideas on the shading of cacao trees, the fermentation of the beans and the characteristics of a good cacao will not be clarified by a perusal of Mr. Knapp's pages.

Though chocolate is regarded by the ordinary person as a luxury, it has always had a band of devotees, who regard it as an important food-stuff. Mr. Knapp is one of these enthusiasts, and he provides the inevitable table, comparing the "fuel value" of chocolate with those of some ordinary foods. He omits, however, all reference to price per calorie, which would bring out the interesting fact that even plain chocolate is an expensive food, and that when consumed in the form of those super-confections which, if one may judge from the contents of chocolate-shop windows, constitute the bulk of the chocolate consumed to-day, it is a very expensive food—in fact, as the plain man believes, a luxury. The author of so interesting a book as this may, however, be forgiven a trifling obsession of this kind. It is a book which should be in the hands of all officials of tropical agricultural departments (for whose experimental work Mr. Knapp expresses much admiration) and of all cacao planters, and it is so simply and clearly written that it might even be read by the chocolate consumer if there were in this country any adequate machinery for making the existence of interesting technical literature known to the general public. The illustrations are numerous, good and well selected.

T. A. H.

Our Bookshelf.

An Introduction to Combinatory Analysis. By Major P. A. MacMahon. Pp. viii+71. (Cambridge: At the University Press, 1920.) 7*s.* 6*d.* net.

IN this little book Major P. A. MacMahon has given a short introduction to his two volumes on combinatory analysis which were published in 1915–16. The theories of combination, permutation, arrangement, order, and distribution which are dealt with in those volumes present technical difficulties; it is, therefore, a great advantage that such an introduction should exist, for the gradual development of the subject by easy stages will prove interesting to the reader and whet his appetite for the larger tomes which await him.

In the first chapter the elementary theory of symmetric functions is introduced, and on it the theory of distributions is afterwards based. The author treats in turn the simplest problems of the distribution of objects into boxes, one object

only being placed in each box, then the various complicated problems which result when the restrictions are removed, and finally the general problem of distributing s different sets of similar objects of which there exist p_1 of one kind, p_2 of a second kind . . . and p_s of another kind, into boxes of which there are m_1 of one kind, m_2 of a second kind . . . and m_t of another kind, the whole number of the boxes being any number not greater than the whole number of the objects.

It is a great achievement to expound a difficult subject in a simple manner, and for that reason alone Major MacMahon is to be congratulated. For some reason which is not at present clear, the theory of the combination of different sets of similar possibilities (which can conveniently be represented as the distributions of balls in boxes) is of the utmost importance in many different branches of science. For example, it is clear that this theory must enter into such a question as the formation of a muddy liquid from molecules which occur in groups of one, two . . . n. The theory will also be relevant in a serious consideration of error in relation to causal laws. The subject is, therefore, of great importance in applied as well as in pure mathematics, and might very well prove another example of the extraordinary way in which abstract mathematics leads the way in applied science.

Dorothy Wrinch.

Il Regime delle Acque nel Diritto Pubblico e Privato Italiano. By Avv. Antonino Vitale. Pp. x+480. (Milano: Ulrico Hoepli, 1921.) 25 lire.

The rapidly increasing development of the water-power resources of Italy since the commencement of the war, and the probability of still further extensions in its use in the future, have led many writers in Italy to attempt a clear exposition of the legal aspect of the question, which is an extremely wide one, covering, as it does, the interests of the State, communities, and individuals. The author of the present work, Advocate Vitale, who is attached to the Ministry of Public Works, brings to his study a special competence. After a reasoned consideration of the question whether there exist private waters in contradistinction to public waters, or whether there is a private title to certain waterfalls as compared with the public title, he deals at length with the legal aspects of private title. The question of administrative control is treated in three large sections, the first of these bearing on the harnessing of water-power and the protective measures involved; the second on the actual utilisation and control of falls, rivers, and streams; and the last on contentious points of law and administration. In this survey all possible applications of water-power, including hydro-electric stations, irrigation plants, river diversions for water supply, transport, etc., have received consideration. The volume contains copious references to existing legislation on the subject and to the works of other authors. The main interest of the book is naturally to Italians, although, of course, existing and subsequent enactments would affect corporations and syndicates anywhere which might anticipate obtaining concessions for the development of water-power in Italy.

E. S. H.

A Text-book of Physics. By Dr. W. Watson. Seventh edition. Revised by Herbert Moss. Pp. xxvi+976. (London: Longmans, Green, and Co., 1920.) 21*s.* net.

The new edition of this well-known text-book is substantially a reprint of that of 1919. The additions made include the spherometer, Young's extensometer, the McLeod gauge for measuring low pressures, and the travelling microscope. The discussion of Young's modulus, Poisson's ratio, and rigidity has also been considerably amplified, while descriptions of the pyrheliometer, the Callendar continuous-flow method of mixtures, and the Beckman and clinical thermometers now find a place. Further additions include a proof of Gauss's theorem with illustrations, likewise illustrations of the applications of Kirchhoff's laws, and in electron theory a concise account of "canal" or positive rays. The explanation of diffraction through a slit has been extended, and "resolving power" is also treated.

The values of physical constants have been revised, and under "Terrestrial Magnetism" the majority of the maps and diagrams replaced by recent plottings. It is interesting to note therefrom that the east line of zero declination, or agonic line (1917), now consists of a nodal curve with intersecting branches, in place of the former simple curve and Siberian oval, as in 1907.

In its present form Watson's "Physics" is the most comprehensive single-volume text-book of physics in the English language. It contains little that may now be adversely criticised, and the compilers have improved the index by increasing it to nearly twelve pages.

A. W. Bain.

La Colloidothérapie: Résultats Cliniques. By Dr. J. Laumonier. (Collection Médicale.) Pp. ii+283. (Paris: Félix Alcan, 1920.) 5.50 francs.

This book, as its title suggests, has been written by one who has no doubts as to the answer to a question which gives pause to many—namely, whether any special therapeutic value can be assigned to preparations of metal and other substances in the colloidal state which can be attributed to their state.

The theoretical section is commendably brief, the main body of the work being devoted to a systematic account of the method of preparation, uses, and physiological action of colloidal solutions of silver, gold, platinum, arsenic, etc.

The author's reading is limited, and his references are confined practically solely to the work of his compatriots; but the work of the French school affords ample material for the object in view—namely, the production of a book of reference for the practitioner.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Magnetic Storm of May 13–17.

A TIME of unusually severe and protracted magnetic disturbance began on May 13, at about 13h. 10m. G.M.T., with an S.C. ("sudden commencement"). This was clearly oscillatory in D (declination), movements to west, east, and again west following in rapid succession, their extreme range being about 15′. Within about a minute of the S.C., H (horizontal force) was enhanced about 120γ. The appearance of the trace suggests a very rapid preliminary fall, but this is not clear. Immediately after the large rise a fall began in H, but the element remained above its normal value for about five hours. The disturbance following the S.C. was only moderate until nearly 20h. on May 13, when considerably larger movements appeared in H. Disturbance continued throughout May 14, but there was a comparative lull between 8h. and 16h. Subsequent, however, to 16h. disturbance became very active, and the night of May 14-15 was much more disturbed than the previous night.

The most disturbed period, on the whole, was from 0h. to 8h. on May 15. During this time the D trace was off the sheet three times, but only for a few minutes at a time, in the easterly direction, and twice on the margin or off the sheet in the westerly direction. The range actually shown was 2° 12′. In the course of an hour—4h. 25m. to 5h. 25m. on May 15—movements occurred of at least 108′ E., 107′ W., 94′ E., and 92′ W. Few, if any, of the larger D movements were absolutely unidirectional. The variations in the light intensity along the curve showed that superposed on the larger movements were incessant short-period oscillations. The H trace was similarly oscillatory, but it was beyond the limits of registration in the direction of H, diminishing from about 3h. to 7½h. on May 15; so the range shown, 650γ, was doubtless much exceeded.

In vertical force the disturbance was considerable on the night of May 13 between 21h. 45m. and midnight, but on the night of May 14–15 it was enormously greater. Assuming the scale-value to be unchanged since its last determination, the range reached 1500γ. Between 3h. 53m. and 4h. 10m. on May 15 there was a rise of 1400γ. A little later, in the course of twelve minutes, there were a fall and a rise each exceeding 950γ. These and other large movements had shorter period oscillations superposed on them. The abnormally disturbed state of vertical force lasted from 22h. on May 14 to 8h. on May 15. During most of this time the value was much depressed.

Disturbance continued over the whole of May 15 and 16 and until the early hours of May 17. There was a very highly disturbed time on May 16 between 2h. and 10h. The H trace was off the sheet for fully 1½ hours between 8h. and 10h. C. CHREE.

The Reparation Act and the Cost of German Publications.

MAY I direct attention, through the columns of NATURE, to the serious position of scientific institutions in this country in respect to the operation of the German Reparation (Recovery) Act, 1921? Under this Act, of the cost of goods imported from Germany, half is taken by the Government towards the German reparation indemnity. Of course, most objects of commerce imported from Germany can be made in this country, and perhaps the Act is partly designed to assist home industries. There are, however, certain chemicals which are not at present made with sufficient purity, but this can be corrected.

The serious point is that there are German publications which in no circumstances can be conceived as likely to be published in this country. The advance of science necessitates the study of these publications as soon as possible after issue. Booksellers and publishers in Germany with whom I have communicated have informed me that they cannot afford to sell them at less than the published price. To pay the published price I have to send my cheque for actually twice the published price, viz. to pay 100 per cent. extra.

I am now informed by the Board of Trade that a committee "have given consideration to the question of the exemption of German books and periodicals, but they have not felt themselves able to make any special recommendation regarding German publications." The matter seems to me to be serious, and one which might be profitably considered by the scientific world and the societies representing it in this country.

May 12.

Auroral Display.

A DISPLAY of the aurora borealis was observed from Pontypridd Common between 9.40 and 9.55 G.M.T. on Friday evening, May 13, the sky being quite clear of clouds.

The chief appearance was a single band of light, varying from 5° to 15° in breadth, and reaching from a little below Regulus, which appeared almost central in it, near the zenith, and thence to the horizon about east by north, where the view was limited by a hilltop with an altitude of about 15°. The band varied both in width and in intensity, the middle third of its length fading away and the ends alone remaining; then the middle grew bright again, the ends disappearing; then the full length reappeared and the whole faded away evenly. The band showed no colour and no flicker, only fairly rapid changes of intensity; its edges were undefined and its axis the most brilliant part. It was many times more brilliant than the Milky Way, and might be compared with the region of the sky round the moon as seen when the latter is hidden by holding up the hand. At the beginning there was a parallel band of similar appearance a few degrees to the south of the eastern third of the main band, and at one time when the ends were disconnected they no longer appeared to be in the same straight line. A. E. L. HUDSON.

The Colours of Primroses.

MAJOR LATHAM'S letter (NATURE, May 5, p. 301) on the coloration of primroses has attracted me, for I have been studying the genus for several years. For

use in my work I have accumulated a considerable collection of wild varieties of *Primula acaulis*, some of which have been kept merely for observation, whilst others have been used for experimental work in genetics, in the course of which facts having some bearing on the colour problem have emerged.

As was inevitable, I obtained the red-flowered form of the primrose very early, and soon noted its occurrence in restricted areas. In Northumberland and Durham I know it from only two wild stations, one on the coal measures of North Durham, and the other in a ravine on the slopes of Kilhope Law, at the head of West Allendale, in Northumberland. The latter is far above the levels of gardens, and nearly 800 ft. above the range of the cowslip, so that the possibility of hybridity is excluded. Nevertheless, all the plants bear red flowers.

With the view of testing how the red colour was inherited, several plants were transferred in spring, 1915, from an elevation of above 1500 ft. to our garden only 30 ft. above sea-level. Although these plants produced red flowers in their first season, just as their relatives did in their mountain home, I made no crosses that year, intending to let the plants establish themselves. To my amazement, however, in 1916, when they flowered, their colour was exactly that of the normal primrose, and as long as I kept the plants —until 1918—only normally coloured flowers appeared. On the other hand, plants brought from Kilhope Law to the Vicarage garden at Ninebanks (elevation just above 1000 ft.) showed no change whatever in flower colour.

From the above it is clear that the altitudes at which the plants grow have something to do with the problem, and that the actual agency may be the average temperature is indicated by the failure of some rose-coloured varieties of *Primula sinensis* to develop their proper colour unless a certain temperature is attained.

Further evidence, indicating that the same influence is at work, appears in the form of two other primroses in my possession brought from a height of 1200 ft. in Upper Teesdale. These bear yellow flowers much deeper in hue than usual, and, in addition, clothed with a dense vestiture of white hairs. As the cowslip ascends in Teesdale to the limestone of Harwood Dale (at 1600 ft.) hybridity is not excluded here, but against this is the fact that although I have examined hundreds of primrose-cowslip hybrids I have never encountered a plant in the least like these.

The insect to which Major Latham refers as the "primrose sprite" is no doubt *Bombylius major*, a fly often to be seen poised, with proboscis extended, over primroses in April. Aiding it in the work of pollination, but carrying on their operations in a more or less illicit fashion, are the thrips, *Taeniothrips primulae*, and larvæ of the Geometrid moth, *Larentia didymata*.

Earthworms Drowned in Puddles.

THE explanation suggested by Sir E. Ray Lankester (NATURE, May 12, p. 329) of the occurrence of dead earthworms in surface "puddles" described by Mr. Friend had occurred to me, viz. that they were drowned. As to the survival of such worms in cool, clear, running water for some time, it is well known to most "bottom" fishermen that worms will survive for a considerable time *on a hook* in such water, and it is conceivable that their ultimate death is due to a too free exchange between the body-fluid and the surrounding water at the wounds made by the hook rather than to inability to breathe.

I walk warily in dealing with zoological matters, but I may suggest that with the breathing apparatus described the "moist surface" must, when underground, frequently or usually be in contact with other moist surfaces, so that the worm is, in effect, partly immersed in water. The great advantage of breathing through the agency of a moist *film*, as the worm does when above ground and as mammals do, is that the exchanges between air and blood can take place very rapidly owing to the steep gradient of oxygen tension in the film. An animal normally living in water has to expend a great deal of energy in pumping water through its respiratory system in order to get enough oxygen to support life. Fish when in water very far from saturated with oxygen or saturated at a relatively high temperature are unable to get the water through their gills at a sufficient speed; in the latter case the temperature coefficient of vital activity is against them, as they live faster at higher temperatures.

The oxygen dissolved in water is very small in amount. At 15° C. it is about 7 c.c. per litre, or one part by weight in 100,000. The oxidisable matter in moderately contaminated water will consume about 0·2 to 0·4 part of oxygen in five days at 18° F. (Adeney's test). The consumption of oxygen would naturally be relatively rapid in the early stages. Rain-water is approximately saturated with oxygen, but the considerable mass of oxidisable matters in dead and rotting leaves might easily take up the dissolved oxygen much more rapidly than re-absorption could take place in a stagnant pool of appreciable depth. If so, the worms which might manage to keep going for a time in well-aerated water, although with difficulty, would die in water which did not continually provide a surface layer fully saturated with oxygen in contact with their skin.

I hope to be able to make some quantitative investigation of the matter.

The Physical Continuity of "Space."

IN the "space-æther" discussion clarity is lost by a failure to distinguish between "container" and "content." The relativist does not assert that there is no content. He is concerned with the geometry of the container; if this geometry assists the metaphysician or philosopher to a better understanding of the content, he is satisfied. If the container is called the world-frame (a term free from the ambiguity of æther), the relativist maintains that its geometry is four-dimensional and hyperbolic (semi-Euclidean) in character so long as the content is free from the influence of energy. This may be a condition of absolute rest or it may not. When the content is disturbed and energy manifested, the world-frame geometry is altered, and the world-frame may then be better described as the world-fabric.

Einstein relates the intensity of disturbance to the change in the geometry of the fabric with respect to that of the frame. He does not concern himself with the content of the frame, but only with that content of the fabric which manifests itself as free or bound energy. He leaves it to the metaphysician to deduce

that the content of the frame is the content of the fabric in absolute rest, or to make any other deduction he logically can. He does not pretend to explain what energy is or what it may become if reduced to absolute rest. He does not assert that there is no absolute rest, but that it escapes his and all experience.

The Production of Metallic Zinc.

In the issue of Nature for April 28 I observe under "Notes" (p. 279) a reference to the small volume on zinc recently issued by the Imperial Mineral Resources Bureau. In this reference it is pointed out that the figures relative to the production of metallic zinc in the United Kingdom for 1913 do not harmonise with the figures of production and imports of zinc-ore. Naturally so, for there are other factors involved in the production of metallic zinc in any given year. The output of metallic zinc is not necessarily derived entirely from the ores produced at home or imported in that particular year; the part played by "secondary" production—that is, metal obtained from hard zinc—is of importance in this connection.

As regards the use of the expression "long ton," to which the writer of the note objects, preferring the words "statute ton," it has been made abundantly clear in the prefaces to the Bureau's publications that "the weights are expressed in long tons—that is to say, the British statute ton of 2240 lb." The ton of 2240 lb., though the "statute" ton in the United Kingdom, is not necessarily the "statute" ton in other countries. The expression "long ton" has not only the advantage of conciseness, but it is also well understood throughout the mining and metallurgical world.

R. A. S. Redmayne,
Chairman of the Imperial Mineral Resources Bureau.

2 Queen Anne's Gate Buildings,
Westminster, London, S.W.1.
May 4.

Sir Richard Redmayne puts forward two explanations to account for the discrepancy in the statistics published by the Imperial Mineral Resources Bureau. The first of these, namely, that stocks of ore may be carried over from year to year, is, in view of the relatively small differences from year to year, inadequate to account for the great discrepancy noted. The second is, in fact, the true explanation. Secondary zinc accounts for about one-half of the so-called zinc output of the country, and thus seriously affects the statistics.

The Writer of the Note.

The Theory of Vision.

Prof. Joly's papers on vision are very interesting. He adopts the visual purple as the visual substance, but there is no evidence that the rods are percipient elements. The view that they are percipient elements is based on errors, as, for instance, that certain animals—the tortoise is the most quoted—possess only cones; that the periphery of the retina is colour-blind; and that the Purkinje phenomenon is not found with the fovea. The tortoise has the rods and cones as definitely marked and distinct from each other as in man. Has any reader seen a retina in which there are only rods or only cones in any animal? The periphery of the retina is not colour-blind. Red of sufficient luminosity can be seen to the extreme periphery. The Purkinje phenomenon is found with the fovea, and is a photochemical phenomenon. It is very improbable that the rods are percipient elements. An elaborate nervous mechanism is required to regulate the sensitiveness of the photochemical film, and this appears to be the function of the rods.

The stimulus in vision is undoubtedly liquid, as shown by the movement of positive after-images.

The decomposition of the visual purple stimulates the ends of the cones. The ends of the cones consist of a series of discs varying in diameter.

A New British Land Planarian.

Mr. Morison's discovery of the interesting planarian worm (*Rhynchodemus Scharffi*) in a garden at Chiswick, as described in Prof. Dendy's letter in Nature of May 5 (p. 298), shows that this species has a wider range than was at first anticipated. As Prof. Dendy states, it was first discovered in a Dublin garden in 1894, but since that date it has turned up in the Royal Botanic Gardens at Glasnevin, Dublin. I thought it had probably been introduced into both localities, but that nevertheless it was indigenous to Ireland.

It seemed to me most likely to have been brought from the country with a load of turf. This view was confirmed when, in April, 1901, I found several specimens of this planarian worm in the open country under a fallen tree-trunk near Ballymote, Co. Sligo (see *Irish Naturalist*, vol. x., 1901, p. 133).

Cutting Sections of Cotton Hairs.

In our laboratory we have now, for some months, utilised Mr. H. J. Denham's plan for celloidin-paraffin embedding of the cotton hairs, on the lines of Kultschitzky's and other processes (Worden: "The Nitro-cellulose Industry," p. 805), described in Nature of May 5, p. 299, which Mr. Denham kindly communicated to us when he first suggested it, and we have found it most satisfactory. We immerse the hairs in dilute celloidin, which is then boiled down to a syrup (Gilson's process); the hairs are next transferred to paraffin-chloroform, and thence to 60° C. paraffin (Ide's process); this makes a very rapid technique, cut sections being available within two hours. We have also tried the method of Willows and Alexander, but find it cytologically inferior to this celloidin-paraffin technique, which gives us excellent sections at $2{\cdot}5\mu$ setting on a Leitz sliding microtome, with accidental sections even thinner.

British Scientific Instruments.

In the review of the "Dictionary of British Scientific Instruments" published in Nature of May 12, p. 324, it is stated that the British Optical Instrument Manu-

facturers' Association, which has issued the dictionary, "is one of the industrial associations working in connection with the Department of Scientific and Industrial Research." Will you permit me to correct a slight misunderstanding here? The British Optical Instrument Manufacturers' Association is a trade association, and is independent of the Department of Scientific and Industrial Research. The industrial research association formed under the scheme of the Privy Council for the promotion of scientific and industrial research is the British Scientific Instrument Research Association. Most of the leading British manufacturers of scientific instruments are members of both associations, but the credit of publishing the dictionary referred to is due wholly to the British Optical Instrument Manufacturers' Association.

J. W. WILLIAMSON,
Secretary, British Scientific Instrument Research Association.

Picture-hanging Wire.

I SHOULD be glad to know the best kind of wire and the best form in which to use it for hanging pictures, etc., on walls.

Some ten years or so ago I was advised to use twisted brass wire of five strands, which was then immensely strong with a breaking strain of probably more than 100 lb., but it has become so rotten as to break under a weight of a pound or two. This wire has been in use in a very dry room with electric light only. My own experience has proved that plain copper wire in one strand has lasted three times as long as the twisted brass wire, though bearing far heavier weights. Before the war a "wire" consisting of a steel core with some other wire braided over it was recommended, but it is soon affected by rust, and appears to be much stronger than it really is.

The Occurrence of Bombus in the Indian Plains.

As it is generally agreed among naturalists that the genus Bombus—the "bumble-bees" of Europe—is in India entirely confined to the hills, and never descends below 3000 ft., I write to record its occurrence in the plains.

Nearly three years ago, when my entomological knowledge was yet in a rudimentary state, I remember occasionally seeing a bee, which I considered a species of Bombus, at Sukna, situated at the base of the hills of the eastern Himalayas. The few friends to whom I mentioned the incident generally politely turned the conversation aside, but the actual capture a few days ago in Calcutta of two specimens of *Bombus tunicatus* seems to indicate that my first observation was probably correct, and that "bumble-bees" do (very rarely, of course) occur in the Indian plains in the cold season.

Symbols in Vector Analysis.

IN books on mathematics and physics where vector analysis is used it is customary to use clarendon or thick-letter type to distinguish vector from scalar quantities. This practice has, among others, the disadvantages that it reduces the number of symbols available for other purposes, and is impossible to reproduce in manuscript.

It is justified only by the fact that it prevents confusion between the two types of quantities and the consequent application of algebraic operations to vector quantities and *vice versa*.

Another means of reaching the same results without the above disadvantages would be to replace the symbols $+$, $-$, and $=$ by new symbols in vector analysis. This would be of itself sufficient to differentiate vector from algebraic symbols, and would be more logical, as the symbols stand for quite different ideas in the two systems of analysis.

Young's Interference Experiment.

I HAVE read with considerable interest Dr. Houstoun's letter on Young's experiment in NATURE of April 28, p. 268, and I beg to state that we have been using the spectrometer for some time in the University College of Science, Calcutta. For making the double slit, a rectangular slit, about 2 cm. × 2 mm., is cut in a piece of cardboard. Two Gillette razor-blades are placed on two sides of this slit by small pieces of wax. At the centre a fine cocoon fibre, or preferably a spider thread, forms a double slit. By mounting the cardboard on the prism-table the fringes are easily seen, and as the rotation of the table alters the width of the slit the change in the nature of the fringes can be easily examined.

The Origin of "Churning at 62°" on Dairy Thermometers.

MR. HEDGER WALLACE's question (NATURE, April 28, p. 268), "Why do makers of dairy thermometers mark their thermometers 62° F. as churning temperature?" interests us as thermometer-makers who are frequently asked to supply floating dairy thermometers to a particular pattern. In many cases the customer decides the pattern, and we are prepared to satisfy our customers' requirements. We make and sell a large number of dairy thermometers not marked at any particular temperature for churning, and we advise this pattern, as we are told by dairy experts that any temperature between 45° and 62° F. may be required, according to conditions. It appears that no definite temperature can be fixed; therefore, to mark 56° F. as a fixed point for churning would be equally in error.

Organism in Flint.

IN reference to Prof. Cole's suggestion (NATURE, May 12, p. 333), the possibility of the organism being a radiolarian was considered long ago and rejected. The consensus of opinion is now in favour of its being a beetle. Under higher powers the clavate and merismatic antennæ are very conspicuous. There is no micro-slide of the fossil; the photographs are taken direct from the flint-surface. Special photographs of the organism's separate parts are now being prepared under more favourable conditions, and will be available shortly.

Direction-finding Wireless and Marine Navigation.

By J. J. BENNETT.

THE use of wireless telegraphy for direction-finding purposes, which came into vogue in the Navy during the war, seems likely to remain as a permanent auxiliary to sea navigation. France, the United States, and Canada have each adopted the system, and it is understood that Germany is maintaining some of the stations which she erected for war purposes, although definite information on the subject is lacking. So far as Great Britain is concerned, the Admiralty has established direction-finding wireless stations at the Lizard and at Carnsore Point; and it is also continuing for the present the stations at Berwick and Flamborough. Although a nominal fee of only five shillings is charged for giving a vessel a bearing by wireless, our merchant service does not appear so ready to take advantage of this assistance as it was anticipated it would be. This attitude of indifference is probably due to the value of the system not being understood sufficiently. Nevertheless, direction-finding wireless has proved of great help to the seaman on many occasions, and, beyond all doubt, will grow in favour as the mercantile marine becomes more familiar with its working.

The principal use of the system is to enable the bearing of a vessel in open waters, or when approaching pilotage waters, to be determined from one or more fixed points by intersection. All bearings thus obtained are the Great Circle bearings at the place of observation, which may be on shore or aboard ship, according to the method employed. If proper care be exercised, the average of error will be very small—less than one degree. Experience has shown that day readings over water are always trustworthy, and, unless high land is close to the vessel, day readings over land are approximately accurate. Night readings over water are approximately correct at short ranges of about one hundred miles; but night readings over land and over long distances are liable to error. Sunrise and sunset times should both be avoided, as bearings then obtained by wireless cannot be relied upon for accuracy.

There are at least three methods of using directional wireless to give ships their bearings and position. One requires no special apparatus in the ship, the others do. In the case of the first-mentioned, any vessel fitted with wireless telegraphy can call up a shore station and ask for a bearing. The station signals back that it is ready to give the bearing; then the vessel makes her call sign continuously for a short period, during which time the shore station ascertains the bearing by means of its direction-finder, or radiogoniometer, and then transmits to the vessel her true bearing with the time at which it was observed. Responsibility for accuracy rests, in this instance, upon the station. If the vessel requires simultaneous bearings from two stations in order to obtain her position, she calls up the controlling station of the shore group and states her need. Both stations then determine simultaneously by their direction-finders the respective bearings of the vessel; the controlling station collects both bearings, and either transmits them to the vessel, with the time at which they were determined, or, if equipped with the necessary instruments for the purpose, the station fixes the position of the vessel as obtained from the bearings and sends the information to the vessel. The main disadvantage of this method is that only one ship at a time is able to call up a station. If more than one tried to do so, "jamming" might result. Further, the distance over which bearings can be obtained is limited to one well within the maximum range of the ship's installation. If the bearing only is transmitted, the ship must be furnished with special charts or special tables of correction, as the bearings obtained are the Great Circle bearings at the shore station.

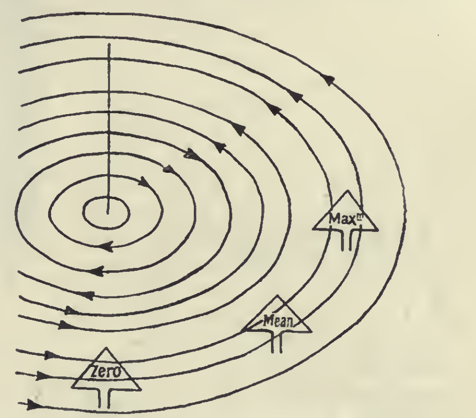

FIG. 1.—Field of magnetic lines of force through a loop aerial. This aerial may be regarded as inductive to the field of magnetic force of the advancing waves in certain positions, but as non-inductive in certain other positions. In the figure, for the sake of simplicity in drawing, it is assumed that the loop is being moved round the transmitting station so that its plane is pointing at the station at the right hand or maximum current position, and is facing the transmitter at the lower or zero current position.

As to the station itself, it must have a direction-finding plant, as well as an ordinary wireless transmitting installation. The plant consists of wireless direction-finder set, tuning apparatus, receiving and amplifying set with accumulator batteries, dry batteries, etc., and a small power plant for charging purposes. Where two or more stations are grouped together for co-ordinate direction-finding work, the controlling one may be equipped with wireless transmitting apparatus, the others with direction-finding apparatus only, and be connected with the master station by telegraph or land telephone. Any ordinary shore transmitting station is suitable for undertaking communication with ships requiring bearings, so

that, as an alternative, two or more direction-finding stations of a group covering a certain area may be equipped with receiving gear only, and an ordinary separate transmitting and receiving station may undertake the controlling duty. A station may be self-contained. In such case the aerials for the direction-finding receiver and for the transmitter must be spaced a short distance apart, whilst the receiving and the transmitting apparatus must be housed in separate buildings, the whole of the receiving being done on the direction-finding receiving apparatus, and the transmitting apparatus being operated electrically from the direction-finding room.

A ship equipped with directional wireless apparatus can obtain bearings from any known ordinary wireless telegraphy shore station; but it is preferable that certain of these stations should be detailed to transmit, simultaneously or successively, signals on given wave-lengths at definite times during each hour. This is known as the Beacon Station method. Only vessels fitted with direction-finding apparatus are able to use it. The apparatus comprises a twin direction-finding aerial system consisting of either suspended fixed wires or large rigid frames, together with wireless direction-finder, tuning apparatus, and receiving and amplifying gear, with batteries and charging plant. A cabinet for the apparatus and operator, and telephone or buzzer communication with the ship's steering position, are also necessary. Such an installation costs about 300*l.*, apart from the expense of fitting it. Any number of ships can obtain bearings, or fix their position, at the same time from the same station by this method, and are able to do that over much longer ranges than is the case with the method first described. As, however, ships using their own direction-finding sets are responsible for the accuracy of the bearings obtained by them, their staffs require some technical skill in the work, and it is necessary that the instruments should be calibrated and checked occasionally.

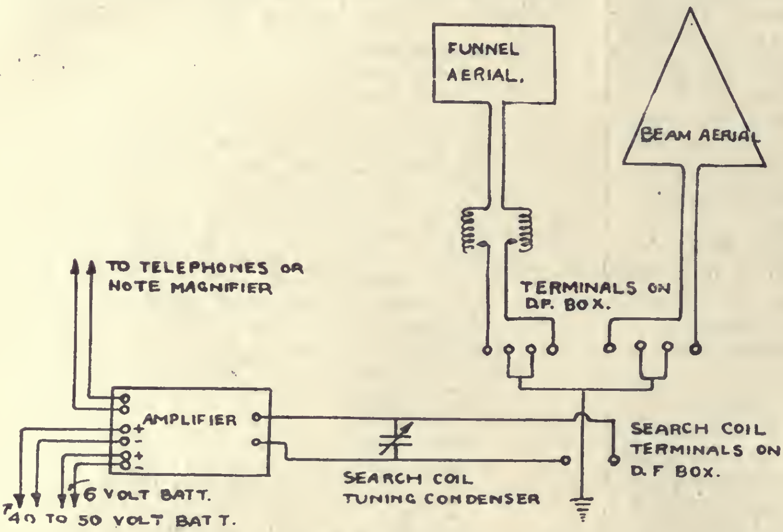

FIG. 2.—Simple circuit for aperiodic aerial and spark reception aboard ship. The beam aerial is rigged in the thwartship line so that it receives no induced signals from the ship. The funnel, or fore-and-aft, aerial receives signals direct *plus* induced signals from the ship. If the two aerials are adjusted to an equal sensitivity, they will always produce a resultant field in the direction-finding transformer in the same line as the incoming wireless wave, and the bearings obtained will be correct.

In the third method a rotating directional wireless beam having a fixed angular velocity is transmitted by a specially fitted fixed transmitting station. The rotating beam has a sharply defined zero direction which passes through North and South at given times. Knowing the angular velocity of the beam, and by observing the time interval between the given times at which the zero passes through North and South and the time at which the zero signals are received in the ship, the bearing of the station can be determined.

In order to ensure that the watches in the transmitting station and the receiving ship are synchronised, the station transmits a timing signal before commencing the rotating beam. To use this method, a ship must carry on her bridge a special watch, the face of which is marked in degrees, the scale corresponding to the angular velocity of the rotating beam. If this watch is started at the moment indicated by the timing signal, the bearing in degrees of the ship from the station can be noted from the watch at the moment when zero signals are received, and this bearing can be checked with subsequent zeros. During the war Germany had three stations working by this method, but Great Britain has none.

Aboard ship the simplest form of direction-finding apparatus is a single-loop aerial rotated round its vertical axis through a horizontal scale. To increase the current through the loop, it is usual to tune the loop with a condenser to the wave-lengths required to be received, and instead of a single loop a frame fitted with a multi-turn loop may be used. In the Bellini-Tosi system, in place of a rotating loop aerial two fixed loop aerials are employed, these being connected to an instrument known as the radiogoniometer, or direction-finder transformer. Inside the latter is a small revolving coil attached to a pointer moving over a scale by which the direction of the signals can be determined. Since, however, the receptive powers of a comparatively small loop aerial, such as can be employed in direction-finding aboard ship, are very much inferior to those of the ordinary type of ship or shore station earthed aerial, a signal-amplifying apparatus employing several vacuum valves is an essential feature of the direction-finding receiver.

Cloud Forms.[1]

By CAPT. C. J. P. CAVE.

MOST writers on clouds put forward their own system of classification, much to the confusion of the subject; Mr. G. A. Clarke is therefore to be congratulated on adhering to the international classification in his recently published book. He says that even to divide the recognised types into sub-types makes the classification unwieldy, and is open to the objection that, "particularly in the case of the cirrus . . . one sub-type may be transformed into another and then perhaps return to its original form all within the space of a few minutes." He even suggests that any change should rather be in the direction of further simplification. In chap. ii. the international classification is given in full, so that for English readers Mr. Clarke's book may well supersede the Cloud Atlas, for the former contains all the essentials to be found in the text of the latter, and the illustrations cannot for a moment be compared. Where the atlas gives a few illustrations, some very indifferent, of each type, Mr. Clarke gives numerous examples that for variety, wealth of detail, and excellence of production easily surpass previous pictures.

There are many plates of cirrus and cirro-cumulus, some giving details of structure, and some whole skyscapes of these the most beautiful of all the forms of clouds. Very noticeable is the plate of cirro-stratus, "a thin whitish sheet of clouds," and therefore very difficult to depict satisfactorily. Mr. Clarke has carefully studied lenticular clouds and gives many examples, while in the text will be found a discussion of these extremely interesting and hitherto rather neglected forms of cloud; an example, perhaps the most striking photograph in the book, shows such a cloud with its front edge lit up by the setting sun, while part of its under surface, also in sunshine, is broken up by a double set of ripple marks (Fig. 1). There is no doubt that the cloud sheets have been rendered by Mr. Clarke better than has been done in any previous publication; but some of the photographs of cumulus leave something to be desired, chiefly owing to the use of a lens of too narrow an angle for the size of the clouds; pictures of cumulus gain in effect if the main cloud does not fill up the whole of the picture. The most remarkable plate in the whole book from a photographer's point of view is that which shows a rainbow on the shower from the base of a cumulo-nimbus cloud (Fig. 2); to show a rainbow, three super-

FIG. 1.—Lenticular cirro-cumulus at sunset. From "Clouds."

FIG. 2.—Rainbow on screen of rain falling in middle distance. From "Clouds."

[1] "Clouds." By G. A. Clarke. Pp. xvi+136+40 plates. (London: Constable and Co., Ltd., 1920.) 21s. net.

numerary bows, a secondary bow, and the lighter space inside the primary bow requires a photographic technique of a high order. It is with regret that we miss a chapter on cloud photography from the hand of such a master. Everyone has a slightly different technique, but Mr. Clarke unfortunately gives no hint of his own methods. The series of plates ends with some fine photographs taken by Capt. C. K. M. Douglas from an aeroplane.

There are also several coloured plates and drawings; the frontispiece is a delightful coloured sketch of a beam of a searchlight revealing two layers of fine condensation before striking the main cloud sheet; it vividly recalls a phenomenon which must have been noticed by many meteorologists during the war. Another very beautiful plate shows a halo, sun pillar, mock sun ring, and two arcs of contact. The four sketches showing stages in the history of a line squall cloud are interesting as diagrams, but as pictures they make the clouds look too solid.

If more notice has been taken of the plates than of the text, it is because they form the most striking part of the book; but the text contains much interesting matter. Cloud forms are described, and use is made of recent researches into upper-air temperatures in explaining cloud phenomena. There are chapters on cloud distribution, and the association of cloud forms with weather types. Mr. Clarke has produced a standard book on cloud forms, not only for the meteorologist, but also for the general reader, who will surely find it an incentive to a further study of the weather. Author and publishers are to be congratulated on the excellence of the work.

Unveiling the Senussi Shrines.

By ARTHUR SILVA WHITE.

THE story of Mrs. Rosita Forbes's journey to the oasis of Kufra, situated in the heart of the Libyan Desert, constitutes the "something new out of Africa" of which few vestiges remain to be revealed. The three instalments recently published by the *Times*, under the title of "Secrets of the Sahara," contained the latest, and in some respects the only, information from a locality in the Libyan Desert unexplored since the visit of Gerhard Rohlfs in 1879.

Rohlfs made two attempts to reach Kufra. On the first he was turned back (although travelling under the protection of a *firman ali* of the Sultan of Turkey) from Aujila and Jalo because the Mojabra (slave traders) refused to give him a guide without Senussi's consent; and on the second attempt, when he succeeded in reaching Kufra, he was made captive and barely escaped with his life. Where Gerhard Rohlfs failed, and found no European successor for forty years, Mrs. Forbes has succeeded; but, it is to be noted, the reason for this remarkable achievement is to some extent explained by the total change of circumstances. In the interval between the two adventures, the Great War has resulted in the military conquests of France and Britain in that region of Africa and in the overthrow of the Senussi domination. Moreover, Mrs. Forbes had the supreme advantage of entering Libya at the psychological moment of complete accord (the ratification of a treaty) between Italy and the Grand Master of the Senussi Confraternity, whose personal support she obtained, and of travelling, not as a European, but as a Moslem in the interests of Islam—that is to say, practically as a Moslem convert or Senussi propagandist, since the Senussi commonly employ women in that capacity. That Mrs. Forbes could have kept up this disguise through all the vicissitudes of travel and the dangers encountered is in itself one of the stories out of Africa which deserve to be remembered.

Mrs. Forbes, accompanied by Ahmed Bey Hassanein, an Egyptian (son of Sheikh Mahamed Hassanein el Bulaki, a professor at El Azhar University), started from Benghazi, the maritime terminus of the ancient trans-Saharan caravan route, and rode eighty miles south to Jedabia, where the desert journey began. Here she was hospitably received by Sidi Rida (brother of Sidi Idriss, the Sheikh es-Senussi or Grand Master), who made himself responsible for her caravan. But the usual delays, leading to divided counsels among the Senussi brethren (Khuan), necessitated a midnight flight in Bedwin disguise without a guide. After wandering round Jedabia for three hours, the fugitives found themselves only one mile away in the open desert when day dawned. Riding south for two days, accompanied by two trusted Senussi, they were joined by two black soldiers unprovided with rations. The party, numbering six, were saved from starvation by meeting with a Mojabra caravan, and together they travelled by short stages to the oasis of Aujila. Here they were caught up by the caravan prepared by Sidi Rida, who sent also a letter of introduction to the Kaimakam at Jalo, near by, the gate of the Libyan Desert.

The caravan, now fully organised, comprised eighteen camels, nine black servants, two slave-girls, a guide (Abdulla el Zawia), three Bedwin, Ahmed Bey Hassanein, and Sitt Khadija—"a Moslem of half English, half Egyptian blood"—otherwise Mrs. Rosita Forbes. For so large a party eighteen camels were far from adequate, especially as these were in bad condition, for a

journey in the Libyan Desert. Consequently, from the very outset privations overtook the party.

The first stretch across the desert, from Bir Battifal to the oasis of Taiserbo (which was passed unheeded), with no wells on the route, was accomplished with ever-increasing difficulties, owing apparently to the failure of the guide to pick up his landmarks and the consequent delays. It took nine days to reach El Harrash, where water was found, and two days more to reach Buzeima. Here, after the fatigues and sufferings of the march, a halt of three nights was called to rest the caravan. Four days onwards, passing through a region of sand-dunes, they came to Hawari, on the outskirts of Kufra oasis. Taj, the objective of their pilgrimage, lay more than twelve miles further south.

Intrigues and plots had to be faced and overcome before the guests of the Sheikh es-Senussi were allowed to continue their journey; and no wonder! Indeed, there must be a sharper cleavage than ever before between the more rigid Senussi of the banished Grand Master, Sayed Ahmed, who was answerable for the war against Egypt and the Nosrani (Christians), and the post-war adherents of the ruling Sheikh, Idriss, who, according to the doctrine of their Order, must be regarded as a renegade Senussi. In the precincts of the sacred city, Taj, our suspect travellers were on dangerous ground.

The Kaimakam of Taj, Sidi Saleh el Baskeri, after due inspection of their credentials, received the travellers well, and lodged Mrs. Forbes in the house of Sidi Idriss. In the home of the Sheikh es-Senussi this courageous young Englishwoman "lived the life," as she says, "of a veiled Arab woman of Taj for nine days, and visited the holy *Kubba* of Sidi el Mahdi," the son and successor of the founder of the confraternity. Of course, she was under suspicion, and fifteen tribal Sheikhs offered objection to her wandering abroad, since such a privilege is unknown to Arab women and the women of Taj. Nevertheless, a flying visit under the official auspices of the Kaimakam (presumably the Turkish Resident) was made to the west, a ride of seventeen hours, providing some interesting sight-seeing of which we may hope to hear later.

When the time came for her departure from Taj, Mrs. Forbes decided "to attempt to open up a new route to the north, hoping to facilitate future trade with Egypt." The route she selected and afterwards followed appears, however, to have been one of the direct routes (Kufra to Jarabub, Kufra to Siwa, and Kufra to Khargeh) reported to have been opened up by the Senussi, after their settlement at Jalo and Jof. These routes, as also that from Siwa to Farafra oasis, were at one time kept open for the use of all followers of the Prophet, so that even single travellers might use them and find refuge at the end of each day's march—at least, that was the boast of the Senussi, who undoubtedly did make settlements for so-called slaves, and built cisterns along some new routes in the Sahara. Apparently, then, the direct route between Kufra and Jarabub, selected by Mrs. Forbes, fell into disuse (if used only by the Senussi family) in consequence of the absence of Sheikh el Senussi at the seat of war. That is my conjecture.

The homeward journey, starting from Hawari, was begun on January 25, 1921. Previously, Mrs. Forbes had sent back the soldier slaves and others to Jalo and Jedabia, and her new caravan for this hazardous journey to Jarabub comprised only nine camels. Besides herself and Ahmed Bey Hassanein, the party consisted of Yusuf, a Zawia student named Amar, and the guide Suleiman, an oldish man with defective eyesight. Zakar, a well that had not been used for four years, and, therefore, had to be cleared, was reached in four days; and from that spot onwards no well or cistern was available during the twelve days' march through the arid desert to the outlying parts of Jarabub. They carried twelve skins of water, dates for the camels, fuel, but no tents. Marching for thirteen hours daily, averaging thirty miles a day—presumably at night, to make such good progress—they endured great hardship on a simple and scanty diet. Sand-dunes both at the beginning and at the end of their journey were encountered. On the eleventh day from Zakar they entered broken country beyond the dunes, and stumbled upon Bir Salama (?Tarfaja), on the Jalo-Jarabub caravan route. Thence to Jarabub was but a day's march.

At Jarabub—the Mecca of the Senussi—which never before had been entered by a European, Mrs. Forbes was lodged inside the Zawia in a house belonging to the Khuan (brethren), and she was even permitted to kiss the tomb of the sainted founder and to visit the University quarter.

On February 13 the journey was resumed, and, with four camels and a guide, Mrs. Forbes came joyfully to Siwa under the escort of a Camel Corps patrol sent out to meet her. Thence, after a cordial reception from the officers at Siwa, she motored (new style) across the desert for 430 miles to Alexandria.

This bare recital of Mrs. Forbes's remarkable journey raises in the mind of one who knows something of the country and of the Senussi confraternity profound admiration for the woman who accomplished it; and further details of her experiences will be eagerly awaited. The information she brings from Kufra and Jarabub, in particular, will appeal to geographers, who will not be too critical as to her revision of the map unless other instruments than a magnetic compass were used by her. In addition, any information about the Senussi sect will prove of the highest interest, in view of the fundamental changes in their doctrine and policy superinduced by their defeat in the field under Turko-German leadership.

Obituary.

Prof. H. W. G. von Waldeyer.

THE years of the war were disastrous to German anatomy, the deaths of men like Gaupp and Brodmann, Bütschli and Edinger, to mention only four, leaving gaps which have not been filled. But on January 23 of this year the Nestor of German anatomy, Geheimrath Heinrich Wilhelm Gottfried von Waldeyer-Hartz, died in the eighty-fifth year of his age, a month after Austria had lost one of her leading anatomists, Prof. Holl, of Gratz. Waldeyer was a man of genial and commanding personality, who, from the time he became professor of anatomy in Berlin in 1883, had been the recognised leader of German anatomists and biologists, and their spokesman at home and abroad. Even in his old age he was tireless in his attendance at congresses and scientific meetings, and undertook long journeys to all parts of Europe and poured forth fluent orations in sonorous and easy periods. But, apart from his gifts as an orator and congressman, Waldeyer had an exceptionally wide knowledge of anatomy, histology, embryology, pathological anatomy, and anthropology, in each of which he was regarded as an expert who could speak from a personal acquaintance with the facts.

Born on October 1, 1836, Waldeyer did not proceed to his doctorate until 1861, when he submitted to the Faculty in Berlin a dissertation "De claviculæ articulis et functione"; for when he entered the University of Göttingen he devoted himself to pure science, and then, from 1856 to 1858, to physiology and pathological anatomy. But during those years he came under the influence of the great Göttingen anatomist Henle, who was responsible for giving Waldeyer an aim in life and the inspiration to follow it. The next three years he spent as assistant to the anatomist Budge; then as an assistant for two years in the physiological institute at Königsberg, and for another year in a similar position under R. Heidenhain at Breslau, where in 1865 he was made extraordinary professor of pathological anatomy, and two years later an ordinary professor of the same subject. He held this position until 1872, and so great was the reputation he established as a pathologist that fifteen years after he had given up pathological for normal anatomy he was called to the bedside of the Emperor Frederick at San Remo as an impartial witness to settle the dispute which had arisen between the surgeons, British and German, as to the nature of the laryngeal growth from which the penultimate Kaiser was suffering. During the long tenure of his chair of pathology Waldeyer did not neglect his chief interest, normal anatomy and embryology; for during this period he wrote his famous work "Ueber Eierstock und Ei," illustrations from which have ever since been in every textbook of anatomy, histology, and embryology.

In 1872 Waldeyer for the first time was given charge of a department of anatomy: it was a position of quite exceptional difficulty and delicacy in the new school which the Prussians built up in Strassburg after wresting it from the French. Here Waldeyer displayed his remarkable abilities as a tactful administrator and peace-maker. So successful was he in this formidable task that in 1883, when the Prussian Government had another difficult problem to solve, to find a successor to the senile Reichert in Berlin, Waldeyer was appointed, although Koelliker, Gegenbaur, and His were senior to him and had a greater prestige as anatomists. Waldeyer had a very difficult task to reduce to order the chaos bequeathed to him by Reichert; but he set to work to build up a great institute, not merely of gross anatomy, but also of histology and embryology. Five years later he was able to secure the establishment of a second professorship of anatomy, to which O. Hertwig was appointed, to relieve Waldeyer of part of the work in histology and the whole of embryology. Waldeyer relinquished his position only about three years ago. In Berlin he came to be regarded as the father of German anthropology after the death of Virchow. He succeeded Max Schultze as editor of the *Archiv für mikroscopische Anatomie;* after His's death he became editor of the anatomical part of the *Archiv für Anatomie und Physiologie,* and after Virchow's death editor of the *Jahresbericht für die gesamte Medizin.* He also succeeded Du Bois-Reymond as the secretary of the Berlin Academy of Sciences, and was made a member of the Prussian Herrenhaus.

In spite of this overwhelming programme of disturbing engagements, and his ubiquitous presence and active participation in congresses at home and abroad, Waldeyer continued his work of original investigation, and published an unbroken stream of memoirs ranging over the whole of anatomy, histology, embryology, and anthropology. Almost every domain of anatomy that he invaded, whether it was the structure of fibrous tissue or bone, the development of teeth, the morphology of the reproductive organs, the comparative anatomy of hair, or the interpretation of the central nervous system, he reduced to order, and left some clarifying conception, and as a rule some new term, to clear away difficulties of interpretation. His work is so voluminous and many-sided that it is impossible to review it concisely. But his well-known efforts to clear up confusion on the subject of karyokinesis, and his attempt in 1891 to dissipate the chaos of interpretation of nervous structure by inventing the term *neurone* (Greek νεῦρον—German Neurōn—*anglice* neurone), are typical of Waldeyer's *métier.* If he was not a brilliant genius, he was a man of calm judgment and exceptionally clear insight. It was these qualities that made him so great a power in the modern

history of anatomy and the author of so many clarifying expressions of what other people were trying in vain to set forth.

As a lucid exponent and as a teacher he was pre-eminent. Many young anatomists have had occasion to appreciate his fairness and his weighty help in defending themselves from attacks even from his own countrymen. With his death there passes away perhaps the most influential anatomist of modern times. G. Elliot Smith.

Notes.

The large group of sun-spots which became visible a few days ago has been accompanied by disturbances of the magnetic and electrical conditions of the earth, manifested by magnetic storms, interruptions of the telephone and telegraph services over the greater part of the world. and brilliant auroral displays. Large sun-spots often appear without producing any such terrestrial effects, and magnetic storms sometimes occur in the absence of sun-spots, so that the relationship between the two phenomena is obviously exceptionable. There is evidence that solar prominences are more closely related to the production of magnetic disturbances on the earth than are sun-spots, which are only visible effects of solar disturbances the exact nature of which remains to be discovered.

That wireless telephony is fast emerging from the experimental stage into that of practical utility is evidenced by the interesting demonstrations, in which the *Times* participated last week, between stations equipped by the Marconi Co. at Southwold, in Suffolk, and Zaandvoort, in Holland. There is no technical reason why these stations should not be linked up with the ordinary telephone systems of Great Britain and Holland, so that it would be possible to communicate freely between any point in either country to any point in the other. It is interesting to note that the stations work on the short wave-length of 100 metres, which makes them free from interference from the 600-metre wave commonly used for marine communication and from the higher wave-lengths of the long-distance stations, as well as less likely to be influenced by stray disturbances than if a longer wave-length were employed. Other methods of protection against interference are being experimented with, and also of securing a greater degree of directive effect instead of broadcast emission, which, when such stations multiply, should contribute very materially to freedom from mutual interference. It is not generally known that wireless telephony is already employed by the Stock Exchange in Amsterdam for communicating prices to points all over Holland, and that these messages can be picked up in this country without difficulty. Dr. J. A. Fleming, the pioneer in the applications of the thermionic tube, upon which so much of the advance in wireless telephony is due, points out, in an interview in the *Times*, the great possibilities as well as the great achievements of wireless telephony, and emphasises its advantages over line-working in that no distortion of the wave is produced; as, in the case of wireless, all the harmonics are attenuated in the same proportion as the fundamental, because they are all propagated at the same rate.

The annual visitation of the Royal Observatory, Greenwich, will be held on Saturday, June 4. The observatory will be open at 3.30 for inspection by invited guests.

Prof. John Merle Coulter, of Chicago, Dr. Samuel Garman, Prof. Giovanni Battista Grassi, of Rome, Prof. Louis Alexandre Mangin, of Paris, and Prof. Jean Massart, of Brussels, have been elected foreign members of the Linnean Society of London.

At the anniversary dinner of the Royal Geographical Society, to be held at the Connaught Rooms at 7.30 p.m. on Tuesday, May 31, the guests will include the French Ambassador, General Bourgeois, Earl Beatty, Earl Buxton, Viscount Chelmsford, the High Commissioner for Canada, and Bishop Gore.

In connection with the Royal Microscopical Society a Paper Industries Section is in course of formation. It will deal with researches relating to timber, wood-pulp, paper, etc. All interested in the subject and willing to assist are invited to communicate with Mr. J. Strachan, 74 Blenheim Place, Queen's Cross, Aberdeen.

The Crown Prince of Japan, accompanied by Prince Kan-in and a large party, which included Admiral Ogouri and seven senior naval officers, visited Greenwich Observatory on Monday, May 16. The party was received by the Astronomer Royal, Sir Frank Dyson, and the two chief assistants, Mr. H. Spencer Jones and Mr. J. Jackson, and examined with interest the chief instruments in the observatory.

At the meeting of the Franklin Institute, Pennsylvania, held on May 18, the Franklin medal and certificate of honorary membership were presented to M. Jusserand, French Ambassador to the United States, for Prof. Charles Fabry, of the University of Paris, for his studies in the field of light radiation. The Franklin medal and certificate of honorary membership were also presented to Mr. Frank J. Sprague, New York City.

The Wild Birds Advisory Committees appointed for England and Scotland by the Home Secretary and the Secretary for Scotland to advise regarding the protection of wild birds held their first meetings on May 12, and a joint meeting on May 13, when general questions of wild bird protection in Britain were discussed. The chairmen of the committees are Viscount Grey of Fallodon, K.G., and Mr. H. S. Gladstone, and the secretary of the Scottish committee is Dr. James Ritchie, Keeper of the Natural History Department, Royal Scottish Museum, Edinburgh.

THE prolonged pause in the seismic activity of the well-known Comrie centre seems to be coming to an end. Towards the close of a similar, but briefer, pause from 1801 to 1839 slight shocks gradually became more frequent, until they culminated in the strong earthquake of October 23, 1839. There was no pronounced movement between the summer of 1898 and that of last year. On July 21, 1920, a shock of intensity 3 (Rossi-Forel scale) occurred, followed by one of intensity 4 on September 14. On April 30 last a still stronger earthquake, the most distinct known to the present inhabitants, was felt at 10.35 a.m. (Greenwich mean time). The shock was strong enough to throw down crockery from shelves, and was accompanied by the usual sound, like the firing of guns.

MR. G. SHEPPARD, of Edmonton, Alberta, informs us that in view of the coming importance of the MacKenzie River Basin of the North-West Territory of Canada by reason of the oil strike made there in 1919, the Imperial Oil, Ltd., has purchased two monoplanes, which are to be used for general reconnaissance and topographical work in these unknown regions. An aerodrome has been established at Peace River Crossing, about 300 miles north of Edmonton, and from this base the planes will operate as far as Fort Norman and the Great Slave Lake areas. The journey takes, normally, three to four weeks under favourable conditions, but it can be made easily in three days by air. The aeroplanes are to be equipped with suitable cameras, by which it will be possible to photograph all water-courses and similar features of the landscape. These photographs will be of value to surveyors and others for checking up the country without using ordinary topographical methods.

AT the annual general meeting of the Institution of Civil Engineers held on April 26, the result of the ballot for the election of officers for the year 1921–22 was declared as follows:—*President:* Mr. W. B. Worthington. *Vice-Presidents:* Dr. W. H. Maw, Mr. C. L. Morgan, Mr. B. Mott, and Sir William H. Ellis. *Other Members of Council:* Dr. C. C. Carpenter, Mr. G. M. Clark, Dr. P. C. Cowan, Col. R. E. B. Crompton, Mr. M. Deacon, Sir Archibald Denny, Bart., Mr. W. W. Grierson, Sir Robert A. Hadfield, Bart., Mr. K. P. Hawksley, Sir Brodie H. Henderson, Mr. E. P. Hill, Mr. G. W. Humphreys, Mr. S. Hunter, Mr. H. G. Kelley, Mr. C. R. S. Kirkpatrick, Mr. F. W. MacLean, Mr. H. H. G. Mitchell, Sir Henry J. Oram, Mr. F. Palmer, Mr. G. Richards, Capt. H. Riall Sankey, Sir John F. C. Snell, Mr. W. A. P. Tait, Mr. E. F. C. Trench, Prof. W. H. Warren, and Sir Alfred F. Yarrow, Bart.

THE members of the Gilbert White Fellowship have resolved to commemorate the bicentenary of the birth of the renowned naturalist whose name their organisation bears by erecting a permanent memorial at Selborne, and by undertaking a regional survey of the parish rendered famous by his great work, "The Natural History of Selborne." The memorial is to take the form of an outdoor bench or seat in stone and timber. The results of the regional survey it is hoped to publish as the work proceeds, so as to make them immediately available to all interested. Many admirers of Gilbert White outside the circle of the fellowship are likely to be glad of the opportunity of taking part in this tribute to his memory. Such contributions as those interested may feel disposed to make should be sent to Messrs. Grindlay and Co., bankers, 54 Parliament Street, London, S.W.1, to be credited to the account of the Gilbert White Memorial Fund, or to the honorary secretary, Winifred M. Dunton, 18 Crockerton Road, Wandsworth Common, London, S.W.17.

AN important step has been taken in America for the presentation of science and scientific facts to the lay public by the formation of a Science Service (*Science,* April 8). The charter is a wide one, authorising the organisation to publish books and magazines, to conduct conferences and lectures, and to produce kinematograph films; the function will be that of liaison officer between scientific circles and the general public. The governing board will consist of ten men of science and five journalists, and any profits which may accrue will be devoted to the development of new methods of popular education in science. The present board of trustees consists of three representatives from the National Academy of Science, three from the American Association for the Advancement of Science, three from the National Research Council, three from the Scripps Estate, which is financing the undertaking, and three professional journalists, under the presidency of Dr. W. E. Ritter, director of the Scripps Institution for Biological Research of the University of California. Dr. Edwin E. Slosson, who for some twelve years was professor of chemistry in the University of Wyoming, and for the past seventeen years has been literary editor of the *Independent* of New York, has been chosen as editor. At present the Science Service will not publish any periodical of its own; it is considered that better results will be obtained by directing attention to the various journals of popular science already in existence, and by supplying newsagencies with authentic, popular articles. The headquarters of the institution have been established provisionally in the building of the National Research Council, 1701, Massachusetts Avenue, Washington, D.C.

DR. T. W. FULTON, scientific superintendent of the Fishery Board for Scotland, has just retired after a service of thirty-four years. The Scottish Scientific Department owed its institution to the recommendation of the Dalhousie Trawling Commission, and in 1888, when Dr. Fulton was appointed, had been in existence for only a few years. In England the scientific study of the sea in connection with fisheries was taken up by the Plymouth Laboratory, and later by certain of the Sea Fisheries Committees, two of which, those of Lancashire and Northumberland, have much good work to their credit. The fisheries are a very intricate, many-sided subject, and Dr. Fulton has laboured to solve many problems which have cropped up in the Scottish administration. The attempt has been made to render the statistics as

accurate and informative as possible in an industry which does not lend itself readily to minutely made records. In order to locate the regions in which the fishes were captured by means of the trawl, Dr. Fulton devised the scheme subdividing the North Sea into equally sized divisions numbered consecutively. This arrangement was adopted and found to be of great service. Dr. Fulton has served during the past twenty years as one of the experts on the International Committee for the Exploration of the North Sea, a body which has published many important reports dealing with fisheries biology. In 1911 a Departmental Committee of which he was a member inquired into the Scottish fishing industry; the wide extent and thoroughness of its labours are indicated by the large report which it issued. Dr. Fulton's publications deal with the development, distribution, and migrations of fishes; they are numerous and of great interest and value.

In an account of the leeches of the Chilka Lake (in the province of Bihar and Orissa) Mr. W. A. Harding records (Memoirs Indian Museum, vol. v., 1920) the occurrence of a colour variety of *Glossosiphonia heteroclita*, a species well known to occur in fresh-water in North America and throughout the greater part of Europe, but now recorded from India for the first time. Mr. Harding has received examples collected in many other parts of India, and the species is evidently widely distributed there. A new species of Piscicola, from fish, and one of Placobdella, from mud-turtles of the genus Emyda, are also described.

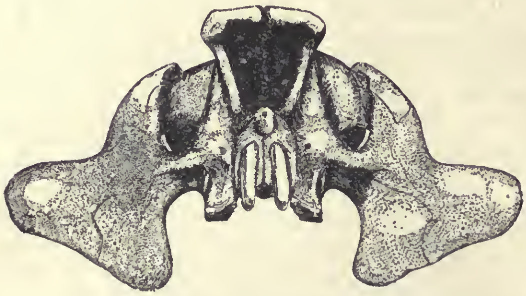
As a result of the late war and the consequent dearth of foodstuffs in certain parts of Central Europe, increased interest is being aroused in the wider utilisation of wild plants—more especially fungi—as food for human consumption. An association has been formed in recent years, having its headquarters in Heilbronn a. N., styled the "Pilz- und Kräuterzentrale," amongst the main objects of which are the fostering of the study of fungi and the dissemination of information, particularly as regards the nutritious qualities of the various edible kinds and the properties of those that are noxious or specifically poisonous, amongst the lay public. In furtherance of its aims a congress of mycologists is being arranged under the auspices of the association to be held in Nürnberg during the coming autumn. The association issues a monthly periodical, *Der Pilz- und Kräuterfreunde*, now in its fourth year of publication. The articles in this periodical are naturally more or less of a popular nature, but descriptions of new fungi are also included. One of the recent issues contains a description, with a coloured plate, of a new poisonous species of agaric, *Inocybe lateraria*. In the list of supporters of the association are to be found such well-known names as Günther-Beck v. Managetta, Bresadola, Falck, and Lindau.

The National Institute of Agricultural Botany has recently published the report of its Potato Synonym Committee for the year 1920. The necessity for reducing to order the chaos existing in the nomenclature of potato varieties has become more urgent than ever in recent years, owing to the fact that some varieties are immune to the dreaded wart disease, while others are susceptible. Two hundred and forty-two varieties are dealt with in the report, and they are classified in forty-two groups. Immunity or susceptibility to wart disease is generally indicated. In a large number of cases the varieties, although possessing different names, were found to be indistinguishable in morphological and certain physiological characters (such as time of maturity, immunity or otherwise to wart disease) from well-known types such as "Up-to-Date," "Abundance," etc., so that in practice one and the same variety may possess many names. It is proposed to publish an annual handbook of potato synonyms, the practical value of which will be considerable. Nevertheless, it is to be hoped that the institute will not rest content with a mere indexing of names. What is really required is a detailed and scientific monograph of the leading types of potato varieties at present in cultivation, with adequate illustrations and descriptions of their differentiating characteristics. The preparation of such a monograph would entail a considerable amount of additional effort; but a better opportunity for embarking on such a project is scarcely likely to occur than that now presented by the work of the National Institute at its Ormskirk Trial Grounds, while it would be difficult to find men more thoroughly equipped for the enterprise than those who form the Synonym Committee.

The annual report of the Marlborough College Natural History Society for the year ending Christmas, 1920, has just been received. It forms an interesting record of the work carried out by this active and vigorous association. No fewer than fourteen papers were read to the astronomical section dealing with such diverse subjects as the moon, stellar photometry, tides, and relativity. The botanical, ornithological, and entomological sections also receive notice in the report. Their activities were confined mostly to recording the appearance of plants, birds, and insects in the neighbourhood, and the results provide useful contributions to the knowledge of the local natural history. The report concludes with a summary of the meteorological observations made at the college during the year; maximum, mean, and minimum barometric and thermometric readings for the several months are given, together with remarks on observations of wind, rainfall, and sunshine for similar periods. We are glad to see that this useful society is, according to the annual balance-sheet, in a sound position and proposes to carry on and, if possible, extend its labours to other branches of natural history.

The Queensland Museum recently obtained from post-Tertiary sand on the Darling Downs a marsupial cranium apparently of the species *Nototherium dunense*, founded by De Vis in 1887 on some mandibles and cranial fragments. The new skull is described and figured in the Memoirs of the museum (vol. vii., part 2) by the director, Mr. H. A. Longman, who feels impelled to establish for the species a new genus, Euryzygoma. The character that suggests the name is the enormous relative width given to the skull by

the extension, from the lower outer angle of each cheek-bone or zygomatic arch, of a large side-process buttressed by a horizontal platform beneath the orbit. Mr. Longman considers that these processes were for the support of large cheek-pouches, as in the pocket gophers of North America. However that may be, such extensions are characteristic of the Nototheres, and an exaggeration of the character, with the correlated modifications, would scarcely warrant the generic separation of this species from *Nototherium*



Front view of the cranium of Euryzygoma, slightly restored. Actual width 680 mm.

Mitchelli and *N. tasmanicum*. Mr. Longman, however, states that the upper premolar tooth, on which some stress has been laid by classifiers of marsupials, is oval in the normal Nototherium, but subtriangular in Euryzygoma. From the half-tone reproduction of a greatly reduced photograph it is impossible to check the alleged differences. In all other technical respects Mr. Longman's presentation of his results calls for praise. He is also to be congratulated on an interesting discussion of the most remarkable Diprotodont yet discovered.

ALASKA magnetic tables and magnetic charts for 1920 have been published by the U.S. Coast and Geodetic Survey as Special Publication No. 63, prepared by Daniel L. Hazard, Assistant-Chief, Division of Terrestrial Magnetism. Charts are given for the several magnetic elements, declination, inclination or dip, and horizontal force or intensity. The area covered by the discussion includes not only Alaska, but also its boundary waters, parts of the North Pacific, the Bering Sea, and the Arctic. Declination and dip are given on the charts to each 1° and the horizontal force for intervals of 0·01 C.G.S. unit. Results are for observations since 1870, and the data now published are said to be sufficiently numerous to show areas of local disturbance, some of which are remarkable. Lines of equal annual change of declination are shown on the isogonic chart, but they are stated to be only rough approximations to the truth. East declination is decreasing in Alaska except in the south-eastern portion, where the change is negligible. It is not considered advisable at present to attempt to draw lines of equal annual change of dip or of horizontal force. The tabular matter shows that the dip appears to be decreasing in the greater part of Alaska at the rate of 1′ or 2′ a year, and that the annual change of horizontal intensity is decreasing in the southern part of the territory and increasing in the northern, but the rate of change is small.

WE have received from Dr. J. Newton Friend a copy of his paper entitled "Iron in Antiquity," reprinted from the Transactions of the Worcestershire Naturalists' Club. Dr. Friend recalls the statement of Cæsar that the Britons were accustomed to use bars of iron in place of coins as currency. Several hundreds of these, which have escaped, more or less, the ravages of time, have been found and placed in different museums, notably the British Museum and the local museum at Worcester. They resemble swords and consist of a flat and slightly tapering blade with blunt vertical edges. Owing to corrosion all the bars have suffered some loss in weight, but many of them have been only slightly oxidised, and a rough estimate of their original weight can be made. The weights are found to approximate 309 grams, or some multiple or sub-multiple of this amount. In all, six different denominations have been found. In spite of their resemblance to swords, Dr. Friend advances good reasons for considering that these are the currency bars referred to by Cæsar, the use of which, indeed, dates back to the early Greeks, and survives to-day in some parts of Africa. His paper also deals at some length in an interesting way with early British water-clocks.

THE Dewey decimal system of classifying books in a reference library is being adopted in America, and modifications of it are widely used. The radio laboratory of the Bureau of Standards has extended this method and applied it to the classification of books and pamphlets in its library. In the Dewey classification "radio" would be represented by 621·384. The number 600 denotes the class (useful arts), the number 20 denotes the division (engineering), and the number 1 denotes the section (mechanical). Similarly, 0·300 stands for "electrical," 0·080 for "communication," and 0·004 for "radio." As the library is a collection of matter dealing with radio, the number 621·384 is denoted by R, and a further number of three figures is added. For instance, R211 stands for "resonance methods of measuring wavelengths." R200 contains information on "radio measurements and standardisation," R10 denotes "theory," and R1 "statistics." An essential part of the method is the alphabetical index. We look up, for instance, "resonance methods" and find R211. This gives us the number of the shelf in the library on which the required books or pamphlets will be found, the shelves all being classified in numerical order. The books on the adjacent shelves also treating of cognate subjects can sometimes be usefully consulted at the same time. The classification is good and the alphabetical index very complete. We missed, however, the word "thermionic."

MESSRS. C. BAKER, of 24 High Holborn, W.C.1, have issued a new edition (No. 72) of their catalogue of second-hand scientific instruments. As is customary in these lists, the items are grouped in sections according to the subjects with which they are related. Twelve such sections appear in the list before us, five of which deal with apparatus which may be classed as physical. Section I., dealing with microscopes and their accessories, includes particulars of

a number of microscopes both large and small, and a long list of object-glasses, eye-pieces, condensers, etc. The astronomical section (No. III.) describes numerous telescopes of different types and a very varied collection of eye-pieces. Section VII. is devoted to what may be termed academic physical apparatus, and Section X. to photographic apparatus. The book list (Section XI.) includes a number of books and journals, among which we notice vols. xxviii.–civ. of NATURE.

MESSRS. G. BELL AND SONS will publish next month "Motya: A Phœnician Colony in Sicily," by Joseph I. S. Whitaker (of Malfitano, Palermo). Motya was one of the latest sites occupied by the Phœnician colonisers of Sicily. Though its exact position was long a matter of doubt, it is now identified by archæologists with the small island of San Pantaleo at the north-west extremity of Sicily. Recent excavation undertaken by its owner, Mr. Whitaker, has confirmed this conclusion, and the forthcoming volume contains a detailed account of his discoveries.

IN a paper entitled "Studies on Phototropism in Solution," part i. (Journ. Amer. Chem. Soc., vol. xliii., 1921), Prof. B. K. Singh indicates some interesting cases of phototropism in solution which he is investigating, and points out that his preliminary results do not fall into line with Senier and Shepheard's explanation that phototropic transformations are due to extramolecular rearrangements.

UNDER the title *Dactylography* a bimonthly magazine is to appear on July 1. It will deal chiefly with the evidence for criminal and other identifications by means of finger-prints; but attention will also be given to a study of the detective aspects of footprints, tattoo marks, deformities, and related matters. The magazine will be conducted by Mr. Henry Faulds, Regent House, Hanley, Stoke-on-Trent.

MR. F. EDWARDS, 83 High Street, Marylebone, W.1, has issued at an opportune moment an interesting catalogue (No. 413) of nearly four hundred entries of books, manuscripts, letters, documents, and engravings relating to Napoleon and his times. Many choice works are offered for sale. The list can be obtained free of charge.

MR. P. BRUCE WHITE directs attention to a misinterpretation indicated by a sentence in the article on researches on bee disease in the issue of NATURE for April 28, p. 284. Instead of "The tracheæ become darkened and ultimately black by the increasing deposition of chitin," it should read: ". . . by the increasing amount of fæcal matter deposited by the mites."

Our Astronomical Column.

COMETS.—A new comet 1921*c* was discovered by M. Dubiago, Petersburg, on April 29. The following orbit has been received by telegram:—

$$T = 1921 \text{ May } 7{\cdot}611 \text{ G.M.T.}$$
$$\omega = 104^\circ\ 45'$$
$$\Omega = 66^\circ\ 4'$$
$$i = 21^\circ\ 42'$$
$$\log q = 0{\cdot}02731$$

Ephemeris for Greenwich Midnight.

	R.A. h. m. s.	N. Decl. ° ′	Log *r*	Log Δ
May 20	8 56 45	39 46	—	—
24	9 21 6	37 33	0·0419	9·9661
28	9 44 44	34 58	0·0492	9·9620

Herr Reinmuth, of Königstuhl, obtained a twelve-minute exposure plate of Reid's comet on April 30. It shows a faint tail 40′ long in P.A. 266°, slightly curved at its extremity towards smaller P.A. There is also a group of short streamers with centre in P.A. 225°.

Corrections to the ephemeris of Pons-Winnecke:—May 22, $-31\frac{1}{2}$m., $-1^\circ\ 0'$; May 26, -45m., $-5'$; May 30, -59m., $+1^\circ\ 43'$. It is a curious coincidence that the three comets now visible are all circumpolar, and their perihelion distances are nearly equal, all being slightly in excess of unity.

Mr. Denning writes that on April 10 Winnecke's comet was an easy object in a $6\frac{1}{2}$-in. refractor, power about 20. The comet was estimated to be about 9th magnitude, and some 5 or 6 minutes of arc in diameter, though it was difficult to define exactly the outer faint limits of the nebulosity. As the comet is brightening, it should become rather conspicuous even in small telescopes after the present moon has left the evening sky, on about May 25. On that date the comet will be 17 millions of miles from the earth, and its position in the heavens will be two degrees south of δ Cygni. It is travelling rather swiftly to the south-east, and on May 30 will be eight degrees south-south-east of α Cygni. It will then probably be about 7th magnitude, but many comets vary in their light in an inexplicable manner.

THE ECLIPSING VARIABLE U CEPHEI.—The study of eclipsing variables, from which a large amount of information on the sizes, densities, and brightness of the components may be gained, played a large part in the development of the theory of giant and dwarf stars. It is therefore not surprising that Mr. R. S. Dugan, one of the assistants of Prof. H. N. Russell at Princeton, has produced a monograph on U Cephei. The eclipse of the primary star (which is of type A_0) is total, so that we get the spectrum of the secondary isolated. Miss Cannon has recently determined its type as K_0. Since this is the larger star, but the less luminous, both would appear to be in the giant stage.

The light-comparisons were made visually, and in the course of them reason was found to suspect the variability of B.D. 81·27° and 81·30°. The secondary minimum, being an annular eclipse, gives information as to the degree of darkening at the limb. In the final elements the limb-light is taken as one-third of that at the centre. The orbit is sensibly circular; taking its radius as unity, the radii of the stars are 0·20 and 0·32, and the inclination of orbit plane 86·4°. The densities are (somewhat conjecturally) given as 0·214 and 0·022 of that of the sun. From asymmetry in the light-curve it is concluded that the bright star rotates more rapidly than the period of revolution, producing a tidal lag of 24°. A further result of tidal friction is traced in the lengthening of the period of variation by 9 seconds in 60 years; this is indicated with considerable probability by some early observations of magnitude by Schwerd and Carrington. The system thus furnishes an interesting illustration of tidal evolution.

Æther Waves and Electrons.[1]

By Sir William Bragg, K.B.E., F.R.S.

Newton put forward a corpuscular theory of light, and Huyghens believed that it was essentially a wave motion. Each gave wrong reasons for his belief. Newton argued that it ought to be possible to see round a corner, since the passage of waves round a corner was a common effect. Huyghens declined the corpuscular theory on the grounds that corpuscles could not go fast enough, and that if two people looked into each other's eyes the corpuscles must hit each other and prevent mutual vision. But the wave theory carried all before it, and, developed by Young, Fresnel, and other workers, proved to be capable of explaining optical phenomena in perfect fashion.

With the advent of X-rays and radio-activity the process of radiation as a whole is seen to depend in part on the movement of electrons. In the X-ray bulb, to take an example, a stream of electrons, which is truly a corpuscular radiation, strikes a block of metal in the centre of the tube. Energy of radiation is carried outwards through the walls of the tube in the form of X-rays; that is to say, of wave motions in the æther. When they strike matter, such as the film of a photographic plate, the wave radiation disappears and is replaced by moving electrons which produce all the well-known effects ascribed to X-rays. It is probable that this mutual plane of waves and electrons is carried throughout the whole realm of radiation, and the ultimate explanation of all optical problems must involve the recognition of corpuscular radiations, at times replacing and being replaced by the waves. Thus once more the corpuscular theory appears again as a working hypothesis.

But in its relation to the wave theory there is one extraordinary and, at present, insoluble problem. It is not known how the energy of the electron in the X-ray bulb is transferred by a wave motion to an electron in the photographic plate or in any other substance on which the X-rays fall. It is as if one dropped a plank into the sea from a height of 100 ft. and found that the spreading ripple was able, after travelling 1000 miles and becoming infinitesimal in comparison with its original amount, to act upon a wooden ship in such a way that a plank of that ship flew out of its place to a height of 100 ft. How does the energy get from one place to the other?

Very lately considerable new information has come to hand regarding the way in which atoms play a part in this extraordinary transference of energy. In many ways the transference of energy suggests the return to Newton's corpuscular theory. But the wave theory is too firmly established to be displaced from the ground that it occupies. We are obliged to use each theory as occasion demands and to wait for further knowledge as to how it may be possible that both should be true at the same time. Toleration of opinions is a recognised virtue. The curiosity of the present situation is that opposite opinions have to be held and used by the same individual in the faith that some day their combined truth may be made plain.

[1] Summary of the Robert Boyle lecture delivered at Oxford on May 12.

The Natives of the Gilbert Islands.

At a meeting of the Royal Anthropological Institute on April 21, Dr. W. H. R. Rivers, president, in the chair, Mr. Arthur Grimble read a paper entitled "From Birth to Death in the Gilbert Islands." The paper, which was of considerable importance, as it dealt with a people about which we possess little information, described in detail the ceremonies used at marriage, birth, and death by the Gilbertese-speaking communities.

The rules relating to consanguinity among the Gilbertese are genealogical in character, and evidently allied to the Polynesian systems as typified by the Samoan; but the concubitant relations which exist between a man and his wife's sisters are of a type generally found in Melanesian communities. An extremely interesting relationship is that of *Tinaba*, under which a woman owes both filial and sexual duties to the brothers of her husband's father and a man to his wife's mother's sister. Incest is regarded with horror, and the hatred of the sun for incestuous couples is much stressed in native myth.

There were several forms of marriage ceremony in vogue. On certain islands marriage by capture was practised. Rather more common was the fishing fiction, in which the suitors seated in a loft let down lines into the room underneath, where the girl made a pretence of being caught by one of them. This act was succeeded by the anointing of the couple with coco-nut oil, and the union was complete. The most usual form of ceremony, however, was that known as *te iein*, of which the essential motive was to test the virginity of the bride. After birth mother and child remained for three days in the place of confinement, while the infant's soul was encouraged into its body by merrymaking, in which fire played an important part.

A boy's training was conducted with the view of excluding all sexual interests. The cutting of his hair from time to time was performed with rigid ceremonial, until the climax was reached in the initiation ceremonies (which were chiefly trials by fire) undergone when his pectoral and axillary hair was well in evidence. After submitting to these ordeals he was isolated until he passed certain tests of strength and endurance. He would then be allowed to marry.

A girl on reaching the age of puberty was isolated in a darkened room for the purpose of bleaching her skin and thus rendering her like the fair-skinned ancestral gods of the race. On release from the bleaching-house she was ready for marriage.

Great precautions were taken at death to drive away the soul. The body was usually buried on the fourth day, sometimes on the tenth; occasionally it was sun-dried and kept for a number of years. The skull was often kept. In the lagoon islands the body lay on its back, fully extended, with toes pointing up; on Banaba the knees were flexed outwards in a frog-like position.

The paper closed with a summary of the beliefs concerning the destination of the departed spirit and of the possible inferences which may be drawn therefrom. The names of the various bournes of the dead have an extraordinary resemblance to certain place-names in Indonesia.

Parliamentary Visit to the Rothamsted Experimental Station.

ON May 13 the Minister of Agriculture (Sir Arthur Griffith-Boscawen) and the Agricultural Committee of the House of Commons, together with members of the House of Lords interested in agriculture, visited the Rothamsted Experimental Station at the invitation of the chairman, the Right Hon. Lord Bledisloe, and the director, Dr. E. J. Russell.

Fortunately the weather was fine, and the plots were inspected under favourable conditions. The fields visited included those in which the classical experiments on the growth of wheat, barley, and meadow-grass are conducted, and the salient features were demonstrated by members of the staff. Other experiments were shown to ascertain the comparative fertiliser effects of ammonium chloride and ammonium sulphate on cereals and potatoes, the effects of potassium and magnesium salts on potatoes, the most suitable time of application of nitrogenous fertilisers to cereals, and the relationship between the quantity of fertiliser used and the crop obtained, the last being particularly interesting inasmuch as the effectiveness of small and moderate dressings increases more rapidly than the dressing, while with larger quantities the effectiveness falls off. The experiments on electro-culture were demonstrated, as also was the recent work on the production of farmyard manure without the intervention of animals.

The whole of the laboratory work was seen, ranging over the chemical, physical, statistical, and biological sciences, the last including bacteriology, botany, entomology, mycology, and protozoology. Many interesting specimens were shown, and there were other exhibits to illustrate the work going on in the study of the soil, the growing plant, and plant diseases.

In his speech after lunch Lord Bledisloe welcomed the guests and expressed the hope that this first visit would be followed by many others of those members of both Houses of Parliament interested in agriculture. He directed attention to the report shortly to be issued, in which the work is discussed in full detail and its bearing on agricultural practice indicated. Dr. Russell outlined the more important investigations now proceeding, and emphasised the necessity for the development of a sound agricultural science which could be of use to the teacher, the expert adviser, and the progressive farmer.

The Minister of Agriculture expressed his recognition of the great importance of the work being done at Rothamsted and other research institutions, and emphasised the fact that in such work lies one of the best hopes for agriculture. Legislative enactments are of course essential, but they cannot provide the material for progress and development that is furnished by sound scientific investigation. Although the necessity for economy in every branch of public activity was insistent, he would, so far as it lay in his power, see to it that agricultural research should not be called upon to suffer in the name of a false economy.

Habits of the Hedgehog.

THE Memoirs and Proceedings of the Manchester Literary and Philosophical Society for 1918–19 contain a paper by Mr. Miller Christy on "The Ancient Legend as to the Hedgehog Carrying Fruits upon its Spines." In the introduction to his paper Mr. Christy pointed out that the legend is very old, and that it is important to remember that since the hedgehog is almost wholly a nocturnal animal it is difficult to verify statements regarding its habits by actual observation. The earliest recorded statement that hedgehogs carry fruit on their spines was made by Pliny the Elder; Claudius Ælianus, who wrote about A.D. 250, relates a similar tale. No further evidence is recorded until the twelfth century, while during the Middle Ages a number of writers and poets of many countries related stories of hedgehogs carrying various fruits in this way. Mr. Christy takes the view that most of these people copied blindly the statements of their predecessors. Of the more modern naturalists Buffon discredited the legend, though other naturalists of his time stated definitely that they had witnessed the transportation of fruit by these means. Among present-day writers on natural history little credence is given to the tale, though two cases are reported in which the evidence in support is regarded as trustworthy. We reprint below the substance of the summary of the evidence and the conclusions based thereon with which Mr. Christy concluded his paper.

The hedgehog-and-apples legend is at least two thousand years old—more if it originated with Aristotle, as has been stated; also it is prevalent throughout practically the whole of Europe. There must have been (one would think) some substratum of actual observed fact, renewed from time to time, to keep any legend of the kind alive so long and to cause it to become so widespread. Nevertheless, it cannot be denied that most modern writers on mammals, if they refer at all to the old legend, either dismiss it as too absurd to be worth a moment's consideration or at least show themselves decidedly sceptical.

But is the story really so incredible, after all? Are we not apt, in these highly scientific days, to become too contemptuously sceptical in regard to all ancient legends of the kind, and to forget that, however absurdly improbable they may appear at first sight, not a few of them have been shown to have some genuine basis in fact—often slight, but sufficient to substantiate and justify them? In all such cases a cautious scepticism should be, of course, maintained up to a certain point; but it is well to remember a dictum to which the late Prof. Huxley gave utterance many years ago: "I have always felt a horror of limiting the possibilities of things."

But before accepting the old legend unreservedly, there is one point which requires first to be considered: Does the hedgehog ever eat fruit? As to this crucial question many contradictory opinions have been expressed. The truth seems to be that the creature undoubtedly affects, in the main, an animal diet, consisting chiefly of small reptiles, worms, snails, slugs, insects, beetles, birds' eggs, and the like. In confinement it will readily eat meat, either cooked or uncooked, bread and milk, and many such substances as are usually given to cats and dogs. Its partiality for eggs has gained for it a very bad name among gamekeepers, poultry-keepers, and such people. In all probability, however, the robberies of eggs from the nests of game-birds and poultry which are usually ascribed to the hedgehog are really the work of some other animal.

On the other hand, there is equally little doubt that on occasion the hedgehog will readily subsist on a vegetable diet. Knapp says ("Journal of a Naturalist," third edition, 1830, p. 130): "In the autumn crabs, haws, and the common fruits of the hedge constitute its diet." Macgillivray asserts ("British Quadrupeds," 1838, p. 119) that it "eats fruits, especially apples that have fallen from the trees."

Yet another cognate point which has to be considered is: Does the hedgehog lay up a store of food for the winter? Obviously, of animal food *he could not*. Of vegetable food, however, *he might*, and some writers have stated explicitly that he does. Yet others of at least equal authority have stated that he does not; and the author agrees with them. He has seen many nests of hedgehogs dug out of rabbit-holes when ferreting in winter, but none has ever been accompanied by a store of winter food. It is on this account, no doubt, that the animal's hibernation is by no means complete, and that he sometimes leaves his winter nest and comes abroad even on cold days. Probably the fruit of various kinds which hedgehogs have been seen carrying on their spines has been intended by them rather for immediate consumption than as winter sustenance.

Several friends and correspondents of the author—some excellent naturalists among them—have advanced the argument that, as they have kept many tame hedgehogs and have never observed them even attempting to transport fruit on their spines, the habit cannot be one they practise in a state of nature. This argument seems to be entirely unsound. The habits of animals in nature and in confinement are often different; and in this particular case it may be urged that a hedgehog in confinement, being (in a way) at home, would scarcely be likely to feel a need to carry food home.

From the foregoing it becomes clear that there are, beyond doubt, not a few cases, both ancient and modern, in which a hedgehog has been *actually seen* carrying objects impaled upon the spines upon its back—in most cases various kinds of fruit; in one case eggs of the pheasant. Unfortunately, none of these observations (though made by persons whose *bona fides* is in little doubt) can be regarded as wholly conclusive, all being to some extent second-hand or made by persons of little education. Nevertheless, taking them in the mass and viewing them in conjunction with the very ancient and extremely persistent legend relating to the matter, it seems impossible longer to doubt that, *at times at any rate*, the animal really does transport fruit in the way asserted.

There is yet another legend pertaining to the hedgehog (and almost as ancient and widespread as the fruit-carrying legend), namely, that it sucks the milk of cows grazing in the fields. This statement, in the crude form in which it is usually made and understood, is a manifest impossibility. In the first place, no hedgehog by stretching up would be able to reach the teats of any cow of ordinary stature; and, even if it could do so, the fact remains that the hedgehog's mouth is far too small to allow it to suck milk effectively from the teats of any such cow.

Nevertheless, the legend in question is probably true in a way, and a perfectly natural explanation as to its origin can be given. We know well, from the evidence of hedgehogs kept in confinement, that the animal is exceedingly fond of milk; and there can be no possible doubt that, in a state of nature, it would take every opportunity to secure milk. Obviously, it could do this only when a cow was lying down. In such a case, as is well known, milk often runs from the teats of a milch cow; and there can be little or no doubt that the milk-sucking legend has originated in the fact of a hedgehog having been seen sucking drops of milk from the teats of a recumbent cow or from the ground immediately after she has risen.

The "Flight" of Flying-fish.

APROPOS of the recent correspondence concerning the "flight" of flying-fish, Prof. W. Galloway has sent us a copy of a paper ("The Flying-fish," Trans. Cardiff Nat. Soc., vol. xxiii., 1891) in which he discussed the whole subject thirty years ago. His own observations, made from the bows of a ship, are in agreement with those of Prof. Wood-Jones and of Mr. J. S. Huxley: the impetus is given by the tail, the pectoral fins are used as planes, and new impetus can be gained by immersing and vibrating the lower lobe of the tail. Prof. Galloway adds further interesting particulars. Changes of direction made in air are usually slight, the fish describing arcs of very large radius; if a sudden change is required, the fish drop into the water, to emerge almost instantly headed in the new direction. The ordinary velocity of flight is from 25 to 35 miles per hour. When the wind is very strong (25 to 30 miles per hour) the fish are unable to rise with it, falling back into the water almost immediately. When, therefore, they are startled by a ship travelling with a strong wind, they rise *against* the wind, and then, having gained sufficient velocity, tilt right or left to describe a semicircle with radius of 40 or 50 ft. and sail down-wind for very long distances (200–300 ft. or more); if desirous of flying again they do not attempt to drop their tail into the water, but submerge totally, leap out once more against the wind, and once more turn. Prof. Galloway also summarises the previous literature. One point deserves mention. Möbius (*Zeit. wiss. Zool.*, vol. xxx., 1878, Suppl., p. 343) agrees with various observers that marked vibration of the pectoral fins may and does occur (Prof. Galloway states that it usually does so immediately on emergence). This, Möbius states, is solely passive, due to the air resistance when the "wings" happen to be held parallel to the plane of flight; similar effects can be produced artificially on a bird's wing or a piece of stiff paper. We are thus, it seems, warranted in regarding the following points as proven:—

(1) The pectoral fins of the true flying-fish act as lifting and, to some extent, as turning planes in air. (2) Rapid turns are made under water. (3) The impetus to flight is not given by the pectoral fins, nor is it the result of a single leap into the air after the fashion of a salmon. A rush is made which takes the fish clear of the water, but at a very small angle with the surface, and by means of motion of the elongated lower lobe of the tail additional motive power is provided during the traverse of several yards. (4) When velocity slackens it can be re-acquired repeatedly by immersing and vibrating the lower lobe of the tail. (5) Vibration of the pectoral fins does occur, but is probably a passive effect. (6) In a strong wind flying-fish can rise only against the wind.

The Royal Society Conversazione.

The first conversazione this year of the Royal Society was held at Burlington House on May 11, and was attended by a large number of fellows and guests, who were received by the president, Prof. C. Sherrington, and the officers of the society. Many exhibits of objects and apparatus of scientific interest were shown, and we have grouped together those on related subjects in the subjoined summaries of some of them from the descriptive catalogue.

Prof. K. Onnes, Sir R. A. Hadfield, and Dr. H. R. Woltjer: Apparatus and specimens used in research on the influence of low temperatures on the magnetic properties of alloys of iron with nickel and manganese. A series of iron–manganese and iron–nickel alloys was exposed to the temperatures of liquid air, liquid hydrogen, and liquid helium respectively and the specific magnetism tested after return to atmospheric temperatures. Tests were also made during immersion in liquid hydrogen ($-253°$ C.). The alloys with the higher percentages of manganese cannot be made magnetic even by immersion in liquid helium ($-269°$ C.). The existence of one magnetic and one non-magnetic manganese–iron compound is shown to be probable.

Messrs. Evershed and Vignoles, Ltd.: Needham's pulsator system of speed measurement and control. This system provides a sensitive electrical means of measuring speed, and may be employed as a speed telegraph of a novel and extremely trustworthy character. In addition to signalling from one or a number of control positions, measurements may be effected simultaneously and independently at a number of positions, so that the system is one of great flexibility. It also indicates the direction of rotation. The system is extremely suitable for use on ships, in power stations, and in other places where the measurement or indication of speed is desired at a distance from the moving machinery

The Hon. Sir Charles Parsons and Mr. Stanley S. Cook: An attempt to reach high instantaneous pressure by the collapse of a hollow sphere of lead under external pressure suddenly applied by an explosive. The sphere is made up of two hemispheres placed together with tissue-paper between and soldered around the periphery of the joint. In the cavity is placed the substance to be compressed. If its final diameter in nuclear form is 1/200th that of the initial hollow, and the pressure of the explosive 20 tons per square inch, the nuclear pressure produced is 1,000,000 tons. The explosive is fired in six places simultaneously.

Cambridge and Paul Instrument Co., Ltd.: Apparatus similar to Mr. C. T. R. Wilson's original cloud expansion apparatus, but improved by Mr. T. Shimizu so that α-, β-, and X-rays may be continually demonstrated.

Mr. E. A. Griffiths: Liquid oxygen vaporiser. The liquid oxygen is contained in a metal vacuum vessel. The emission of gas is governed by bringing a flexible portion of the outer wall into contact with the inner, the degree of contact determining the rate of transmission of heat across. The bottom of the outer vessel is a corrugated plate of silver to the centre of which is soldered a copper block shaped to fit the contour of the inner vessel. The displacement of the diaphragm is controlled by a screw. Any desired rate of gas evolution can be obtained up to 10 litres per minute, and the delivery remains constant with any particular setting for several hours.

Mr. J. St. Vincent Pletts: The Davis-Pletts slide rule. In this slide rule the log-log scale and its reciprocal scale are related to the log scale in such a way that the numbers on the latter are the common logarithms of the numbers opposite them on the former. This enables full advantage to be taken of the properties of characteristics and mantissas for the purpose of indefinitely extending the non-recurring log-log scales. Further, scales for all the ordinary exponential, circular, and hyperbolic functions are arranged to read on the same log scale, so that any product or ratio of such functions can be obtained. Thus all such compound functions as $e^x \sin a$ and $\log a \cosh x$ can be obtained with a single setting of the slide and cursor, while every combination of the various functions is obtainable with two or more settings.

The National Physical Laboratory: (1) Radio-telegraphic direction-finding apparatus (Mr. R. L. Smith-Rose). This apparatus is of the type developed by Capt. Robinson, of the Royal Air Force. Instead of finding two positions of a receiving coil for which the signals have equal intensity, two coils at right angles are connected in series and rotated together until the signal strength is unaltered by reversing the connections of one of them. This gives the direction from which the signal is coming, and, therefore, the apparent bearing of the transmitting station. Differences between the apparent and the true bearing are found to occur, especially at night; these differences raise many interesting questions in connection with the transmission of electro-magnetic waves in radio-telegraphy. (2) Resistance alloy "omal" for electrical standards (Dr. W. Rosenhain, Mr. S. W. Melsom, and Mr. S. L. Archbutt). The material is of the type usually known as "manganin," and is an alloy of copper, manganese, and nickel. Prior to the war the product was supplied almost exclusively by Germany, and great difficulty was experienced by makers of scientific and ordinary measuring instruments in obtaining material suitable for their purpose from any other sources. The question was investigated at the laboratory, and as a result alloys were made and watched through the various processes that meet the requirements as regards temperature coefficient, constancy, resistivity, and secular change. The material is made in two types, one having a resistivity of 45 michrom-cm. and the other of 35 michrom-cm. Samples of the product are shown in various stages of manufacture in the form of cast ingots, rod, strip, and wire, together with micrographs and curves of temperature coefficient. (3) Relay for breaking moderately large electric currents (Dr. Guy Barr). The difficulties due to sparking at the contact of ordinary relays are avoided by causing the make-and-break to occur between mercury electrodes in an atmosphere of hydrogen. An iron core floating in mercury carries at its upper end a silica cup, also full of mercury. Connections are made to the mercury outside and inside the cup. A solenoid pulls the core and cup down and thus makes the contact; the current is broken by the core floating up so that the surface of the mercury is cut by the silica. The spark is sufficiently quenched to allow currents up to 20 amperes at 100 volts to be broken easily. The mercury remains clean. (4) Standard optical pyrometer (Dr. Kaye and Dr. Griffiths). This instrument has been designed with the view of facilitating the accurate measurement of high temperatures by the "disappearing filament" method. An image of the hot object is superimposed on the filament of the pyrometer lamp and the brightness matched by varying the current through the lamp. Monochromatic

red light is obtained by means of a filter-glass in the eyepiece. To enable the observer to check the permanency of the calibration of the pyrometer, two lamps are fitted which can be interchanged exactly in the field by a simple transverse motion. Each lamp is provided with fine adjustment in three mutually perpendicular planes. The use of the pyrometer for measuring the "black body" temperature of lamp filaments was demonstrated.

Dr. E. E. Fournier d'Albe: Latest form of the optophone. The optophone is an instrument which enables totally blind people to read ordinary printed books and newspapers. It is based upon the reflection of beams of rapidly intermittent light from the type on to a selenium preparation, which produces sounds in a telephone varying according to the shapes of the letters. The instrument shown was kindly lent by the National Institute for the Blind, London, where it is in daily use.

Dr. Leonard Hill: Recording kata-thermometer. This instrument gives a continuous record of the cooling power of the environment exerted on the surface of the bulb of the kata-thermometer, which is automatically kept at skin-temperature. Introduced into the bulb of the "kata," which is filled with alcohol, is a coil of wire with a large temperature coefficient of resistance. This coil forms one arm of a Wheatstone bridge, which is balanced when the coil is at a temperature of 36·5° C. An automatic device is used by which the current sent through the coil varies according to atmospheric conditions, so that the coil is kept at 36·5° C. The ammeter placed in series with the coil indicates the variations of current, and so the cooling power.

Sir J. J. Dobbie and Dr. J. J. Fox: Photographs of absorption spectra of alkaloids. The absorption spectra of the alkaloids are characteristic of the substance, and within certain limits may be used to distinguish the class of alkaloid. The bands obtained are the bands due to the unreduced part of the molecule of the alkaloid. Thus the bands of quinine, cocaine, and morphine are practically identical in position with those of 6-methoxyquinoline, benzoic acid, and catechol respectively. Emetine, cephæline, corydaline, laudanosine, and certain other alkaloids all give absorption spectra showing that they contain the unreduced catechol grouping. The photographs exhibited show that minute quantities of the alkaloid are sufficient to obtain the characteristic spectrum. Thus 0·3 milligram of strychnine suffices to detect and characterise this substance.

Mr. J. E. Barnard: The microscopic appearance of animal tissues in ultra-violet light. Certain animal tissues show marked differentiation of structure when illuminated by means of ultra-violet light. The image obtained is a fluorescent one, and the resulting colours or tints depend on differences of chemical constitution. Such images are often dissimilar from those resulting from staining reactions. The light-filter used is glass transparent to ultra-violet radiations, approximately 300–400 $\mu\mu$ wave-length, made by Messrs. Chance Brothers. This is combined with a quartz cell filled with a 20 per cent. solution of copper sulphate. The optical illuminating system is of quartz and the sub-stage quartz condenser of the "dark-ground" type. Apart from the biological interest of the method, the image so formed is of considerable value for testing the optical qualities of microscopic objectives, as the object so illuminated is a perfectly self-luminous one.

The Protozoological Laboratory, Rothamsted Experimental Station, Harpenden: The protozoan fauna of the soil. The Rothamsted experiments have demonstrated the presence in soil of an active protozoan fauna, and investigations are now in hand to ascertain the mode of life of the organisms and their effect on other soil inhabitants, especially bacteria. For this purpose daily counts are made of bacteria and of protozoa in a natural field soil, discriminating between active and encysted protozoa and between various kinds of amœbæ and of flagellates. Typical forms were shown, including an interesting binucleate amœba. The daily counts were set out on curves which show a remarkable periodicity in the case of the flagellate *Oicomonas termo*, Martin, and an inverse relationship between the numbers of active amœbæ and of bacteria.

Prof. Walter Garstang: Some remarkable Gastropod larvæ (Echinospira). *Echinospira diaphana* was discovered at Messina and described in 1853 by Krohn, who showed it to be the pelagic larva of Lamellaria. It has two shells, one inside the other. The outer is cast aside at metamorphosis. A complete series of a related species from Plymouth was exhibited, where the metamorphosis for the first time has been observed. Diagrams of related species illustrated the larval evolution of the group and its remarkable parallelism to the development and evolution of Ammonites.

The Hon. H. Onslow: Abraxas grossulariata (the magpie or currant moth) and its varieties, showing mode of inheritance. There are many varieties of the magpie moth, which are inherited according to the well-known laws first formulated by Mendel. The black pattern of the type-form usually shows dominance over the other varieties. The patterns of the pale variety, *lacticolor*, and of the melanic variety, *varleyata*, are combined to produce a new form, *exquisita*. As is well known, the *lacticolor* pattern is linked to the female sex, and in the same way the radiated variety, *actinota*, is linked to the male sex.

Dr. John Rennie: Preparations showing various aspects of acarine disease in hive-bees. The specimens exhibited were (1) the mite, *Tarsonemus Woodi*, Rennie, which is the causal organism in acarine disease in the honey-bee; (2) infested tracheæ of bees, showing *T. Woodi* in all stages of development; and (3) tracheæ showing pathological development of chitin in the areas of infestation. (4) Other mites found in association with hive-bees, including one other species of Tarsonemus. The disease, apparently restricted to the British Isles, first appeared in 1902. Affected bees usually lose their power of flight.

The Zoological Department, King's College (University of London): Reconstruction models and drawings made by Dr. F. J. Wyeth, illustrating the development of the auditory apparatus and adjacent structures in the New Zealand Tuatara (Sphenodon). The models were made of wax plates 1 mm. in thickness, each plate representing an enlarged microscopic section, the different systems of organs being distinctively coloured. The drawings were for the most part made from the models to illustrate Dr. Wyeth's memoir on the development of the auditory apparatus, etc., in Sphenodon, communicated to the Royal Society by Prof. A. Dendy.

Department of Zoology, British Museum (Natural History): Life-history of the common eel (Mr. C. Tate Regan). The researches of Dr. J. Schmidt have shown that the common eel or fresh-water eel (*Anguilla vulgaris*) of Europe breeds in the Atlantic south-east of Bermuda. A series of larvæ, 9–60 mm. long, from the middle and western North Atlantic was exhibited; these growing larvæ have long and slender pointed teeth. The metamorphosis into the elver, or young eel, was shown by a photograph. Models illustrated the changes in the adult eel when it migrates to the ocean and becomes mature.

Zoological Laboratory, Imperial College of Science, South Kensington, S.W.: (1) Embryonic calcareous structures of the lantern of the sea-urchin, *Echinus miliaris* (Mr. Devanesen). The calcareous parts of the lantern, with the exception of the teeth, arise as tri-radiate spicules. While the jaws, the epiphyses, and the compasses each make their first appearance as a pair of spicules, the rotulæ alone arise from single spicules. Each tooth is made up of two adjacent vertical rows of rectangular lamellæ which afterwards fuse together. (2) The spermatogenesis of the louse, *Pediculus corporis* (Mr. H. G. Cannon). The somatic chromosome number in both sexes is twelve, but spermatogonial mitotic figures show only six, and there is evidence that these are double. There is only one spermatocyte division, which is extremely unequal, leading to the separation of a minute polar-body-like cell which degenerates. It is this division which was exhibited.

Royal Botanic Gardens, Kew: Abnormal development of lime-tree branches due to the presence of mistletoe (*Viscum album*, Linn.). Large and small swellings often occur on the branches of lime-trees infested with mistletoe, and there can be little doubt that they are due to the presence of the parasite, although on the larger swellings mistletoe is weak and sometimes difficult to find, while on small swellings, or where very little abnormal increase in girth is noticeable, mistletoe may be very vigorous. From the presence and character of the dead haustoria in the older parts of the large swellings it is apparent that healthy mistletoe was present at an earlier date. Canker, however, occurred, whereby the mistletoe became insecure and was eventually torn away by the wind. Vigorous new aerial branches did not appear, but buds and haustoria in the bark continued to grow, and the affected part of the lime branch developed at an abnormal rate, the consequent thickening of the bark probably inhibiting any strong aerial growth of the parasite.

Dr. W. Bateson: Variegated prothallia of a fern. The variegated fern, *Adiantum cuneatum* var. *variegata*, produces prothallia of which many are green and some variegated. From these arise ferns which may be green, variegated, or white. Apparently segregation here occurs in haploid tissue.

Mr. Franklin Kidd: Application of cold-storage and gas-storage to English apples. The Food Investigation Board has been investigating the possibilities of the cold-storage method and of a new method known as "gas-storage" in application to the English apple crop. Improved methods of apple storage are required in order to bring the home-grown apple into successful competition with imported apples throughout the winter season. In cold-storage the apples are kept just above freezing point. The method is costly. In "gas-storage" the apples are held in a gas mixture created and maintained by their own respiratory activity, no machinery being required. This method is cheaper.

Dr. W. Lawrence Balls: Portable cotton-sorting mechanism. The "sorter" mechanism is designed to analyse a collection of such fibres as cotton-hairs by distributing them on a collecting surface in the order of their individual lengths, thus enabling the frequency distribution of length to be plotted. The instrument shown was re-designed from the original automatic form in order to provide a portable pattern convenient for the use of cotton-growers and agricultural experiment stations abroad.

Dr. A. Smith Woodward: Fossil fishes from the Old Red Sandstone of Shetland. This is part of a collection lately made by Mr. T. M. Finlay, of the University of Edinburgh, and is important as including well-preserved specimens of a Palæoniscid fish related to the Carboniferous Rhadinichthys. Scales of a similar Palæoniscid are already known from Upper Devonian formations in North America and Antarctica.

Dr. F. A. Bather: Some questionable fossils. (1) Tubular quartzite of Cambrian age from Sweden and of Lower Devonian age from the Eifel. Are the structures produced by worms or by ascending air-bubbles? (2) Echinoderm remains of Permian age from Timor. Are they spines of sea-urchins or bases of crinoids? (3) Horned Trilobites of Middle Devonian age from the Eifel. What, if any, was the use of the horns?

Mr. J. Reid Moir: A series of ochreous flint implements, cores, and flakes of Early Chellean (Palæolithic age) from the base of the Cromer Forest Bed deposits. The specimens exhibited were collected from a limited area of foreshore exposed at low water at Cromer, Norfolk. The series included implements of Early Chellean forms, such as have been found hitherto in river-terrace gravels, together with rostro-carinates, choppers, scrapers, points, cores, and a large number of flakes. If the specimens are assigned correctly to the base of the Cromer Forest Bed, then the earliest Palæolithic cultures are referable in East Anglia to the Upper Pliocene deposits.

Mr. George H. Gabb: The original portrait of Galileo by D. Tintoretto, in oil, painted about 1605–7, when Galileo was from forty-one to forty-three years of age. This portrait is of great historic interest as probably the earliest original existing portrait of Galileo, a somewhat earlier one by Santè di Tito having been lost. At the time D. Tintoretto painted the portrait Galileo was master of mathematics at Padua, which is indicated by the inscription on it, "Gallileus Gallileus Mathus." This was some years before he began the great astronomical discoveries by means of the telescope which consolidated the theory of the Copernican system and immortalised his name. A small engraving by Schiavoni was made of this portrait about 1812.

University and Educational Intelligence.

CAMBRIDGE.—The Adams prize has been awarded to Dr. W. M. Hicks, St. John's College.

It is proposed to form an advisory committee on geodesy and geodynamics to make provision for study and research in geodesy, including arc measurements, primary triangulation, precise levelling, and gravity determinations; also for geodynamics and tidal phenomena. It is hoped to take the first active step towards the foundation of a school of geodesy and geodynamics which would eventually meet the practical needs of the surveys of the Empire. The advisory committee would be largely nominated by outside bodies, and both the Hydrographer of the Navy and the Director-General of the Ordnance Survey would be represented on it. Further steps in organisation await the appointment of a prælector in geodesy by Trinity College.

LONDON.—The following new appointments have been made at University College:—Mr. T. A. Brown, senior lecturer in pure mathematics for the session 1921–22, and Dr. Percy Stocks, medical officer in connection with the department of applied statistics and eugenics (this appointment has been instituted by means of a grant made by the London County Council).

Sir William Tilden will deliver three public lectures at University College on "The History of Chemistry in the Nineteenth Century" on Fridays, May 27 and

June 3 and 10, at 5 p.m. The chair at the first lecture will be taken by Prof. J. Norman Collie.

MANCHESTER.—The council has instituted a new chair in the Faculty of Commerce, and appointed Mr. G. W. Daniels as professor of commerce and administration as from September 29 next. Dr. Albert Ramsbottom has been appointed professor of clinical medicine. The following appointments have also been made by the council:—Senior lecturer in economics, Mr. T. S. Ashton; lecturer in histology, Miss Ruth Fairbairn; assistant lecturers in physics, Dr. J. C. M. Brentano and Mr. H. Lowery; and assistant lecturer in metallurgy, Mr. Hugh O'Neill.

PROF. EINSTEIN will deliver this year's Adamson lecture of the University of Manchester on some day during the first week in June. He will afterwards visit King's College, London, and other institutions which approached him after he had arranged to go to Manchester.

THE open competitive examination for assistant examiners in the Patent Office will begin on Tuesday, July 26, instead of on July 12 (as stated in the printed regulations), and will last until Saturday, July 30. Any candidate who has attained the age of twenty on July 26, and has not attained the age of twenty-five on July 12, will be regarded as eligible in respect of age to compete on this occasion.

WE learn from *Science* that at a recent meeting of some of Sir William Osler's students an Osler Memorial Association was formed for the purpose of founding an Osler memorial lectureship in the University of California, which will provide for an annual lecture on a scientific subject. The expense will be met by a yearly assessment of the members of the association. Dr. John M. T. Finney, Baltimore, has accepted an invitation to deliver the first lecture.

THE Salters' Institute of Industrial Chemistry (Salters' Hall, St. Swithin's Lane, E.C.4) invites applications for a limited number of fellowships, value 250*l*. per annum, from those who by October next will have completed three years' training in chemistry and seek an industrial career. Full particulars of training and war service (if any) of candidates should reach the director of the institute before June 18.

THE council of the British Medical Association is prepared to receive applications for an Ernest Hart memorial scholarship, of the value of 200*l*. per annum, for the study of some subject in the department of State medicine, and for three research scholarships, each of the value of 150*l*. per annum, for research relating to the causation, prevention, or treatment of disease. Each scholarship is tenable for one year, commencing on October 1, but a scholar may be re-elected for a period not exceeding two additional terms. A number of grants for assisting research will also be awarded, preference being given to members of the medical profession and to applicants who propose to investigate problems directly related to practical medicine. Applications for scholarships and grants, which must be made not later than June 25, should be accompanied by testimonials, including a recommendation containing a statement as to the probable value of the work to be undertaken, from the head of the laboratory, if any, in which the applicant proposes to work. Forms and further particulars can be obtained from the Medical Secretary of the British Medical Association, 429 Strand, W.C.2.

THE eighth annual report on the industrial fellowships of the Mellon Institute in the University of Pittsburgh directs attention once again to the scheme for promoting industrial scientific research which was initiated by the late Prof. Robert Kennedy Duncan in the University of Kansas in 1907 and in the University of Pittsburgh in 1911. The principles upon which the scheme is based, which were described in a report by Mr. T. Ll. Humberstone published some years ago by the Board of Education, should by this time be well known in this country. Although not "commercial" in spirit, the Mellon Institute has been able to render a great national service by demonstrating to American manufacturers that industrial research is a paying proposition. The number of industrial fellowships in operation in the institute is now forty-eight, and the money contributed by industrial firms in the last ten years amounts to 1,534,273 dollars. A considerable number of fellowships have been established by groups of firms, and the report points out that some of the larger multiple fellowships are now so well established and so distinctive in their fields of inquiry that they are not uncommonly regarded as independent organisations. This development will, no doubt, require watching in future. Several experimental plants have been set up in connection with the institute. Recent subjects for investigation include magnesia products, fruit beverages, asbestos, and refractories. The Kennedy Duncan system of industrial fellowships has now been thoroughly tested and its fundamental principles remain unshaken; and it may well be asked why, with so much public money freely spent in this country on applied scientific research, this admirable method of establishing a link between the universities and industry has not been given a trial.

THE list of the summer courses in England and Wales prepared by the Special Inquiries Office of the Board of Education for the use of education authorities and teachers has just been issued. The information provided is in tabular form under the following headings:—Authority responsible for course; place; date; fee; subjects of instruction; address for further particulars; and remarks. In the eastern counties of England there will be a course on the origin and development of the physical geography of Europe, map construction, anthropogeography, historical, political, and economic geography at Cambridge, and another on the principles and practice of horticulture at Chelmsford. At the South-Eastern Agricultural College, Wye, lectures and demonstrations will be given illustrating the teaching of chemistry, botany, mycology, and entomology applied to everyday life. In the Midland Counties courses on teaching method as applied to geography will be given at Nottingham; and there will be lectures and conferences on the teaching of numerous subjects, including geography and science, at Oxford. In the south-western area courses in geography, chemistry, mathematics, physics, and psychology will be held at Exeter; while at Weston-super-Mare the subjects include experimental science, botany, rural science, and hygiene. At both places the courses will be designed to fit teachers for continuation-school work. In the northern counties lectures on oceanography and fisheries will be given at Barrow-in-Furness. At four places in Wales there will be courses in science subjects. At Amman Valley County Intermediate School there will be a course on mine surveying, and at Madryn Castle Farm School one on school gardening and rural science. At Cardiff courses will be given in pure and applied science, particularly in various branches of engineering, and at Bangor on the teaching of geography and regional survey work. The table of courses can be obtained from H.M. Stationery Office or from E. Ponsonby, Ltd., 116 Grafton Street, Dublin (4*d*. net).

Calendar of Scientific Pioneers.

May 19, 1786. Carl Wilhelm Scheele died.—Pre-eminent as an experimental investigator and chemical discoverer, Scheele worked as an apothecary in various towns in Sweden, devoting his leisure to chemistry. Included among the many substances he discovered are chlorine, ammonia, oxygen, and several acids.

May 20, 1793. Charles Bonnet died.—A well-known naturalist of Geneva, Bonnet made researches on parthenogenesis, the respiration of insects, and the use of leaves. He also published works on psychology.

May 20, 1880. William Hallowes Miller died.—A fellow of St. John's College, Miller from 1832 to 1870 was professor of mineralogy at the University of Cambridge. He developed a system of crystallography adapted to mathematical calculation.

May 21, 1894. August Adolf Eduard Eberhard Kundt died.—A student under Magnus, Kundt in 1888 succeeded Helmholtz as professor of experimental physics and director of the Berlin Physical Institute. His most successful work related to sound, light, and magneto-optics.

May 22, 1666. Gaspar Schott died.—To Schott, Guericke, and Johann Sturm belongs the credit of reviving the study of the physical sciences in Germany after the Thirty Years' War. Schott was educated in Italy as a Jesuit, but afterwards taught at Wurzburg. His "Mechanica—hydraulica—pneumatica" (1657) contains the first description of the air pump.

May 22, 1868. Julius Plücker died.—A mathematician and physicist of Bonn, Plücker extended analytical geometry, and was known for his discovery of magneto-crystallic action, and for his researches on spectroscopy and the electric discharge in rarefied gases.

May 23, 1857. Auguste Louis Cauchy died.—Covering the whole field of mathematics and mathematical physics, the work of Cauchy is noteworthy for the rigorous methods he introduced. He was a professor at the Ecole Polytechnique.

May 23, 1894. George John Romanes died.—After early work on the nervous and motor systems of the Echinodermata Romanes turned his attention to such questions as mental evolution in animals. He was an intimate friend of Darwin, and did much to popularise his views.

May 23, 1895. Franz Ernst Neumann died.—Neumann was born in 1798, and from 1829 to 1876 was professor of mineralogy and physics in the University of Königsberg. He did important work on the dynamical theory of light and on the mathematical theory of electrodynamics.

May 24, 1543. Nicolas Copernicus died.—Born at Thorn in 1473, Copernicus, or Koppernigk, was the fourth child of a merchant. After studying at Cracow, Bologna, Padua, and Ferrara, Nicolas, through his uncle the Bishop of Ermland, became a canon of Frauenburg Cathedral. Later on he was administrator of the diocese. Among his great contemporaries, Luther, Erasmus, Leonardo da Vinci, and Paracelsus, Copernicus is the representative of the reformers of astronomy. All his leisure was given to observation; his "De Revolutionibus" is the result. The first printed copy of this work was placed in the hands of Copernicus when he was dying. Dedicated to Pope Paul III., many years afterwards it was placed upon the Index.

May 24, 1837. Karl Ernst Adolf von Hoff died.—The friend of Werner and Goethe, Hoff is known to geologists for his "History of the Changes on the Surface of the Earth" (1822–41). E. C. S.

Societies and Academies.

London.

Linnean Society, April 21.—Dr. A. Smith Woodward, president, in the chair.—Prof. R. **Newstead**: Some observations on the natural history of the Upper Shiri River, Nyasaland. The common types of the flora and fauna were discussed. The flora was dealt with under three sections:—(1) The river and its banks, (2) the open "dambo" or savannah, and (3) the forest. Dealing with the insects, special reference was made to a highly protective species of Mantis (*Taracodes perloides*) and the common tsetse-fly of the country (*Glossina morsitans*), the latter being the chief factor in the dissemination of sleeping sickness in man. Seventy-eight species of birds were collected; among these a new species of flycatcher (*Erithrocerus nyasae*); and large flocks of the rare lorikeet (*Agapornis lillianae*) were observed.

Faraday Society, May 9.—Prof. A. W. Porter, president, in the chair.—E. K. **Rideal** and U. R. **Evans**: The problem of the fuel-cell. Fuel-cells may be classified as:—(1) Direct fuel-cells burning solid fuel. These suffer from current polarisation due to the low velocity with which carbon enters into electrodic reactions. (2) Semi-direct fuel-cells burning gaseous fuel. These suffer usually from current polarisation due to the difficulty of keeping the electrode material saturated with gas. Mond and Langer overcame this, but in doing so used so much platinum that their cell became far too expensive for practical use. An attempt to use nickel instead of platinum as the substratum of a gas-electrode was unsuccessful. (3) Indirect cells of (*a*) oxidation-reduction type. These suffer from not only (i) *current* polarisation, dependent on the electrode area, but also (ii) *time* polarisation, dependent on the cell *volume*. This second kind of polarisation is economically most important, but has been overlooked by some workers. Some fresh cells of this type were tested, but proved unsuitable. (*b*) Metal anode type. Zinc appears unsuited, but preliminary experiment with different cells (both hot and cold) in which tin was the active element gave results which seemed promising.—L. F. **Knapp**: The solubility of small particles and the stability of colloids. A theoretical paper in which Ostwald's relation between the solubility and size of particles is modified for the case where the particles are electrically charged. An attempt is made to explain the connection between the stability of colloids and the charge carried by their particles.

Edinburgh.

Royal Society, May 2.—Prof. F. O. Bower, president, in the chair.—Dr. Dawson **Turner** and Mr. D. M. R. **Crombie**: Behaviour of an electrified pith ball in an ionised atmosphere. This communication concerns a delicate method of demonstrating the ionised atmosphere surrounding flames and hot bodies by means of a pith ball suspended from the knob of a charged Leyden jar. The effectiveness of various sources of ionisation was demonstrated, and the directive influence of the charged Leyden jar shown. The conclusions arrived at were:—(1) A charged pith ball can serve as a very delicate indication of the electrical condition of its surroundings. (2) The ions are concentrated along the straight line joining the centre rod of the charged jar and the source of ionisation. (3) The ions tend to be carried upwards by convection currents. (4) The ionisation of the atmosphere does not depend upon the luminous or actinic intensity of the flame, but is associated with a radiation of longer wave-length. (5) The effect

upon the electrified pith ball appears to be independent of the nature of its charge.—Dr. R. **Kidston** and Prof. W. H. **Lang**: Old Red Sandstone plants, showing structures from the Rhynie Chert Bed, Aberdeenshire. Part iv.: Restorations of the vascular cryptogams, and discussion of their bearing on the general morphology of the Pteridophyta, and the origin of the organisation of land plants. Restorations of the four plants, *Rhynia Gwynne-Vaughani, R. major, Hornea Lignieri*,, and *Asteroxylon Mackiei*, are given. A few additional features, supplementary to the descriptions in preceding papers of the series, are described. The hemispherical projections of *Rhynia Gwynne-Vaughani* are shown to have originated underneath stomata. A comparison is made between them and certain intamescences in existing plants. Areas of necrosis and marked wound-reactions of the tissues around them are described for both species of Rhynia. The apex of a stem of *R. major* is figured. The discussion summarises the authors' views on the bearings of the facts described in the Parts i.–iv. on problems in plant-morphology. Part v.: The Thallophyta occurring in the peat-bed; the succession of the plants throughout a vertical section of the bed, and the conditions of accumulation and preservation of the deposit. The Thallophyta found in the silicified peat are described. The most abundant are fungi represented by hyphæ of the mycelium, and vesicles or resting-spores borne on this. With the exception of one specimen, the hyphæ were non-septate, and the fungi are regarded as belonging to the Phycomycetes. A number of form-types are described; the species distinguished are *Palaeomyces Gordoni, P. Gordoni* var. *major, P. asteroxyli, P. Horneae, P. vestita, P. Simpsoni*, and *P. agglomerata*. The possibility of there being a symbiotic (mycorrhizal) relation between certain fungi and the vascular cryptogams is discussed; there is no conclusive evidence in favour of this. The majority of the fungi in the Rhynie peat were certainly living as saprophytes. Bacteria were doubtless present in abundance, but are difficult to distinguish in the granular matrix. A representative of the Schizophyta, a filamentous organism with the small protoplasts preserved, is named *Archaeothrix oscillatoriformis*, and compared with Beggiatoa and Oscillatoria among existing plants. Scattered remains of an alga, the vegetative structure of which presents a number of resemblances to existing Characeæ, are described under the name *Algites (Palaeonitella) cranii*. Two fragments belonging to an organism with the characteristic structure of Nematophyton are described as *N. Taiti*. The specimens show the structure of the peripheral region, which in specimens previously described has not been preserved. The succession of the plants throughout a section of the Chert Bed as exposed *in situ* is followed, and the conditions of formation of the Rhynie deposit are discussed. On grounds mainly of resemblances presented by Asteroxylon to *Tharsophyton (Lycopodites) Milleri*, the Rhynie Chert Bed is allocated to the Middle Old Red Sandstone age.

PARIS.

Academy of Sciences, April 25.—M. Georges Lemoine in the chair.—C. **Guichard**: Triply indeterminate systems of right lines and their conjugates with respect to a linear complex.—L. **Cuénot**: The different modes of regeneration of the antennæ in *Carausius morosus*.—C. **Nicolle** and A. **Cuénod**: New acquisitions in the experimental study of trachoma. An account of results obtained in experiments on apes and rabbits.—I. **Tarazona**: Observation of the annular eclipse of the sun on April 7, 1921, at the astronomical observatory of the University of Valencia (Spain). Comparison of the observed and calculated times of contact.—P. **Fox**: Measurements of stellar parallax at the Dearborn Observatory. The table giving the parallax of twenty-four stars is based on photographic observations with the 48-cm. equatorial.—A. **Leduc**: The principle of equivalence and reversibility.—H. **Buisson** and C. **Fabry**: The displacement of the solar lines under the action of the gravitational field. The differences observed between the lines of the solar spectrum and those of the arc in vacuum can be perfectly interpreted by the following hypotheses: the pressure in the reversing layer is small, and consequently the effect of the pressure can be neglected, and the Einstein effect is the only cause of the displacement of the lines of the solar spectrum.—Mme. P. **Curie**: The γ radiation and the evolution of heat from radium and mesothorium. The heat evolved is measured by an ice calorimeter with a capillary tube, one division of which corresponds to about 0·03 calorie. A method for the determination of the relative quantities of radium and mesothorium in a sealed tube can be based on the calorimetric measurements, and it may also be possible to determine the age of the specimen by observations with time-intervals of several months.—Mlle. Irène **Curie**: The atomic weight of chlorine in some minerals. Three minerals were examined, a Canadian sodalite, a Norwegian apatite containing chlorine, and a salt from Central Africa. The hydrochloric acid prepared from these minerals was converted into barium chloride, and comparative experiments were made on the silver chloride obtained from these and from ordinary pure barium chloride. With the sodalite and the apatite the differences observed were of the same order as the experimental error; in the case of the salt the atomic weight found was 35·60. This difference was proved not to be due to the presence of bromine or iodine, and further experiments with this material will be carried out.—M. **Laporte**: The measurement of the mobility of gaseous ions by the toothed-wheel method. The mobility of gaseous ions has been measured by a method based on that used by Fizeau for the determination of the velocity of light. Some preliminary results are given.—G. **Contremoulins**: The protection against X-rays of persons other than the operator and patient. The effects of modern X-ray tubes can be felt outside the operating-room, and in thickly populated districts may be a source of danger. Experiments are described bearing on the precautions required to prevent the rays penetrating beyond the operating-room.—A. **Dauvillier**: The working of the Lilienfeld tube.—C. **Matignon**: The principles of some new methods applicable to the determination of molecular weights. The utilisation of chemical equilibria for the measurement of molecular weights.—L. **Guillet**: The tempering of brasses containing tin.—M. **Pierrat**: The solubility of various potassium salts in mixtures of water and alcohol. Alcoholic solutions of varying strength in alcohol of the salts examined (potassium bitartrate, perchlorate, chloroplatinate, fluosilicate, and cobaltinitrite) were prepared by prolonged shaking of the salt with the mixture, the alcohol removed by evaporation in a current of dry air, the liquid made up to its original volume with water, and the concentration of the salt determined by the electrolytic conductivity method. Solubilities for each of the above salts are given for six different concentrations of alcohol.—P. **Dumesnil**: The acid ethyl diethylmalonate.—M. **Randoin**: Contribution to the study of the globular silica representing the flint clay to the south of the Paris basin.—M. **Delépine**: The active racemic com-

pounds. The author regards a crystalline structure as racemic if it is composed of equal numbers of dextrorotatory and lævorotatory molecules. The optical activity is only an accessory phenomenon depending on the nature of the molecules of each configuration, and is zero in the particular case of simple enantiomorphs.—J. **de Lapparent**: The episodic character of the layers of carboniferous limestone in the Boulonnais and the dolomitisation of certain of them.—S. **Stefanescu**: Some morphological characters of the crown of the molars of mastodons and elephants.—R. **Souèges**: The embryogeny of the labiates. The development of the embryo in *Mentha viridis*.—A. **Goris** and C. **Vischniac**: The alkaloids of valerian. The authors' results confirm those of Waliszewski and Chevalier. Valerian root contains two alkaloids, chatinine (soluble in ether) and valerine (insoluble in ether, but soluble in chloroform). The proportions found in the root are very small, and, as their physiological action is slight, these substances probably have no bearing on the therapeutic action of the valerian.—J. **Politis**: The mitochondrial origin of the anthocyanic pigments in fruits.—E. **Licent**: The structure and evolution of the nucleus in the meristem cells of some Euphorbiaceæ.—R. **de Litardière**: Remarks on the chromosomic processes in the diploidic nuclei of *Podophyllum peltatum*. The author's observations on the evolution of the somatic chromosomes of *P. peltatum*, given in detail, are not in accord with those of Overton.—A. **Desgrez** and H. **Bierry**: Food rations and vitamins.—A. **Lumière**: Surface tension and the anaphylactic shock. Reply to the criticisms of W. Kopaczewski.—A. **Vandel**: The regeneration of the genital glands in Planaria.—A. **Labbé**: The adaptive modifications of *Dunaliella salina*.—A. **Magnan**: The variation in weight of the lowering and lifting muscles according to the extent of the wing-surface in birds.—S. and A. **Mayer**: The fundamental organic substance of amylopectin. The amylopectin was separated by electrodialysis from a starch solution. Its chemical and physical properties are compared with those of the amylose solution obtained in the process of preparation.—E. **Roux**: Some remarks on the action of light and heat radiations in heliotherapy.

Diary of Societies.

THURSDAY, MAY 19.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—E. Law: The Architecture and Art of Hampton Court Palace: I. In Tudor Times.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital, Paddington), at 4.30.—Dr. H. H. Dale: Anaphylaxis and Immunity.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—R. E. Fry: Architectural Heresies of a Painter.

ROYAL SOCIETY OF MEDICINE (Dermatology Section) (Annual General Meeting), at 5.

INSTITUTION OF MINING AND METALLURGY (at Geological Society), at 5.30.—E. H. Clifford: Scheme for Working the City Deep Mine at a Depth of 7000 ft.—The following Papers will be submitted for Discussion:—F. P. Caddy: Stope Measuring at the Passagem Mine of the Gold Mines of Ouro Preto, Ltd.—J. A. P. Gibb: Notes on Some Useful Alignment Charts.

CHEMICAL SOCIETY (Informal Meeting), at 8.

RÖNTGEN SOCIETY (in Physics Lecture Theatre, University College), at 8.15.—Prof. A. V. Hill: Electrical Instruments and Phenomena in Physiology (Fourth Silvanus Thompson Memorial Lecture).

FRIDAY, MAY 20.

ROYAL SOCIETY OF MEDICINE (Otology Section) (Annual General Meeting), at 5.—F. J. Cleminson: Sinusitis in Children.
JUNIOR INSTITUTION OF ENGINEERS, at 8.—A. Arnold: Liquid Fuels.
ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.1), at 8.15.—Lt.-Col. H. Kirkpatrick: Trachoma.—C. H. Marshall: New Method of Treatment of Human Trypanosomiasis. —C. França: An Early Portuguese Contribution to Tropical Medicine.
ROYAL SOCIETY OF MEDICINE (Electro-Therapeutics Section) (Annual General Meeting), at 8.30.—Discussion: The Stomach.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Prof. E. H. Starling: The Law of the Heart.

SATURDAY, MAY 21.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Legge: Gnosticism and the Science of Religions. I.

MONDAY, MAY 23.

VICTORIA INSTITUTE (at the Central Hall, Westminster), at 4.30.—Rev. Dr. W. St. Clair Tisdall: The Date of Daniel.
INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting) (at Chartered Institute of Patent Agents), at 7.
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.
ARISTOTELIAN SOCIETY (at University of London Club), at 8.—Very Rev. Dean Rashdall and Others: Discussion on Dr. Inge's "The Idea of Progress."
MEDICAL SOCIETY OF LONDON (at 11 Chandos Street, W.1), at 8.—General Meeting.
ROYAL SOCIETY OF MEDICINE (Odontology Section) (Annual Meeting), at 8.—J. H. Mummery and G. J. Harborow: A Composite Odontome.—A. T. Pitts: The Prophylactic Extraction of the Third Molars.
ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Mrs. Rosita Forbes: Across the Libyan Desert to Kufara.
MEDICAL SOCIETY OF LONDON (at 11 Chandos Street, W.1), at 9.—Lord Dawson of Penn: The Colon and Colitis (Annual Oration).

TUESDAY, MAY 24.

INSTITUTION OF GAS ENGINEERS (at Institution of Civil Engineers), at 10 a.m.
ROYAL HORTICULTURAL SOCIETY (at Chelsea), at 3.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—E. Clodd: Occultism: Its Origin and Development.
LINNEAN SOCIETY, at 3.—Anniversary Meeting.
ROYAL STATISTICAL SOCIETY (at Surveyors' Institution), at 5.15.—G. Udny Yule: The Time-correlation Problem, with Especial Reference to the Variate-difference Method.
ROYAL SOCIETY OF MEDICINE (Medicine Section) (Annual General Meeting), at 5.30.—Dr. C. Riviere and Others: Discussion on Artificial Pneumothorax.
ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—The Secretary: Report on the Additions to the Society's Menagerie during the month of April, 1921.—Dr. C. F. Sonntag: The Comparative Anatomy of the Tongues of the Mammalia. IV. Families 3 and 4. Cebidæ and Hapalidæ.—R. Broom: Some New Genera and Species of Anomodont Reptiles from the Karroo Beds of South Africa.—R. I. Pocock: The External Characters of some Species of Lutrinæ (Otters).—Dr. C. W. Andrews: Note on the Skull of *Dinotherium giganteum* in the British Museum.
ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—(Technical Meeting.) Scientific Aspects of Studio Lighting.—L. Gaster: The Selection and Use of Illuminants for the Studio.—J. C. Elvy: Illumination Problems in Kinematography.—J. W. P. Walsh and H. Buckley: Methods of Light Distribution.—I. G. Priest: A Possible Standard of White Light.

WEDNESDAY, MAY 25.

INSTITUTION OF GAS ENGINEERS (at Institution of Civil Engineers), at 10 a.m.
ROYAL HORTICULTURAL SOCIETY (at Chelsea), at 3.
GEOLOGICAL SOCIETY OF LONDON, at 5.30.—G. W. Lamplugh: The Junction of Gault and Lower Greensand near Leighton Buzzard (Bedfordshire).
INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) (at Institution of Mechanical Engineers), at 6.—C. F. Elwell and Others: Discussion on Long-Distance Wireless Transmission.
ROYAL MICROSCOPICAL SOCIETY (Leather Industries Section), at 7.30. —P. Hampshire: "Run" Pelts in Sweating Process of Dewoolling.
ROYAL SOCIETY OF ARTS, at 8.—Dr. C. M. Wilson: The War and Industrial Peace: An Analysis of Industrial Unrest.

THURSDAY, MAY 26.

INSTITUTION OF GAS ENGINEERS (at Institution of Civil Engineers), at 10 a.m.
ROYAL HORTICULTURAL SOCIETY (at Chelsea), at 3.
ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—E. Law: The Architecture and Art of Hampton Court Palace. II. In Stuart and Later Times.
ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Sir Alfred Ewing: The Atomic Process in Ferro-magnetic Induction.—C. D. Ellis: The Magnetic Spectrum of the β-rays excited by the γ-rays.—S. Datta: The Spectra of the Alkaline Earth Fluorides and their Relation to Each Other.—Dr. W. L. Balls: A Simple Apparatus for Approximate Harmonic Analysis and for Periodicity Measurements.—Dr. G. R. Goldsbrough: The Influence of Satellites upon the Form of Saturn's Ring.—Dr. H. Jeffreys: Certain Geological Effects of the Cooling of the Earth.—T. Kikuchi: The Moving Striations in a Neon Tube (title only).
INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital, Paddington), at 4.30.—Dr. J. A. Murray: Aims and Progress of the Experimental Study of Cancer.
INSTITUTION OF ELECTRICAL ENGINEERS (at Institution of Civil Engineers), at 6.
CONCRETE INSTITUTE (Annual General Meeting), at 7.30.

FRIDAY, MAY 27.

ROYAL SOCIETY OF ARTS (Indian and Colonial Sections), at 4.30.—Sir Charles H. Bedford: Industrial (including Power) Alcohol.
PHYSICAL SOCIETY OF LONDON (at University College), at 5.—The General Electric Co. (communicated by C. C. Paterson): A Method for the Micro-analysis of Gases by the Use of the Pirani Pressure Gauge.—H. Pealing: The Reflection of the K-ray Spectrum of Palladium from Fluorspar.—Sir W. H. Bragg: The Intensity of X-rays reflected by the Diamond.—Exhibits of Crystal Models, and of Photographs by the Duc de Broglie of Cathode Ray Spectra attendant on the production of X-rays.
INSTITUTION OF MECHANICAL ENGINEERS, at 6.—J. G. Graves: The World's Money System.
ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—A. Mallock: Elasticity.

SATURDAY, MAY 28.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Legge: Gnosticism and the Science of Religions. II.

The Use of Oil Fuel.

THE prolonged coal stoppage has given an impetus to the use of oil fuel for industrial purposes. Conditions were favourable to such a development, and circumstances have helped to expedite it. One may reasonably assume that the coal industry will suffer some permanent loss as a consequence of this step, since fuel consumers, having gone to the expense of adapting their plants for oil burning, are not likely to revert wholly to coal again, especially as by doing so they would be surrendering the advantage of possessing an alternative which business counsels them to retain in view of the unhappy frequency of labour troubles in our coal-fields.

Another aspect of the matter which will influence commercial men is the economies which accrue from replacing coal with liquid fuel. In comparing the two, availability of supplies and prime cost are, obviously, the first factors to be taken into account. As market quotations now stand they do not tell against oil as they used to do. Fuel oil seems to be in good supply, and at the current price of about 6*l.* to 6*l.* 10*s.* per ton is practically as cheap as coal when everything is considered. As two tons of oil have approximately as high a calorific value as three tons of coal, the greater heating power of the former goes far towards equalising the difference in cost. Nor is this comparison in heating properties merely an estimated figure; it has been established by actual test. Oil fuel is, likewise, much cleaner to handle than coal, and the labour costs of operating it are far lower—roughly, about five times less. With it steam can be raised more quickly, and the temperature of furnaces regulated with greater ease. By simply turning the tap of the atomising spray one man controls the fire in an oil-burning furnace, whereas the coal-fed furnace keeps several men employed in shovelling in fuel, levelling fires, and breaking up clinker. Oil does not require any ash-ejecting equipment, which means a saving in plant, nor is the inside of the furnace damaged by "slicers" and "prickers"—and that also effects a saving in working costs.

Oil had been growing in favour before the existing industrial crisis came along to give impetus to its adoption. The British Admiralty was amongst the earliest to investigate its possibilities and to employ it on a large scale. After a lengthy period of experimenting, a flotilla of oil-fired destroyers was added to our Navy in 1909. Since that date oil has been steadily replacing coal as the staple fuel of H.M. ships, until at the present time all our effective warships are oil burners. Most of those retained on the active list also use oil for such auxiliary purposes as cooking the food of the crew.

Prior to the introduction of liquid fuel into the service the Navy was an exceedingly good customer to South Wales. But it now makes only a negligible demand upon the product of the pits there, as will be seen from the fact that during the current financial year the Navy is spending about three times as much upon oil fuel as it is upon coal. For the Navy an oil-fuel flash-point of 175° F. has been adopted. In the mercantile marine the flash-point is 150° F.; and in the latter service there has been a considerable "turn over" from coal to oil fuel during the past couple of years. How serious a matter this may prove for the coal producer is shown by the fact that whereas a ship like the *Aquitania* used to take in 660 ten-ton truck-loads of coal each time she crossed the Atlantic, she now has accommodation for 7000 tons of oil instead. Upon the salt-water highways the future lies largely with the motor ship, which is making its appearance there in ever-growing numbers. Being Diesel-engined, craft of this type have no direct use for coal as a fuel, and every such vessel put into service means a lessening of the demand for the output of the collieries. Looking at the subject comprehensively, one can only arrive at the conclusion that the extending use of oil for fuel purposes constitutes an economic factor that is bound to have a considerable effect upon our coal-mining industry in the future.

The great problem in connection with oil fuel is that of supply. It has been estimated that the world has coal enough to last it for another five hundred years. Nobody can estimate how much oil we possess, for no one knows. So far as Great Britain is concerned, we now have to import most of our stocks of this fuel, and for the time being the supplies are equal to the demand. The shale oils obtained in various parts of the United Kingdom are nearly all suitable for fuel, but the yield is very limited. Hopes are entertained that the new field opened in the Fen district will eventually give large supplies, and it is reported that oil can be obtained there at a cost of 2*d.* per gallon, as compared with the 10*d.* per gallon for Scotch shale. Whether this hope will be fulfilled or not we must "wait and see." However, judging by prices quoted and reports from oil-producing centres abroad, supplies available appear to be sufficient for present requirements. How far they would be equal to meeting a greatly extended demand is quite another matter.

Education as a Science.

Education and World Citizenship: An Essay towards a Science of Education. By James Clerk Maxwell Garnett. Pp. x+515. (Cambridge: At the University Press, 1921.) 36*s.* net.

READERS of Mr. Garnett's papers in the *British Journal of Psychology* and elsewhere will open this stately volume expecting to find substantial fare, nor will they be disappointed. The book is full of vigorous reasoning and independent thought. It is written from a definite point of view, with a definite purpose, which is systematically followed, and it leads to clear-cut conclusions. Its aim is given in its title. It is an attempt to outline a provisional science of education. Mr. Garnett is impressed by the need for an accepted body of scientific principles which will make our educational thought and practice more coherent and efficient. He has therefore made an effort to supply the want, in the modest hope that his attempt may stimulate others to more successful endeavours. The result is one of the few recent discussions of educational theory which deserve to be taken seriously.

Unlike too many writers, Mr. Garnett knows what he means by a science of education. Science, he tells us, is "an organised body of connected facts graded according to their relative importance" (p. 196). Such a body of facts when complete constitutes the "endarchy of science," which is the world of experience scientifically interpreted —"the neat, trim, tidy, exact world which is the goal of scientific thought." This ideal shapes his conception of the science of education, which is a portion of the complete endarchy of science. It also determines the lines upon which he considers education should be organised in practice. The facts upon which a science of education must be based he borrows from psychology, for psychology enables us to formulate "the laws of thought" from which scientific methods of education can be logically deduced. But the aim of education which must synthesise its methods is not given us by psychology. It depends upon the aim of human life. Unfortunately, the latter aim is still uncertain. We may, however, provisionally define it in the light of such agreement as exists, and thus develop a tentative science of education which will be a first approximation to the truth, and may serve as a provisional guide in practice.

Mr. Garnett's pages are so full of matter that points in his argument may easily be overlooked; but, unless we are mistaken, we have in his conception of educational science one of the sources of the dualism which is the great weakness of his book. Speaking roughly, we may say that education as a normative science must interpret facts in the light of values; but Mr. Garnett gets his facts and his values from different quarters, and as a result they will not mix. His facts remain facts and nothing more, and his values either belong to a world apart from facts, or are merely facts of a certain kind. Thus a man's will is the most valuable thing about him (p. 138); but will is unforeseeable, and possesses no quality that characterises its owner except its strength (p. 291). On the other hand, a fact gains value simply by the frequency of its recurrence (p. 217). This dualism is apparent throughout Mr. Garnett's argument. His endarchy of science is essentially a world of facts as such, and preferably of physical facts. Thus it is only unwillingly that he speaks of the mind and its processes. He prefers to speak of the "comparatively simple material aspects of the brain" (p. 8). His first "law of thought," for example, states that, apart from the intervention of the will, our thought activity at any moment is determined "by the neurones that are excited by the degree of their excitement" (p. 66), which is a rather bold statement. The elements of our mental life are "neurograms"—that is, "low resistance paths among the neurones of the brain or among those of other portions of the nervous system" (p. 42). Our purposes, which recent experiment has shown to play so important a part in our thinking, become

parts of our "neurography," compounded of the neurograms of, say, ourselves, some action, and some future time (p. 144 *et seq.*). This failure to do justice to the significance of purpose is evident in the elaborate discussion of the organisation of thought (chap. xi.).

The same tendency to explain values in terms of facts is seen in Mr. Garnett's use of the phrase "æsthetic satisfaction" to "denote the pleasant feeling that results when the instinct of curiosity achieves its end" (p. 253), and in his description of religious faith as "action on an hypothesis with a view to its verification" (p. 307). More important is the effect of his preoccupation with the tidy, exact world of scientific facts upon his conception of the aim of education. "Every citizen ought to develop a tidy and perfectly integrated mind—a single endarchy of neurograms—which should correspond, so far as the time and effort available for his education and his own 'educability' permit, to the endarchy of science" (p. 313). These individual endarchies will vary according to the citizen's special activities in the life of the community; but in all cases they should centre in a single wide interest system. Education must, therefore, aim at the development of an appropriate single wide interest in the mind of each boy and girl. Schools should be so organised as to offer unified courses of training for different classes of individuals, distinguished mainly by the types of callings for which they are prepared.

Mr. Garnett, however, has too keen an interest in ethics and religion to remain entirely content with the endarchy of science. Hence on ethical grounds he holds that human souls are really free, and can influence neural activity by the exercise of will (p. 97). What exactly is meant by the will and how it is related to the soul and to the body does not seem very clear. But it is the principal factor in developing a single wide interest (p. 268). Such interests, indeed, centre in conscious purposes, and we even find the alarming statement that "the possessor of a single wide interest will tend always to be conscious of his supreme and dominant purpose" (p. 244). In an important chapter (chap. vii.) it is argued that strength of will is measured by *g*, the index of general ability, and that *g* can be increased by training. Indeed, the cultivation of strong wills by the formal training of attention is one of the chief ends of education (p. 332 *et seq.*). Again, the world of science is brought into relation with religion, and more particularly with Christianity. "The Christian account of the universe . . . completes the discovered part of the endarchy of science with an hypothesis concerning the hitherto undiscovered central essences, it does so . . . in a manner that enables the corresponding neurography to fulfil the conditions that have to be satisfied by the neurography of the typical citizen of a maximally efficient and progressive community" (p. 355).

This conception of the function of religion is suggestive in many ways, but it is another example of the loss which the deeper things of life must suffer in order to be fitted into the Procrustes bed of the neat and tidy endarchy of science; and, speaking generally, Mr. Garnett's effort to make room in his world of scientific facts for freedom and religion can scarcely be regarded as successful. His system of education is too cut-and-dried, too externally determined and bureaucratic to meet the deepest demands of human nature. It might give us industrious citizens, good officials, and scientific experts, but scarcely prophets, artists, and men of genius. For while a tidy and integrated mind is greatly to be desired, it is not, perhaps, the highest type of mind we know. As Dr. Rivers has recently reminded us, some degree of mental instability is probably a condition of great achievement in art and science, and gives strength to man's deep craving for religion.

It has been impossible in this review even to touch upon many of the important topics which Mr. Garnett discusses with marked ability and wide knowledge. We may mention, for example, his discussion of general ability, cleverness, and purposefulness. It is from no lack of admiration for his achievement that we have dwelt upon an apparent weakness in his argument. That weakness will, we fear, militate against the general acceptance of his special point of view. But he has done us no small service in giving us a book which treats the theory and practice of education in a thoroughly scientific spirit. It is this spirit which matters most, and the book will stimulate and encourage all who hold loose thinking and vague metaphor to be as pernicious in education as they are in any other field of thought.

Advances in the Study of the Yeasts.

The Yeasts. By Prof. A. Guilliermond. Translated and thoroughly revised in collaboration with the original author by Dr. F. W. Tanner. Pp. xix+424. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 33*s*. net.

OUR knowledge of the yeasts has made great strides within the past twenty years, and for this we have mainly to thank the classical

researches of Emil Chr. Hansen. It is now realised not only that many industrial concerns depend for their success on a maintenance of conditions favourable to the multiplication of the yeast plant, but also that new fields of interest are unfolded to biologists and students of medical research. A book such as this is a timely addition to our literature, for hitherto we have had to be content with books on the subject of yeasts which had a purely industrial bias. In Prof. Guilliermond's book the whole subject is treated in a comprehensive fashion, and the reader will be able to follow the advances in the subject from different points of view.

Prof. Guilliermond's "Les Levures" appeared in 1912, but the present book is not a mere translation of the French edition; it is rather a collaboration of Dr. Tanner with the author to produce an English work in which it would be possible to incorporate the new material which has appeared since 1912. The idea is a happy one, but it has its disadvantages from the point of view of the reader. Thus, in the first chapter, in which the morphology and development of yeasts are discussed, Prof. Guilliermond is referred to in the third person, with the result that he becomes both counsel and judge in the estimation of the value of his own researches. There is little doubt as to the value of his contributions, but some of the points that have been raised are of a controversial nature, and not such that all biologists can accept without supporting evidence from independent investigators. Such, for example, are the heterogamic copulation of yeasts, and the attitude adopted in regard to the nuclear structures of these bodies. Many statements are of an *ex parte* nature, and raise doubts in the reader's mind as to whether he has heard both sides of the question. Incidentally, Mr. Wager is referred to by the name of "Wagner" throughout this section of the subject.

There is a very useful chapter on the nutrition and physiology of yeasts, which concludes with an unexpectedly scanty account of the theories which have been advanced to account for the alcoholic fermentation they induce. This is disappointing, for, after all, alcohol is responsible for having brought yeasts to the forefront, and the subject is honeycombed with tunnels of investigation.

On the question of phylogeny it is not possible to share the writer's optimism that matters are now "more settled." It is well established that particular growths of micro-organisms may be side-tracked into exceedingly minute structures which can in such a condition multiply indefinitely, and apparently never emerge into any other forms. It is a common phenomenon in bacterial cultures, and the present reviewer can vouch for the appearance of the phenomenon among some of the higher bacteria. The probability that yeasts are side-tracked offshoots of modern fungi may not be great, but there is sufficient evidence to make this theory not untenable even if some recent work in this direction must be set aside on account of cultural impurities. The chapters on the practical methods that are adopted for the studying of yeasts are somewhat perfunctory. Undoubtedly the most valuable portion of the book is the short description which is given of all the yeasts known to science. The authors have done for yeasts what Migula in his "System der Bakterien" accomplished for bacteria. We are grateful to them for having accomplished this arduous work. Greater knowledge has resulted in slight changes in the classification, but in essentials no striking changes have been effected.

As a book of reference this publication will remain a standard for some time to come. A warning must, however, be given, due to our imperfect knowledge of the activities of micro-organisms. It must not be taken for granted that the discovery of a yeast in a particular medium *necessarily* credits or discredits it for changes that occur in that medium; nor does it follow that if a name is given to a supposedly new species that species has not been named before. We know that several species of bacteria have received each several names, and it is probable that we are suffering from the same malady in the investigation of the yeasts. This, however, is an irregularity which a general text-book cannot be expected to rectify. We can say in conclusion that this book ought to be in the hands of all those who are interested in yeasts either from the purely scientific or from the industrial point of view.

DAVID ELLIS.

Introduction to the Theory of Curves.

Plane Algebraic Curves. By Prof. Harold Hilton. Pp. xvi + 388. (Oxford: At the Clarendon Press, 1920.) 28*s*. net.

DURING the present century there has been a very considerable increase in the number of students of the calculus, and this increase has been accompanied by a change in the character and content of the text-books. In the latter half of last century a considerable section of works on the calculus dealt with the theory of higher plane curves, and students with a liking for geometry were often led on to a fuller study of that theory, as expounded, for example, in Salmon's well-

known treatise. The tendency in more recent times, however, has been so strong in the direction of physics that less and less space is given in text-books of the calculus to the theory of curves, and the number of students of the theory has probably decreased. But investigation and research have, nevertheless, been continuous, and, now that Salmon's treatise is not readily accessible, even if it were abreast of modern developments, the need for a good introduction in English to the theory of curves has become clamant; such an introduction is to be found in Prof. Hilton's book.

A reader of the book is supposed to possess a knowledge of the more elementary portions of the calculus and of pure and analytical geometry, including the theory of cross-ratio, involution, projection, reciprocation, and inversion. Without a good knowledge of the subjects named the student's progress will not be rapid, and occasionally, as, for example, in the study of superlinear branches, some familiarity with the theory of the expansion of algebraic functions is almost a necessity. But any student who is in earnest will find in Prof. Hilton's exposition an excellent guide to the subject of which he treats. The first eight chapters discuss what may be roughly described as the leading principles—singular points, foci, determination of the branches at singular points, and Plücker's numbers. At an early stage a careful treatment of curve-tracing is given, fully illustrated by well-selected equations, while numerous examples, with hints for the more difficult cases, are provided for practice in this very necessary part of the student's training.

A compact but careful discussion of the quadratic transformation is given in chap. ix.; to a student new to the subject this discussion should be very illuminating. A good chapter on curves given by a parametric representation is followed by an interesting chapter on "Derived Curves," among which are included evolutes, inverse curves, pedal curves, orthoptic and isoptic loci, cissoids, conchoids, and parallel curves. This chapter is of special interest, as the geometry of the curves considered figures more prominently than in the chapters which discuss the algebraic developments that are necessarily associated with the subject. Later chapters treat chiefly of cubics and quartics, and probably it would be hard to find anywhere a better discussion; the chapters do not always make easy reading, but they are well worth the most careful study. Two excellent chapters on circuits and corresponding ranges and pencils bring the work to a close.

A valuable feature of the book is the very large number of examples provided for practice; there can be no better training for the student than the careful study of these examples. Hints for their solution are given in many cases, but the chief advantage is that a student is really introduced to the methods of research, and put in a position from which he can undertake independent investigation.

The book is provided with a good index, but it might be considered, in view of a later edition, whether a special list might not be made of the more important curves, and a connected summary given of their leading geometrical properties. Such summaries as are to be found in the recent work of Brocard and Lemoyne on "Courbes Géométriques Remarquables" are very instructive.

Aeronautical Treatises.

(1) *Aeronautics in Theory and Experiment.* By W. L. Cowley and Dr. H. Levy. Second edition. Pp. xii + 331 + plates. (London: Edward Arnold, 1920.) 25*s.* net.

(2) *A Treatise on Airscrews.* By W. E. Park. (The Directly-Useful Technical Series.) Pp. xii + 308. (London: Chapman and Hall, Ltd., 1920.) 21*s.* net.

(1) THE second edition of Mr. Cowley and Dr. Levy's book is now issued, and the authors have seized the opportunity to modify some of the material. This has become possible by the release of official reports for publication. The new items are of an advanced nature, and the book now contains two sections, "Mathematical Theory of Fluid Motion" and "Critical Behaviour of Structures," which are unique in the literature of aeronautics. Both sections are written by the authors as pioneers, for Dr. Levy has a first-hand knowledge of the mathematics of fluid motion and is an original worker in the subject, whilst the "Critical Behaviour of Structures" is the result of joint study by the authors of the complex problems of structural theory.

Throughout the book there is much more theory than experiment, and for the latter the data are, as usual, taken mainly from the reports of the Advisory Committee for Aeronautics. The selection of items in reference to points under consideration is good, and the book can be recommended as sound. It is distinctly a student's book, and is not modelled on the needs of the designer like the great bulk of publications on the subject. In range it covers, sometimes in quite an elementary manner, both the aerodynamic and structural problems connected with the aero-

plane, and should make a good preliminary text-book for a degree in aeronautics.

(2) In his preface Mr. Park says that his aim has been to consider problems of airscrew design and construction from the point of view of the designer. In so doing he explains methods developed for the Lang Propeller Co., Ltd. A very considerable degree of success has been attained, and the book is not difficult to follow. The items of calculation are given in great detail, but are connected with the main outlines of airscrew theory so closely that the book may be used by later workers even when they are more up-to-date in their theories.

It is very noticeable that the two latest books dealing with the subject of airscrew design adopt the attitude that the oldest theory agrees better with practice than a new and presumably sounder one. Empiricism has to this extent rather retarded the development of the subject. The theory adopted in the early days of aeronautics ignored the influence of previous passages of the airscrew blade and its companions, and the effect was found in a disagreement between prediction and observation. An examination of the theory by Lanchester, De Bothezat, and others indicated a loss of efficiency and of torque which was great for the stationary airscrew or helicopter, and of less importance at the highest speeds of flight of an aeroplane. The most difficult part of design being the production of an airscrew which allows the engine to develop full power at a given speed, it was found that the introduction of an inflow factor indicated by a modified theory was advantageous. In the later periods of development the magnitude of the inflow factor required has been found to decrease to the point at which it may be ignored. It is highly probable that this is an incorrect view of the phenomena, and that it would be much more sound to attribute the change to an opposing change due to the compressibility of the air. The importance of this latter factor depends on the tip speed of the airscrew, a quantity which has been steadily increasing. No one has yet propounded a working theory which is based on the best established theoretical data.

The greater part of the treatise by Mr. Park is independent of the refinements mentioned above, and gives a good analysis of the possibilities of airscrew design. In commending the book to readers, one may suggest that it will cover the immediate needs both of a designer and of a scientific student of sufficient ability. A thesis of considerable value might be produced as a result of the data of the book and the critical faculties of the student.

Our Bookshelf.

Practical Biological Chemistry. By Prof. G. Bertrand and P. Thomas. Translated from the third edition by Hector A. Colwell. Pp. xxxii+348. (London: G. Bell and Sons, Ltd., 1920.) 10*s*. 6*d*. net.

This work will be found of great value by students and, perhaps more particularly, by teachers of biochemistry. The object of the authors has evidently been to provide a series of laboratory exercises illustrating the properties of the chief substances of biochemical interest, and at the same time affording examples of the methods used in the various branches of biochemical investigation. A large number of tests, interesting preparations and estimations are described in the first part (Statics), whilst in the second part (Dynamics) the subjects of enzymes, micro-biology, and fermentations are treated experimentally.

Although the whole range of biochemistry is dealt with, and the exercises are chosen quite impartially from the chemistry of animal and vegetable life, the treatment is nevertheless very unequal as regards both the selection of methods and the degree of detail given. For example, as all readers would desire, a very full account of the admirable Bertrand method for the estimation of sugars is given, and, similarly, Duclaux's ingenious distillation method for the estimation of volatile acids is fully described. On the other hand, although several pages are devoted to the amino-acids, and Sörensen's formaldehyde titration method is described, there is no mention of van Slyke's method for the estimation of amino-nitrogen, and, indeed, the name of van Slyke does not occur in the index. Again, the conception of hydrogen-ion concentration is mentioned, but no practical use of it is made in the book. It is on account of this arbitrary element in the treatment that we consider the book as likely to be of greater value for teachers than for students; but whoever uses it will find in it many interesting and unusual experiments. described in a clear and suggestive manner, without too great a load of detail. The translator has done his work well, and has added a few notes, including a detailed description of the use of the Maquenne block for the determination of melting points.

A. Harden.

Wireless Telegraphy: With Special Reference to the Quenched-Spark System. By B. Leggett. (The Directly-Useful Technical Series.) Pp. xv+485. (London: Chapman and Hall, Ltd., 1921.) 30*s*. net.

We welcome this volume, which gives full practical details of the "Telefunken" or quenched-spark system of radiotelegraphy. (We use this word, for we think it will shortly receive international sanction.) Practically all the treatises on this subject published in English concern themselves mainly with the Marconi system, and dis-

cuss very briefly, if at all, the quenched-spark system. In 1906 Max Wien showed that it was possible to quench the oscillations in the primary circuit of the sending station after a few oscillations, leaving the bulk of the electromagnetic energy to be expended in, and radiated from, the antenna circuit alone. Hence the efficiency and the amount of energy radiated are practically doubled. The system is the standard one in Germany; and the author thinks that possibly national prejudice has prevented us from judging its merits fairly.

It is far too early yet to standardise in radiotelegraphy. The Marconi Co. has entered into an agreement with the Telefunken Co., and this will probably eliminate much healthy competition. The United States has adopted the Telefunken system for both land and ship stations, and Messrs. Siemens, of Woolwich, have fitted many stations of this type on both British merchant- and war-ships. We agree with the author in thinking that for marine work radiotelephony will be of limited use except in the unlikely event of all maritime nations agreeing to the simultaneous adoption of some form of Esperanto.

An interesting description is given of the station at Nauen, about 25 miles from Berlin, which is the most powerful radio station in the world. Its normal range is 9000 kilometres, and the messages are regularly received in Australia.

The Coco-nut. By Prof. E. B. Copeland. Second edition, revised. Pp. xvi + 225. (London: Macmillan and Co., Ltd., 1921.) 20*s.* net.

THE first edition of this excellent handbook was reviewed in NATURE for February 25, 1915 (p. 695). In the new edition the subject-matter remains substantially the same, and the revision consists chiefly in recording the results of certain scientific work relating to the coco-nut industry carried out in the Philippines during the last six years. Reference is made to the investigations on copra and coco-nut oil by Messrs. Brill, Parker, and Yates in 1917, which dealt mainly with the conditions governing the production of a fine-quality copra of high oil-content. On the cultural side an account is given of the discovery, by Reinking in 1918, that the primary causative organism of bud-rot of the coco-nut palm in the Philippines is *Phytophthora Faberi*, Maub. It would have been useful to mention that a serious bud-rot of coco-nut palms in southern India (Malabar) was described by Shaw and Sundararaman in 1914 as due to *Pythium palmivorum*, Butl. References are also made to interesting work on the growth and behaviour of young and ripening coco-nuts, and to the use of the nuts of young trees as seed. In the foreword the author refers to the impetus given during the war to the export of coco-nut oil from coco-nut-growing countries in place of copra. In his opinion the remarkable advance in this direction made in the Philippines during recent years would have been impossible but for the scientific and educational work on coco-nut cultivation organised by the Philippine Government.

The Early History of Surgery in Great Britain. By Dr. G. Parker. (Medical History Manuals.) Pp. ix + 204. (London: A. and C. Black, Ltd., 1920.) 7*s.* 6*d.* net.

DR. PARKER has written a very delightful account of the rise and development of surgery in our country. He is fortunate in his judgment, his sense of proportion, and his style; he is neither dry nor gossipy. The great figures stand out; nothing could be better than his lightly touched portraits of John of Arderne, William Clowes, Richard Wiseman—all strong-willed, practical, shrewd, kindly, observant men. They were hindered at every turn by their lack of more science; but they were splendid craftsmen and good artists of the living fabric of the body. The stories of their deeds and their adventures, their sympathy, their insight, are fresh and vivid, especially in military surgery. Here and there a note of prophecy is in their work; thus we find Henri de Mondeville (1260–1320) making statements which were fulfilled in Lister's work.

Three great periods come into the book: (1) The twelfth century: the rise of universities and of hospitals; (2) the Renaissance; (3) the eighteenth century: the development of hospital schools and of clinical teaching. The book goes no further; we must read elsewhere of the new learning which came with Pasteur and Lister. It came when surgery was in a bad way. The development of surgery is not constant, and the first half of the nineteenth century was a period of arrest, relapse, almost of degeneracy. Happily, this fine art made a complete recovery. Let us hope that the other fine arts, which now are in an equally bad condition, will follow its example.

Fornander Collection of Hawaiian Antiquities and Folk-lore. By A. Fornander. With translations. Edited and illustrated with notes by T. G. Thrum. Third series. Part iii. (Memoirs of the Bernice Pauahi Bishop Museum. Vol. vi., No. 3.) Pp. iii + 359–546. (Honolulu, H.I., 1920.)

THE publication of the present instalment of the great collection of materials made by Mr. Abraham Fornander, the author of "An Account of the Polynesian Race," will be of great interest to antiquaries and students of folk-lore. Many of the chants now edited in the original dialect, with an English translation and elaborate explanatory notes, the latter mainly based on the notes by Judge L. Andrews, are comparatively modern. Thus the great Wakea Creation chant is the work of the priest-diviner, Kaleikuahulu, who was born in 1725; but doubtless it is based upon ancient tradition. The notes throughout supply complete comments upon the philology, history, and folk-lore which the volume contains. Merely as a collection of materials for linguistic study, the volume, published in admirable style, must be of great value to the philologist.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Aurora of May 13–15.

IN pursuance of the programme outlined in my letter to NATURE of March 31, p. 137, I have been photographing the spectrum of the night sky every night. On the night of May 13–14, and also of May 14–15, a strong auroral spectrum was obtained, showing the aurora line $\lambda 5578$, and also the negative bands of nitrogen, which were much stronger than the aurora line. Ten heads of these bands were shown on the photograph of May 14–15, though only six appear within the same spectral range in Vegard's investigation made on a special expedition to the Arctic.

That these nitrogen bands should be actually stronger than the aurora line is very remarkable. On ordinary nights it is generally possible to photograph the aurora line, while the nitrogen bands have never been photographed in the course of about 100 nights except on these two consecutive occasions.

It is of interest to note that the aurora apparently ceased before the magnetic storm was over, according to the data given by Dr. Chree in NATURE of May 19, p. 359. On the night of May 15–16 the aurora line was barely, if at all, visible on the plate, and below its average intensity on ordinary nights. Nothing could be seen of the nitrogen bands.

RAYLEIGH.

The Gravitational Field of an Electron.

IN the Proceedings of the Royal Society for February last (vol. xcix., A, p. 123) is an interesting paper by Dr. G. B. Jeffery, in which he applies an extension of Einstein's theory to ascertain something about the state of the æther close to an electron—though perhaps he might not express it in that way. He obtains independently, and then discusses, a result recently published by Nordström, namely, an extension of the now well-known γ of Schwarzschild's equation,

$$ds^2=\gamma^{-1}dr^2+\text{etc.}-\gamma c^2dt^2,$$

by adding to it a mixed gravitational and electrical term, so that it becomes

$$\gamma=1-\frac{2Gm}{rc^2}+\frac{Ge^2}{Kr^2c^4};$$

wherein, while the old second term involves the gravitational potential, the new third term involves the square of the electrostatic potential.

I have introduced the dielectric constant of the æther into the denominator so as to keep dimensions right, and if we now choose to make use of the familiar "J. J. T." (1881) expression for the inertia of an electric charge, $m=2\mu e^2/3a$—which is reasonable, inasmuch as the gravitation constant is dominant over both the second and third terms—we may write the above value of γ thus:

$$\gamma=1-\frac{2Gm}{rc^2}\left(1-\frac{3}{4}\frac{a}{r}\right).$$

This expression attains a minimum value when $r=\frac{3}{2}a$; and it is unity both at infinity and at $r=\frac{3}{4}a$. This last probably means that the electric and mass terms just balance at the surface of an electron (for we may probably ignore the $\frac{3}{4}$ factor as unlikely to be accurate so close to a charge), or else it means that the gravitational effect at an electron-boundary is reduced to one-quarter of its normal value. The formula does not apply in the interior of an electron, if an electron has any interior; though if it is a geometrical point, as Dr. Jeffery evidently thinks possible, then γ may rise to a very high value within what is commonly thought of as the boundary.

It is not to be thought that the new term is merely the natural consequence of electromagnetic mass, for it is opposed in sign; the electrical and the mass effects tend to neutralise each other; but nowhere do they succeed except at or near the boundary of an electron. For all distances large compared with the size of an electron γ has its customary Einstein value, so the third term has no astronomical significance whatever.

But a study of what happens to radiation when it impinges on, or penetrates between, the ultimate elements of matter—in fact, a study of the whole behaviour of a stream of radiation at its two ends, the source and the sink—is obviously of great importance. An immense amount of work has been done on the emission end of radiation, but less on the absorption end. By the two together we may ultimately hope to get some information as to the structure of an electron. It may be pardonable to mention some small papers of my own in this connection, in the *Philosophical Magazine* for April and probably for June and July this year, though the full working out is not attempted.

It must be emphasised that the e^2, above, means the square of the unbalanced charge only—it is $(\Sigma e)^2$ not $\Sigma(e^2)$—and that all neutralised charges are provided for by the second term. The conclusion that unbalanced electric potential and neutralised or mass potential oppose each other in their warping effect on the æther appears rather suggestive. I confess I should have expected a third term which did not involve the gravitation constant; and perhaps there may be a reconsideration on this point, for the present manner of obtaining the expression is far from easy—in fact, is abstruse.

OLIVER LODGE.

The Magnetic Storm of May 13–17.

THE magnetic storm which began soon after 1 p.m. on May 13 presented several unusual features beyond that of almost unprecedented magnitude. As recorded on the Eskdalemuir magnetographs, it showed a "sudden commencement" at 13h. $1\frac{1}{2}$m. G.M.T. on May 13. The phenomenon known by this name usually takes the form of a sharp change in value of the horizontal components of terrestrial force, frequently including as its first part a temporary drop in value lasting for about a minute, but always exhibiting a rise in value immediately thereafter. In the vertical component the change, when appreciable, is very much slower and is in the direction of the zenith. In the case of the storm now described the change in the north component was too quick for the photographic paper to receive a visible impression of the light spot. On the west component a drop in value is shown at first, amounting to 29γ (0·00029 C.G.S.) and extending over two minutes. There then followed a rise of 94γ, occupying $2\frac{1}{2}$ minutes. On the vertical component the "sudden commencement" assumed an unusual form. There is quite clear evidence of a preliminary increase in value of the vertically downward directed force amounting to 8γ, followed immediately by a reverse change of 31γ, the latter being much more rapid than is generally the case. These preliminary phases having passed, the main features of the disturbance were quickly developed. This is quite in accord with the results of

previous experience, which shows that, as a rule, when a "sudden commencement" occurs not far from noon of local time the principal maxima and minima of the storm occur within the next twelve or fifteen hours, but that if the "sudden commencement" occurs late in the day the full development of the disturbance is postponed until the *post-meridiem* hours of the following day.

The changes in the horizontal components of force throughout the disturbance were on a very large scale, and took place with a rapidity so great that the photographic traces are in some parts too faint to read. But the most unusual feature of the storm was the remarkable series of changes in the value of the vertical component of force. In most magnetic storms the general course of events comprises (1) a gradual increase in V to a maximum (in some cases two successive maxima) reached about 18h. local time, (2) a gradual fall until midnight, (3) a rapid fall to a minimum which is reached about 1h., (4) a gradual recovery to nearly the undisturbed value, which recovery is completed by about 8h., and is sometimes accompanied by (5) a series of short-period pulsations. The whole sequence is frequently repeated on a modified scale later on in the second day. In the storms now described this course of events was followed so far as the first twenty-four hours are concerned. The first maximum on May 13 was reached at 20h. 37m., and was 152γ above the undisturbed value at the time of the "sudden commencement." One or two falls in value succeeded until 21h. 24m., when a rapid fall of more than 350γ in six minutes carried the light spot off the paper. The principal minimum which then occurred took place at an unusually early hour (see "British Meteorological and Magnetic Yearbook," 1915, part iv., p. 89, and plate vi.). According to the theory which would account for magnetic storm phenomena by assigning them to the earth's rotation in a beam of particles emanating from the sun, this sudden drop in the value of V might be supposed to take place at or soon after midnight of local time, but not so early as 9 p.m. The rate of change in V during the descent to the minimum referred to was large, but by no means the largest recorded at Eskdalemuir. For example, the storm of March 23, 1920, showed a case of V changing at the rate of 169γ per minute. The gradual recovery which followed the minimum was accompanied, particularly between 6h. and 8h., by pulsations of about four minutes' period and of amplitude averaging about 4γ. It is, perhaps, unsafe to generalise, but there is some evidence to show that such pulsations in vertical force do not occur in a magnetic storm unless the total range of disturbance in V exceeds a certain amount.

The second twenty-four hours of the storm showed even more remarkable developments than the first. After several maxima and minima had been passed the value of V began to fall about 23h. on May 14, and the light spot went off the paper at midnight. Between 1h. and 6h. on May 15 at least a dozen extensive and rapid changes in V took place, swinging the light spot alternately beyond the upper and below the lower edge of the paper. The most clearly marked of these occurred between 2h. 40m. and 2h. 44m. on May 15, and involved a change during that interval at the rate of 138γ per minute. Repeated oscillations of this character and magnitude have not hitherto been recorded at Eskdalemuir. The course of the disturbance during May 16 was remarkable in that the fall in the value of V during the early hours of the morning continued until nearly 7h.

The storm had practically died down by noon on May 17, but soon after 22h. on that day another "sudden commencement" was recorded, and the sheet which will be taken off the recording drums to-morrow morning will probably show a recurrence of disturbance.

A. CRICHTON MITCHELL.

Eskdalemuir Observatory, May 18.

Ocean Tides.

THE article in NATURE of March 10, p. 33, on oceanographic problems by "J. J." prompts one interested in tides to direct attention to the services which a new *Challenger* expedition might render to the general theory of ocean tides at relatively little cost either in time or in money.

There are numerous localities for which tidal information is either inadequate or wholly lacking. Sir George Darwin directed attention to some of these places by publishing in the *Geographical Journal* of November, 1909, a memorandum prepared by the late Dr. R. A. Harris, of the U.S. Coast and Geodetic Survey. The "dozen or so landing parties placed here and there over the world" suggested by "J. J." could undoubtedly use to advantage as their bases of operations some of these places for which tidal observations are needed. These suggested landing parties could therefore, in connection with their other observations, secure tidal data of great value.

It may not, perhaps, be amiss here to point out that such tidal observations would serve two important purposes. In the first place, they would increase our geographical knowledge of the regional distribution and local characteristics of the tides; and in the second, they would furnish further data of an accurate character to test the merits of the various tidal theories that attempt to interpret mathematically the terrestrial phenomena of the tides. Thus some of the places for which tidal information is desired are of critical importance to the so-called "stationary wave" theory of tides, which appears steadily to be gaining in favour.

The use of automatic or self-recording tide gauges would, of course, be most desirable. In this connection it is to be noted that such tide gauges may now be had in small and inexpensive types that require no elaborate installation and may be expeditiously set up. It cannot, however, be too strongly emphasised that valuable additions to our knowledge of the tides at out-of-the-way or infrequently visited places may be secured by recording hourly the height of the tide as registered on a naked tide-staff graduated to feet and tenths. The longer the series of observations, the better; but even a day or two will furnish considerable information.

The value of the tidal observations would be greatly enhanced if bench-marks of a permanent character were established and the relation of the zero of the tide-staff to these bench-marks determined. This would make possible correlation with any future tidal observations at the same places, and might even permit a quantitative determination of the local rate of elevation or subsidence of the land relative to the sea.

A fertile and almost virgin field is offered to the investigators of a new *Challenger* expedition in the study of the tides of the open sea, the importance of which is obvious. Several forms of automatic tide gauges adapted for offshore tidal observations appear to have given satisfactory service. Recently an offshore hydrographic party secured an excellent series of tidal observations by means of an improvised tide gauge consisting of a graduated tide-staff secured to a float and confined in a float-tube made up of sections of 2-in. pipe, the lowest section of which was cast into a block of cement. It also appears that satis-

factory results may be obtained by means of a sounding wire attached to a heavy block of concrete or box of stones (see *Science*, vol. xlii., 1904, p. 704).

Those members of the new *Challenger* expedition whom fortune may choose to be responsible for the tidal observations have it in their hands to make all tidal workers using their data everlastingly grateful. This gratitude they may secure by insisting that the tidal observations should be made in Greenwich mean civil time, reckoning the hours from 0 to 23. Apart from the many advantages for purposes of computation resulting from such procedure and the ease with which time comparisons of the tide at different places may be made, there is one outstanding advantage—it will remove all uncertainty as to the kind of time used. Many otherwise excellent tidal observations are of little use because there is no certainty as to the kind of time employed, whether mean local civil, mean local astronomical, local apparent or standard time for some unknown meridian. The use of Greenwich mean civil time should prove further desirable in view of the change to this kind of time soon to be made in the Nautical Almanac published by the British Admiralty.

H. A. MARMER.

U.S. Coast and Geodetic Survey, Washington, D.C., April 15.

The Physical Status of "Space."

To answer all Mr. Bonacina's points (NATURE, May 5, p. 300) is not possible in a single letter. I agree with him that no rigid boundary can be drawn between the provinces of the older physics and metaphysics. Concepts are freely introduced into both which are not known to experience, and are never used either in describing past experience or in inferring future experience. Some hypotheses are necessary in any science, but hypotheses that are never used are neither necessary nor useful. The elastic solid æther forms an excellent example of these. It is assumed that electric and magnetic forces satisfy certain differential equations, and this is the only assumption required for the theory of the propagation of electromagnetic waves. The æther theory, however, introduces the additional hypothesis that one of these forces is a displacement in an elastic solid the properties of which differ from those of any ordinary solid. This assumption is never used, has no basis in experience, and cannot be tested experimentally. Accordingly I say it should not be made, for the introduction of additional hypotheses decreases the probability of the theory. The other assumption, which is valuable and leads to much new knowledge, makes no mention of an æther. It appears to be the case that all so-called explanations of physical laws by means of the æther are really based on some mathematical assumption that makes no reference to an æther at all.

I cannot see Mr. Bonacina's difficulty about "empty space." I have advanced no theory involving any such entity, and think that space is as useless a concept in physics as æther. To construct a space with suitable properties may be an aim of physics, but it is certainly not the starting point. The existence of entities incapable of being objects of experience is a thorny problem even to metaphysicians, and I think that physicists would do well to postpone its consideration so far as possible until they have some idea of the basis in their knowledge of the propositions to which they attach high probabilities.

Dr. Campbell's point (May 5, p. 301) is dealt with in the article (NATURE, February 17) of which I was part author. Geometry is *not* the measurement of the earth, and never was; it was pointed out in the article that that excellent idea in nomenclature was never carried out. Euclid's geometry was, from the nature of its constructions and postulates, quite inapplicable to earth measurement. If anyone doubts this, let him consider the definitions and axioms as they stand and see how many of them are verifiable in even a few cases on a scale such as occurs in surveying. Further, Euclid's treatment assumes that the postulates are true in all cases. To suggest that this can be known by experiment is ridiculous. It is at best an inference to which a high probability can be attached. I know of nobody but Einstein and his followers who has used the word "geometry" in any other than the mathematical sense. The measurement of the earth is always known as "geodesy," and has been for more than a century; and measurement in general is "mensuration," the most important and least discussed of all sciences. Constancy in terminology requires that these meanings should be retained. Dr. Campbell would scarcely claim that measurement in general should be called "geometry" in *his* sense.

HAROLD JEFFREYS.

The Reparation Act and Scientific Research.

PROF. GARDINER (NATURE, May 19, p. 359) is one of many British men of science who are helping to pay the German war indemnity. One does not obtain goods from Germany unless one is compelled; it is difficult to see how standard German books and new publications can be procured from home industries, and they are necessary to research. In other cases the goods might be expected to be made by British firms. For many months I have been trying to obtain Wollaston wire of a certain diameter from a well-known British firm. At first I was informed that it could not possibly be made. I had bought it before in Germany, so they tried to make it. Several samples were unsatisfactory, and finally I was told that the British firm did not wish to make any further attempts. I then ordered some of the German wire, which I was required to pay for in advance, for the reason stated by Prof. Gardiner. This was reasonable, as the price charged by the German firm, *plus* indemnity which I pay, is less than I have been paying for unsatisfactory wire in England. The wire was on the way for several weeks. Meanwhile work was delayed. The Customs officials know nothing of the reduction of the tax from 100 per cent. to 26 per cent., announced by Mr. Chamberlain. Another order for new books, given in February, was dispatched from Bonn on March 4, and arrived in London on April 12 and April 16. Notice from the Customs was received a month later. After two days spent at the Customs filling up forms, and five letters requesting delivery, I still await the latter.

The condition of the British man of science who elects to do research will soon become impossible. Perhaps that is really the idea behind all this. The extension of the "key industry" idea will finish us altogether.

J. R. PARTINGTON.

East London College, University of London, May 20.

The Resonance Theory of Hearing.

I SHOULD like, in the first place, to take this opportunity of thanking Dr. Perrett for his reply in NATURE of May 5 (p. 301), but I feel difficulty in accepting the explanation he there advances on the displacement hypothesis, because it does not seem to me to fit in

with the following observations. When a short interruption is made in a musical note it is not a beat (*i.e.* a short silence) that is heard, but, on the contrary, a short noise which appears to add itself to the uninterrupted note. The way this short interruption is produced and an explanation of the noise that results according to the resonance theory of hearing will be found in the *British Journal of Psychology* (vol. xi., 1921, p. 277).

If, then, in order to change the phase of a note by π, the usual interval between successive impulses is altered from τ to $\tau \times \frac{3}{2}$, the beat (*i.e.* the silent interval) which the observer hears cannot be due to the mere interruption in the sequence of the waves, because experiment shows that such an interruption would be heard as a short noise. But, further, even if Dr. Perrett's explanation could be accepted for the case where the interval is increased from τ to $\tau \times \frac{3}{2}$, it clearly could not, I think, apply to the case where, in order to introduce a change of phase of π, τ is reduced to $\tau/2$; for on Dr. Perrett's reasoning no beat should be evident in this case, whereas experiment shows it to be present. H. HARTRIDGE.

King's College, Cambridge.

Hæmoglobin in Mollusca.

SIR RAY LANKESTER will find some interesting experiments on the usefulness of hæmoglobin to Planorbis and Chironomus larvæ in a paper by Leitch in the *Journal of Physiology* (vol. l., 1916, p. 370), in which the author indicates that its respiratory value comes into play only when the oxygen pressure is quite low. This does not, of course, solve the problem as to why there should be various closely allied mollusca (Limnæa) living side by side with Planorbis, and with apparently equal success, which have no hæmoglobin beyond a trace in the muscles of their lingual apparatus. The possession of a considerable quantity of hæmoglobin seems to be a generic character, since it is present in all the species of Planorbis, which differ a good deal among themselves in their habits and in their capacity to live in clean and dirty water, and absent in all sorts of Limnæa. Sir Ray Lankester seems to have forgotten what he taught me in his elementary class twenty-six years ago: that hæmoglobin has come to have secondary (decorative) uses in man; but he will perhaps be as loath to admit an æsthetic sense in snails and their companions as he has been to accept the selective intelligence of Earland's foraminifera in building their tests. But the albino form of *Planorbis corneus* found by Mr. W. T. Webster near Barnet, in which the colour of the hæmoglobin is not obscured by black pigment, is certainly a gorgeous spectacle. A. E. BOYCOTT.

17 Loom Lane, Radlett, May 14.

Physiological Reactions in the Protozoa.

IT would be deplorable if the letter by Mr. Ludford, and with the address of a zoological laboratory (NATURE, May 12, p. 332), should be thought by anyone to represent the attitude of zoologists in general or of protozoologists in particular towards physiological problems. It would be hard to find a more individualistic reaction than the "grouping" of Protozoa in direct response to a particular chemical or physical stimulus. Typical experiments are described in every physiological or protozoological text-book, and it requires some imagination to see in such behaviour "the dawn of a gregarious instinct."

It is difficult to understand how any student of zoology or biology could have written the sentence beginning "On the part of Protozoa, protection against toxins in the water is a necessary *precaution that has to be taken* to safeguard the individual" (italics mine). Do the Protozoa really practise sanitary science, and are they no longer subject to natural selection? J. S. DUNKERLY.

Zoology Department, The University, Glasgow.

Picture-hanging Wire.

IN reference to Mr. Marston's letter upon the above subject (NATURE, May 19, p. 362), I have for many years past used and advocated the use of plain copper wire in preference to any other means of suspension. The only matter that calls for careful attention is avoidance of "kinks." With heavy pictures my practice is to have two entirely independent suspensions —screw-eyes, wire, and wall nail or hook—the duplicate being entirely screened by the picture, and either actually or so nearly sharing the weight that should the other suspension fail it could take the whole load at once without jar.

If I use a (nailed-on) wall-hook I put a stout nail immediately beneath to provide against failure of the brass hook, and I have found it a good plan when using a brass-headed nail to drive in a wire nail at a steep angle beneath it so that the head of the wire nail lodges beneath the brass head. The wire nail acts excellently as a strut. A. J. STUBBS.

Anode Rays of Beryllium.

THE method of anode-ray analysis which was used to determine the isotopes of lithium (NATURE, February 24, p. 827) has recently been applied to the case of beryllium. A well-marked parabola was found corresponding to a single charge and an atomic weight $9{\cdot}0 \pm 0{\cdot}1$ (Na=23). No second line was observed which could with certainty be attributed to beryllium, but the parabola at 9·0 was not so strong as that at 7·0 for lithium, and it is doubtful if one of a tenth the intensity could be observed. On one plate a scarcely perceptible indication of a line was found in the neighbourhood of 10, but as more recent photographs, in which the line at 9 was stronger, did not show it, it seems likely that it was not due to beryllium. No indication was found which would suggest that the atom of beryllium can lose two electrons under the conditions of these experiments. G. P. THOMSON.

Cavendish Laboratory, Cambridge, May 23.

The Colours of Primroses.

MAY not Dr. Heslop Harrison's experiences of primulas (NATURE, May 19, p. 359) be due to the influence of cold and somewhat resemble what is seen in our so-called copper-beech in the spring and early summer? Few seem to be aware that during the summer its characteristic colour entirely disappears and it then has the ordinary green foliage. Other plants, too, *e.g.* some varieties of roses, show the same sensitiveness. G. ABBOTT.

May 24.

The Japanese Artificially Induced Pearl.

By Dr. H. Lyster Jameson.

On May 4 a London evening paper announced that quantities of artificially produced Japanese pearls, of perfectly spherical shape, but containing in their centres beads of mother-of-pearl, had found their way into the London market and had deceived experienced pearl merchants in Hatton Garden, who had bought and resold them as naturally produced gems. Since that date many inaccurate, misleading, and contradictory announcements have appeared in the daily papers, leaving the public, both lay and scientific, in some confusion. The following statement of the position, so far as it can be judged from the scientific point of view, may therefore be useful.

Fig. 1.—Section through the centre of a natural pearl, × 6½. (Ordinary light.) Preparation and photo by Mr. A. Brammall.

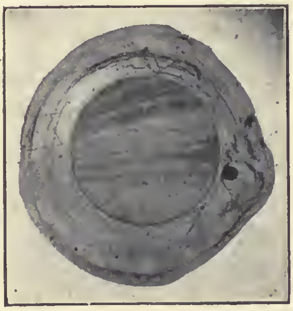

Fig. 2.—Section through the centre of a Mikimoto pearl, × 6½. (Ordinary light.) Mr. A. Brammall.

For some years Mr. K. Mikimoto, the pioneer in the application of scientific knowledge to the pearl oyster on a commercial scale, has been producing in Japan, and selling under the name of "Mikimoto pearls," pearls of this description. There was no secret about this. Mr. Mikimoto not only sold them as artificially produced pearls, but also published in one of his catalogues (No. 33) a short description and diagram explaining his process.

Ever since 1898 Mr. Mikimoto (who began his work in collaboration with the late Prof. K. Mitsukuri in 1890) has been marketing half-pearls or "blisters," pearly excrescences formed by inserting a mother-of-pearl bead between the body of the oyster and the shell, and allowing the oyster to coat it over with nacre. This was, of course, merely a development of the very old operation by which the Chinese produce, in fresh-water mussels, the well-known mother-of-pearl images of Buddha, and of Linnæus's classical experiments in the eighteenth century. These products were known as "culture pearls," and have long been familiar in this country, set in brooches, tie-pins, rings, etc. Their value, compared with real pearls of corresponding sizes, was, of course, quite small.

For many years Mr. Mikimoto experimented with a view to the production of a complete pearl, not attached to the shell, by a modification of this process, and obtained his first successful results about 1912, as announced by me at the Dundee meeting of the British Association in that year. From information supplied to me by Mr. K. Ikeda, one of Mr. Mikimoto's staff, in a letter from Tokyo dated May 30, 1914, it appears that the first considerable crop of these "round cultivated pearls" was harvested in the autumn of 1913. Their production is now an important part of the original Japanese industry.

Apart from the purely financial question as to the degree to which the advent of artificially induced pearls is likely to affect the price of natural pearls, two questions seem to have been agitating the public: Are these products "pearls"? and Can a test be devised by which, without destroying them, they can be distinguished from pearls of natural origin?

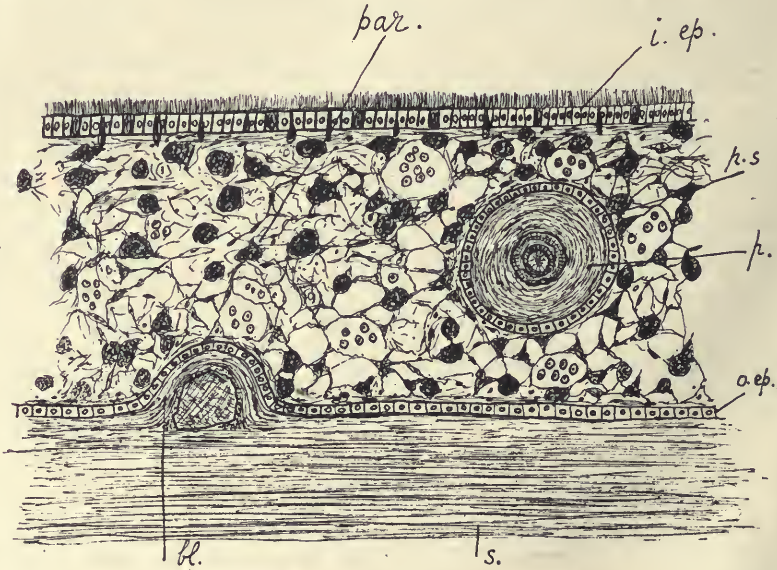

Fig. 3.—Diagram illustrating the difference between a pearl (*p.*) and a blister (*bl.*). *s.*, substance of shell; *o.ep.*, outer shell-secreting epidermis; *p.s.* pearl-sac, formed of shell-secreting epidermis; *i.ep.*, inner ciliated epidermis of mantle cavity; *par.*, parenchymatous connective tissue of mantle.

Of course, when a slice is cut across a natural pearl and a Mikimoto pearl the distinction is obvious. A natural pearl, except in those (in my experience exceptional) cases where a nucleus of foreign origin and of sufficient size to be identified

(such as a grain of sand) is present, consists throughout of concentrically deposited layers, which differ in degree of transparency or opacity in different specimens (Fig. 1). The Mikimoto pearl, in its outer layers, has the same structure as the natural pearl, but has an artificially manufactured bead of mother-of-pearl, composed of flat parallel laminæ of nacre, in its centre (Fig. 2). (These preparations and photos were made under the supervision of Mr. Brammall, to whose investigations reference is made below.)

The method by which Mr. Mikimoto produces these pearls has been patented by him in Japan and other countries, and an application for a British patent has already been filed, and is open for inspection at the Patent Office. The information here given was obtained from this specification, from a short description and figure published in one of Mr. Mikimoto's catalogues, and from facts supplied by Mr. Toranosuke Kato, his London representative. The process involves the most delicate and skilful manipulation, and it could be carried out, presumably, only by carefully selected and trained workers. The shell is removed from one pearl oyster, and a bead of nacre or other suitable nucleus is laid on the outer shell-secreting epidermis of the mantle. This epidermis, which is composed of a single layer of cells of microscopic size, is then dissected off the oyster, and made to envelop the nucleus as a sac, the neck of which is ligatured. This sac is then transplanted into a second oyster and embedded in its sub-epidermal tissues, the ligature is removed, certain astringents or other reagents are applied to the wound, and the second oyster, with its grafted pearl sac containing the mother-of pearl bead, is returned to the sea, where it has to remain for several years before a coating of pearl of sufficient thickness is secreted around the introduced bead. (In his letter of May 30, 1914, Mr. Ikeda stated that it took seven years.)

Now Mr. Mikimoto's success is based on the fact, which follows from my work in 1902,[1] and was further demonstrated by Alverdes's remarkable experiments ten years later,[2] that *it is not the presence of an irritating intrusive body that determines the formation of a pearl, but the presence in the sub-epidermal tissues of the oyster of a closed sac of the shell-secreting epidermis,* the secreting surface of which is not continuous with the secreting surface of the epidermis which lays down the shell; and that unless this epidermal sac is introduced by transplantation (as in Alverdes's and Mikimoto's methods), or is induced by the specific stimulation of a particular kind of parasite (as in the pearls in Mytilus caused by the trematode Gymnophallus), or arises by some still unknown cause or causes (as in the Ceylon pearl oyster), no irritating body introduced into the shell or tissues can be expected to become the nucleus of a pearl. In my 1912 paper[3] I showed that the vast majority of pearls from the true pearl and mother-of-pearl oysters have no recognisable nuclei of foreign origin, the bodies so often taken for such, like the dark portion of the pearl shown in Fig. 1, and the centre of the pearl diagrammatically shown in Fig. 3, being composed of a kind of shell substance of pathological origin, identical with that with which the oyster repairs an injury to its shell.[4] On the other hand, some of the natural pearls I have examined contained foreign bodies which (apart from the special case of the trematode which causes pearl sacs to form in Mytilus) ranged from diatoms and fragments of radiolarian shells and sponge spicules to quartz grains measuring, in one case, as much as 0·8 mm. in diameter. I propose to outline a theory attempting to account for the presence of these bodies in a later paper.

From the biological aspect there are two classes of pearly bodies. For the first of these, to distinguish them from true pearls, I adopted the name "blisters," familiar to pearl fishers, in 1902. Blisters (Fig. 3, *bl.*) are excrescences on the interior of the shell formed to close holes made by shell-boring animals, or to coat over intrusive objects such as grains of sand, small crabs, Fierasfer, etc., and, in the case of the Buddha "pearls," Linnæus's "pearls," and the "half pearls" originally produced by Mr. Mikimoto, metal images or beads. Over such a blister the epidermis forms a little pocket, directly continuous with the shell-secreting epithelium. A pearl, on the other hand (Fig. 3, *p.*), is formed in a closed sac of shell-secreting epidermis, which is embedded in the tissues of the oyster, and the nacre-secreting surface of which is not continuous with that of the epidermis that lays down the shell itself. A blister is a more or less hemispherical body passing over on all sides into the shell substance; a pearl is a concentrically deposited body, the substance of which is nowhere continuous with that of the shell. A pearl may, in the course of time, be ejected into the space between mantle and shell, and become more or less buried in the shell, forming the core of a blister; but in that case it can be dissected out from the shell layers deposited over it.

The trade distinguishes different kinds of pearls according to shape and size (fine pearls, baroque pearls, seed pearls, etc.), just as biologists distinguish certain classes according to where they arise (parenchyma or mantle pearls, muscle pearls), or to the kind of shell material of

[3] Jameson, Proceedings of the Zoological Society, 1912, pp. 260–358.

[4] It is astonishing how the "foreign nucleus" theory of pearl formation sticks, as witness the utterances of scientific men of standing which have been called forth by the recent announcement.

which they are composed (nacreous pearls, columnar pearls, hypostracum pearls, periostracum pearls, hinge pearls). All these classes, some valuable, some worthless, are, from the biological point of view, *pearls*. Biologically speaking, the Mikimoto pearl satisfies all the conditions which go to make up a pearl as defined above. It differs from a natural pearl only in that it contains a foreign nucleus larger than any foreign nucleus which I have so far encountered in a natural pearl, and in that this nucleus is a bead of mother-of-pearl such as does not occur in Nature. Both these points could easily be remedied. A smaller nucleus could be introduced; or the nucleus might be removed after grafting the sac in the oyster; or a small natural pearl of inferior quality, or a concentrically crystallised bead of carbonate of lime, could be used as a nucleus. A trade in the worthless pearls of Mytilus might even be revived for this purpose; according to Garner they were once exported from this country to China for the manufacture of "medicine." The somewhat greater transparency, on the average, of Mikimoto pearls, when compared with natural pearls, could be remedied by either of these processes.

With regard to the question of distinguishing the Mikimoto pearl without cutting it, much vague talk as to scientific investigations has appeared in the daily Press. Some of these investigations remind me of the little boy who, having learned that trains were propelled by steam, lighted a fire in his go-cart, put a kettle on it, and expected it to run by itself. Undoubtedly experienced pearl merchants, and, indeed, any zoologist who is familiar with the shells of the different species and geographical races of pearl and mother-of-pearl oysters, can usually distinguish pearls from the Japanese pearl oyster (*Margaritifera Martensii*) from the pearls of other species, just as they can distinguish Ceylon, Australian, Central American, etc., pearls from each other by slight differences in colour and lustre; but this test only reveals that the pearls come from the Japanese pearl oyster, and cannot be used to distinguish naturally and artificially produced Japanese pearls from each other; and it would be useless for distinguishing pearls produced by the Japanese process in other species of pearl oysters from pearls naturally produced by the same species.

This natural difference is greatly intensified when the pearls are examined in ultra-violet light, for which purpose an apparatus has been designed and is already on the market. I hope shortly to be able to examine some naturally produced Japanese pearls with this apparatus. I anticipate that they will agree with the artificially produced Japanese pearls, and not with natural pearls from other localities, as this test, like the rule-of-thumb test based on the general colour and lustre, appears to depend on the minute differences in the structure of the nacre in different species and races of pearl oysters.

Immediately on the first announcement of the presence of these pearls in the market being made, I suggested to a Press representative who called upon me that polarised light was the most hopeful line along which to seek a test that would reveal the presence of the artificial nucleus, and this suggestion was published in one of the daily papers on May 5. Immediately afterwards I got into communication with Mr. A. Brammall, of the Imperial College of Science and Technology, South Kensington, who has since been engaged upon experiments which aim at determining whether polarised light can be applied to whole pearls in such a way as to furnish a test.

The behaviour of polarised light when passed through *sections* of the natural and the Mikimoto pearl respectively was a foregone conclusion from our knowledge of the structure of their centres. When examined with polarised light between crossed Nicols, the section of a natural pearl, of course, shows throughout the cross of extinction characteristic of concentrically crystallised bodies (except in those parts which are too opaque to transmit light). A section of a Mikimoto pearl, on the other hand, shows the four arms of the cross in the outer part, which is concentrically laid down; but the mother-of-pearl bead appears alternately dark and light as the slide is rotated, according as the part of the exterior to which its laminæ are parallel is in a dark or a light sector. Mr. Brammall is not yet in a position to make a definite statement as to the practicability or otherwise of applying some modification of this process to the whole pearl. He will, of course, publish his results as soon as they are completed.

However, whether or not the pearls, produced by the Mikimoto process, which are now on the market, can be distinguished from naturally produced pearls, without destroying them, by virtue of their containing a large bead of mother-of-pearl, which behaves differently towards polarised light or towards some other variety of light, Mr. Mikimoto can easily remedy this in future by a modification of his process, such, for example, as one of those suggested above. That being so, and having in view the fact that, in the appropriate localities, "Oriental," Australian, Central American, and other varieties of pearls could be produced by the same process, it is probable that, as time goes on, more and more of the pearls coming into the market will have been produced, not by the old-fashioned methods of fishing for the "wild" pearl oyster, some of which methods have existed almost unchanged from time immemorial, but by such applications of scientific knowledge to cultivated pearl oysters as that in which Japan has given so conspicuous a lead.

The Recent Magnetic and Electrical Disturbances.

By DR. C. CHREE, F.R.S.

THE recent magnetic and electrical disturbances have been remarkable for both their intensity and their persistence. Magnetic disturbance went on without any considerable interlude from shortly after 13h. (G.M.T.) on May 13 to 4h. or 5h. of May 17. This was followed by notable disturbances on May 19 and following days. There was, however, a distinctly quieter interval between May 17 and 19. Thus the storm was really less persistent than one presenting very similar features which began late on November 11, 1882, and continued practically without a break for nine or ten days.

As regards aurora, much depends on the season of the year, the age of the moon, and the amount of cloud. In the North of Scotland, the principal auroral region of the United Kingdom, twilight lasts so long in May that the chance of aurora being visible is but small. During the recent magnetic storm, aurora, if not generally brilliant, has been seen in a number of places. At Cambridge, aurora was seen to rise as high as the zenith on the night of May 13, and in the early morning of May 15 aurora was observed with a bright red colour. Aurora was also reported from London and other stations in southern England, where it is a rare event even at the equinoxes. Large earth-currents have been observed in the Post Office telegraph system at stations in England, Scotland, and Ireland.

The magnetic disturbances recorded at all the magnetic observatories have been of a quite exceptional nature. They reached a climax on the night of May 14–15. Almost all large magnetic storms show shorter-period oscillations superposed on changes having a more or less persistent direction for a considerable time. But the extent to which short-period oscillations prevail varies much in different storms. Also in many cases, while the disturbance of the horizontal components is considerable, the vertical force (V) shows little disturbance, and rapid oscillations of any size in that element are very rare. During the recent disturbances the persistence and size of the short-period oscillations were remarkable, and during the night of May 14–15 this characteristic was shared by V to a quite exceptional extent. The magnetic storm of November, 1882, already referred to, also showed this phenomenon, so that, though rare, it is not absolutely unique. The year 1882, it may be noted, like 1921, was not characterised as a whole by abnormal sun-spot development.

The storm has received unusual attention in the newspapers. The writer of a leading article on the subject in the *Times* of May 19 has referred to the difficulty of providing the large store of energy required, seeing no alternative to the acceptance of the estimate made many years ago by Lord Kelvin other than the giving up of the principle of the conservation of energy. As the storm considered by Lord Kelvin was very trifling compared with the recent one, the conservation of energy may appear in a hopeless case. It may thus comfort the general reader to know that a recent estimate by Prof. S. Chapman gives a result which is nearly one million-million-million times less than Lord Kelvin's. When Lord Kelvin made his estimate his position resembled that of an eighteenth-century engineer consulted as to the possibility of warming London by burning coal in the Midlands. The better the engineer of that epoch, the deeper the pessimism to be expected. But the modern engineer, familiar with high-tension electrical transmission, whatever he might think of the scheme as a financial proposition, would not consider its realisation fatal to the conservation of energy.

If, as some modern theorists have suggested, atmospheric electric potential at the earth's surface should show some response to magnetic disturbance. the morning of May 15 was the time when the phenomenon should have declared itself. Unfortunately, some rain fell that morning in London, and a decisive answer to the question must be sought elsewhere.

The Recent Large Sun-spot Group.

By H. W. NEWTON, The Royal Observatory, Greenwich.

THE large sun-spot which appeared on May 8 is remarkable in several respects. The sun-spot cycle reached its maximum in 1917, and the occurrence of a large group some four years later, though by no means unique, is a matter of interest apart from its association with an intense magnetic storm. The spot group has been photographed daily at Greenwich, and reproductions of some of the photographs are given. Fig. 1 shows the disc of the sun on May 13, on which day the magnetic storm commenced. Fig. 2 illustrates the group in detail and the considerable changes taking place in a few days. The most interesting features of the group are (*a*) its position exactly on the sun's equator; (*b*) its abnormal development; (*c*) its position at the time of the magnetic storm.

(*a*) It is a well-established fact that the change in latitude of the sun-spots is cyclical in the same eleven-year period as their frequency. Soon after the commencement of a new cycle, spots appear mainly about latitude 25° north and south of

the sun's equator. As the cycle progresses they become most numerous in successively lower latitudes, while at the present phase of the cycle they are found most frequently in latitude 10°. Very large groups on the equator are rare, however, and the present one is the largest which has appeared in this position during the last half-century. Looking at Fig. 1, it is necessary to bear in mind that at the middle of May the north end of the sun's axis of rotation is about 21° west of the north point, and that the sun's equator passes $2\frac{1}{2}$° north of the centre of the disc. Spots are carried by the sun's rotation from the east to the west limb in about thirteen days. The centre of this group of spots was nearest the centre of the disc on May 14d. 16h., when it was within 3°. It was then most nearly in line with the earth, but the magnetic storm commenced twenty-seven hours earlier. The spot group was visible to the naked eye for eight out of the thirteen days it could have been seen with the telescope. Its area averaged 1/1500th part of the sun's surface, or about eight times the area of the earth, but it was only half as large as the group of spots of March, 1920.

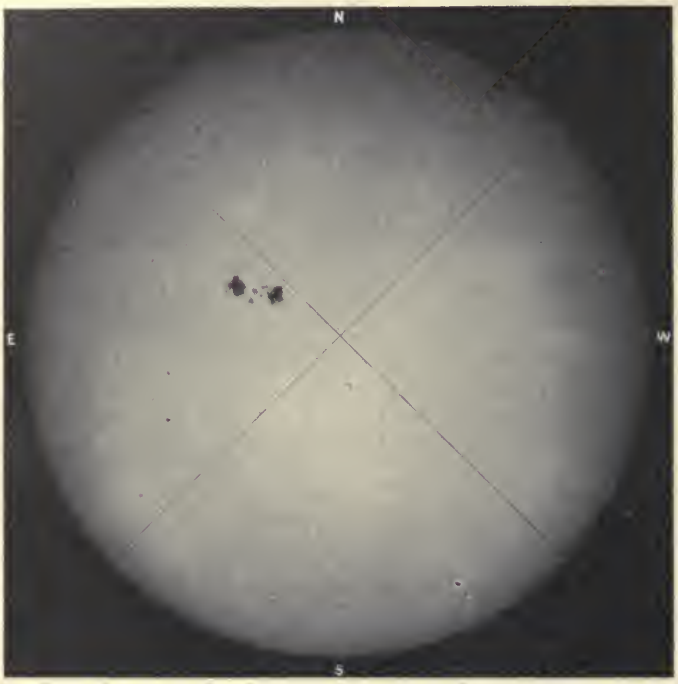

FIG. 1.—Photograph of the sun's disc on May 13d. 9h. G.M.T. Original scale $7\frac{1}{2}$ in. to sun's diameter. By kind permission of the Astronomer Royal.

(b) Sun-spots are nearly always to be found in continual change, especially for a few days following their formation, and it is evident from earlier photographs that this group developed after April 25, and was, therefore, of recent origin. It was first seen at the east limb of the sun on May 8 as a long, irregular spot, nearly 80,000 miles in length, with two principal nuclei; by May 13 these had become the centres of two spots 7° apart in longitude, while the mid-portion of the original spot had changed into a cluster of small ones. It is unusual for a large spot to split up in this manner. Pairs of spots often appear, but they have generally been evolved from two small nuclei. On the photograph of May 9 it will be noticed that the spot is surrounded by bright faculæ. The amount is unusually small for so large a spot, but by the time the group had reached the west limb of the sun the area of faculæ had extended considerably.

(c) The magnetic storm commenced suddenly at 13h. 10m. on May 13. At this time the leading spot was $11\frac{1}{2}$° east of the sun's central meridian and the following spot 19°. The greatest intensity of the disturbance was about 5h. on May 15, at which time the following spot was 3° past the central meridian, while a

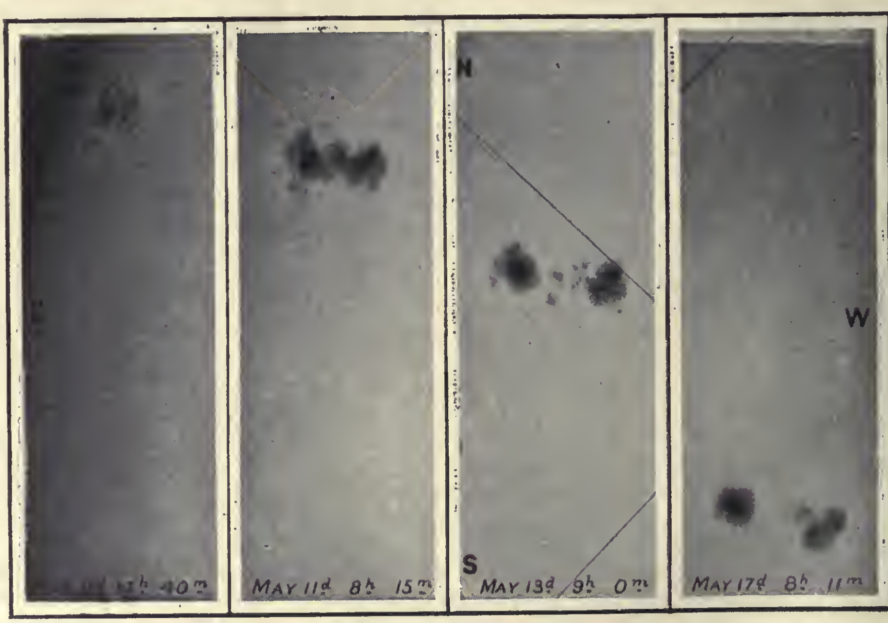

FIG. 2.—Original scale $7\frac{1}{2}$ in. to sun's diameter. Note the foreshortening of the spot near the sun's limb. By kind permission of the Astronomer Royal.

secondary maximum followed at 8h. on May 16. It does not seem possible to associate the disturbance with one or other individual spot, but rather with the group as a whole. In this connection it is of interest to note that minor magnetic disturbances occurred on April 18 and March 21. Some years ago Mr. Maunder showed that magnetic storms tend to recur at intervals of about twenty-seven days, which corresponds to the time taken for the sun to make one rotation relative to the earth. If this sequence is continued we may expect a further disturbance on June 9, when the spot group, if still visible, will be in the same relative position on the sun's disc as on May 13, when the storm commenced.

The general relation between the diurnal variation of the earth's magnetic elements and the sun-spot cycle cannot be doubted. It is better termed the *solar* cycle, for it is well known that the solar prominences, the faculæ and flocculi, and the shape of the corona vary also with the sun-spots in the same eleven-year period. The causes, however, of this terrestrial and solar relation are still obscure, and the magnetic storms in particular offer other difficulties on account of their anomalous occurrence, although on the whole they follow the sun-spot curve. The theory which in general seems best to fit the observed facts is that which assumes a directive stream of charged particles ejected from a restricted area of the sun, most probably in the region of a sun-spot. Opinions differ as to the exact nature of the stream and as to its action on meeting the earth. It is, of course, admitted that such a stream, though it may be a requirement, is not the sole factor in the production of a magnetic storm, the energy of which is to be traced to the earth's own magnetic system, and ultimately to the earth's rotation.

At Mount Wilson Observatory the magnetic polarities of sun-spots are now investigated daily. It will be interesting to see whether this group of spots is associated with exceptionally strong or otherwise abnormal magnetic fields.

Obituary.

DR. G. B. LONGSTAFF.

DR. G. B. LONGSTAFF died on May 7, after a long period of failing health, at his residence, Highlands, Putney Heath. Dr. Longstaff was born on February 2, 1849, and educated at Rugby and at New College, Oxford, where he obtained a scholarship and a first class in natural science. At a very early age his attention was attracted to the study of insects, mainly through the influence of his uncle by marriage, William Spence, of "Kirby and Spence's Introduction to Entomology"; and he was already recognised as one of the most energetic and successful of the younger lepidopterists of his time, when a regrettable accident in the second term of his residence at Oxford, which resulted in the loss of an eye, put an end to his activities in this direction for many years. His later career at St. Thomas's Hospital, where he was awarded the Mead medal, was highly distinguished, and in later life, besides taking an active part in philanthropic and municipal work, he represented Wandsworth on the London County Council for fourteen successive years.

Much attention also was devoted by Dr. Longstaff to the scientific aspect of statistics, and his well-known work on this subject ("Studies in Statistics") was published in 1891. His long-dormant interest in entomology was revived by a tour in India and Ceylon in the winter of 1903–4; and in later years flying visits were made by him to almost every accessible part of the world in company with his accomplished second wife (*née* Mary Jane Donald, well known as an authority on recent and fossil mollusca). The energy and acumen with which insects were collected and observed on these trips may be estimated by the fact that Dr. Longstaff enriched the museum of his old university by at least 14,000 specimens, and the value of this generous contribution is greatly enhanced by the full and accurate data attached to every one of them.

The gratitude of all entomologists is also due to Dr. Longstaff for the finely illustrated and most pleasantly written narrative of these collecting trips which appeared in 1912 under the title of "Butterfly Hunting in Many Lands." The numerous and valuable observations on the bionomics of the butterflies met with in the regions visited—their flight, resting habits, seasonal forms, mimicry, and sexual scents, to which last-named subject Dr. Longstaff devoted special attention—are embodied in the last chapter of this fine book, which is supplemented by an equally valuable series of papers on the same questions by the late Fritz Müller, here presented for the first time in English.

Dr. Longstaff was a highly appreciated member of many learned bodies, and had been vice-president of the Royal Statistical Society and of the Entomological Society of London; and the loss of his commanding presence and genial address at their meetings will long be regretted by his fellow-members, as well as by his numerous friends in private life.

WE notice with much regret the announcement in the *Times* of the death of DR. EDWARD B. ROSA on Tuesday, May 17, at the age of fifty-nine years. Dr. Rosa had been connected with the U.S. Bureau of Standards since 1901, and from 1910 onward he held the position of chief physicist at the bureau.

Notes.

At a special meeting of the Institution of Electrical Engineers, to be held on May 31, a proposal will be submitted to the members that the institution shall petition the Privy Council for a charter of incorporation. More than forty years ago, when the institution was a small and struggling society, it applied for a charter, but the application was successfully opposed by the Institution of Civil Engineers. Now that the importance of electrical engineering to the community is recognised, and the good work that the institution has done in developing electrical science and its applications is well known, there is no reason to anticipate that there will be any opposition to the grant of a charter. The only point where discussion is likely to arise is in connection with the clause which proposes to confer upon corporate members of the institution the right to use the designation "chartered electrical engineer." We take it that the object of this clause is to distinguish between an electrical engineer and a man who, having some slight technical qualification, calls himself one. We think the proposal unnecessary. The public recognises that the letters M.I.E.E. are a complete qualification.

Telephonic communication has now been established between Cuba and the United States by three separate cables, each of which is more than a hundred miles in length and is submerged to a depth of 1000 fathoms. Owing to the large electrostatic capacity of submarine cables distinct speech through them would be impossible were not the circuit made inductive so as to secure the practically "distortionless circuit" first described by Oliver Heaviside. In the submarine portion of the London-Paris telephone circuit "lumped inductance" is added by inserting Pupin inductance coils at short intervals. In the Havana and Key West cables the copper core is surrounded by a continuous spiral of fine iron wire insulated by a sheathing of gutta-percha. The inductive loading is thus continuous, and so the necessary mathematical conditions can be more accurately fulfilled. Above the gutta-percha is wound a copper tape as a protection against the attacks of the teredo. Over this shield is wound a further copper tape, which forms the return half of the telephone circuit of each cable. The specifications for the cables were prepared by Sir William Slingo, formerly Engineer-in-Chief of the British Post Office, in conjunction with the Western Electric Co.

We learn from the publication, *Radium*, that Mme. Curie left France on May 7 on a visit to the United States, the main purport of her visit being to receive a gift of one gram of the element radium from the women of the United States. The gift was organised by Mrs. William Brown Meloney, the editor of the *Delineator*, and carried into effect by the Marie Curie Radium Fund Committee. From a report in the *Times* of May 21 it appears that this presentation was made to Mme. Curie at the White House, Washington, at the hands of President Harding. In an eloquent and felicitous address the President referred to the benefits conferred upon humanity by discoveries in science. It is, as he said, given to relatively few to make great discoveries, and the recognition given to those who do so is often meagre enough. In a happy phrase he reminded his audience that "the great things achieved by great minds would never have been wrought without the inspiration to successful effort, and success in turn enables the outgiving of benefits to millions whose only contribution has been the power of their united appeal." We understand that Mme. Curie is to be the recipient of several honorary degrees on the occasion of her visit to America.

The importance of regular meteorological reports from Greenland for the forecasting services of Western Europe, and, indeed, for that of Canada also, has been recognised for some years. The question of these reports was discussed at the meeting of the International Commission for Weather Telegraphy which was held in London in November last, and the Commission decided unanimously that "the establishment at the earliest possible date of a high-power radio-telegraphic station in Greenland is of the utmost importance to the meteorology of Western Europe, and, further, it is of such importance as to warrant the international provision of funds for maintaining it." It is probable that the provision of such a station by the Danish Government will be made at an early date. When this station has been provided it will be possible to make a definite use in weather forecasting in Europe of meteorological observations from Canada and the United States. Hitherto the gap between the European and American observations has been so great that meteorologists have been unable to justify the expense which would be involved in regular cable messages from America to England.

Dr. E. J. Russell, director of the Rothamsted Experimental Station, has been appointed a foreign corresponding member of the Reale Istituto Lombardo di Scienze e Lettere di Milano.

Dr. F. L. Golla will deliver the Croonian lectures of the Royal College of Physicians on Tuesdays and Thursdays, June 9, 14, 16, and 21, at 5 o'clock, upon the subject of "The Objective Study of Neurosis."

Notice is given by the Institute of Physics that the first examination of candidates for the associateship of the institute will be held at the latter end of September next. Forms of application are obtainable from the Secretary, 10 Essex Street, W.C.2. Applications for entry must be received before June 15.

A public meeting arranged by the National Union of Scientific Workers will be held in the Botanical Theatre, University College, Gower Street, on Monday next, May 30, when Prof. L. Bairstow will speak on the subject of "The Administration of Scientific Work." The chair will be taken at 8 p.m. by the Right Hon. Viscount Haldane.

The Principal Trustees of the British Museum have appointed Dr. W. T. Calman to be deputy keeper in the department of zoology. Dr. Calman, who

graduated as a Doctor of Science at St. Andrews University, has been in charge of the Crustacea at the Natural History Museum since 1904, and is the author of "The Life of Crustacea" and of numerous articles on this group.

A meeting on the subject of "Constructive Birth Control: Its Ideals and Helpfulness to the Individual and to the Race" will be held at Queen's Hall on Tuesday next, May 31. The chair will be taken at 8.30 by the Right Hon. G. H. Roberts, and among the speakers will be Dr. Jane L. Hawthorne, Dr. C. Killick Millard, the Right Hon. J. M. Robertson, Admiral Sir Percy Scott, and Dr. Marie Stopes.

The Ottawa Field-Naturalists' Club has decided to open a subscription list for a permanent memorial to the late Prof. John Macoun, naturalist of the Geological Survey of Canada, who died at Sidney, British Columbia, on July 18, 1920. The wide field of work to which Prof. Macoun devoted his life is known to many naturalists. He specialised particularly in botany, and was the founder of the Canadian National Herbarium. Other sciences, however, especially zoology, were also greatly enriched by him. He will be remembered as the great pioneer in Canadian natural history. The memorial will take the form of a portrait to be hung in the Victoria Memorial Museum, which will be executed by Mr. Franklin Brownell, of Ottawa. The expenses in connection therewith will be about 700 dollars, and subscriptions, which should be forwarded to Mr. Arthur Gibson, Dominion Entomologist, Ottawa, are invited.

The third meeting of the Council of Agriculture for England, constituted by the Ministry of Agriculture and Fisheries Act, 1919, will be held at the Middlesex Guildhall, Westminster, S.W., on Friday, May 27. The proceedings will begin at 11 a.m. and will be open to the public. The Earl of Selborne, K.G., will be in the chair. The purpose of the council is to provide an opportunity for the discussion of matters of public interest relating to agriculture and other rural industries by persons representing the various interests of the industry from all parts of the country. Several interesting resolutions will be considered, among which may be mentioned two to be moved by Sir Douglas Newton, dealing with the facilities of railway goods stations for the rapid transit of soft fruit and other perishable produce. The question is especially difficult at the present time, when railway services have to be curtailed.

In connection with the presentation on June 29 of the John Fritz medal to Sir Robert Hadfield, which was announced in Nature of May 5, it may be of interest to record the events which led to the institution of this medal. In 1902 a number of friends and associates of John Fritz, the American engineer who brought about great changes in the iron and steel industry in the United States, decided to celebrate his eightieth birthday by establishing a fund, the income from which should be used to strike annually a John Fritz medal for scientific and industrial achievement in any field of pure or applied science. A committee consisting of representatives of the American Societies of Civil and Mechanical Engineers and the American Institutes of Mining and Electrical Engineers was appointed, and an impression of an appropriate design was presented to John Fritz at a great dinner given in the Waldorf Hotel, New York. After the die had been completed the committee continued in existence as the John Fritz Medal Fund Corporation. One member of each of the societies instrumental in founding the fund is now elected annually to serve on the committee for a period of four years; the members of the committee also act as a board of award. The medal, which is of gold, is awarded annually, without restriction on account of nationality or sex, and it is accompanied by a diploma reciting the origin of the medal and the specific achievement for which the award is made. The first award, in 1902, was made to John Fritz, and the second, in 1905, to Lord Kelvin, "for work in cable telegraphy and other general scientific achievements." Since then an award has been made every year with the exception of 1913, and the list of recipients contains such well-known names as George Westinghouse, Dr. Alexander Bell, Thomas A. Edison, Sir William H. White, and Elihu Thomson.

The second issue, that for April, of the *Antiquaries' Journal*, the journal of the Society of Antiquaries of London, is fully up to the level of the first number, and the publication marks a distinct advance in the popularisation of the science of archæology. Mr. A. Leslie Armstrong announces the discovery of engravings found at Grime's Graves, Norfolk, on flints associated with a series of flint implements of Le Moustier type, bone tools, and pottery, on a level immediately overlying glacial land. One is a naturalistic representation on flint-crust of a stag or perhaps an elk. The authorities at the Natural History Museum regard this animal as an elk, known in America as "moose." In the discussion which followed, the president suggested that the art of the engravings seemed to be of the same character as the French cave series, though he would not say the resemblance was conclusive. "In recent years discoveries at Grime's Graves, Northfleet, and elsewhere had reduced the sequence of prehistoric periods to a state of flux. If type, material, and coloration, singly or collectively, meant nothing at all, the whole structure of prehistoric study was undermined. In any case, the Grime's Graves industry did not seem to belong to the ordinary Neolithic period."

In the April issue of *Man* Sir Ray Lankester describes, with illustrations, a remarkable flint implement found lying on the surface of a field within ten yards of the gravel-pit in which the jawbone of Eoanthropus was discovered in 1912. He proposes to call this specimen "the Piltdown batiform," and he expresses the hope that it may be placed with the other Piltdown flints in the Geological Department of the British Museum. He thus sums up the question:—"In my opinion the facts hitherto ascertained do not justify the identification of the period at which Eoanthropus lived with the period at which any of the flint implements discovered in the Piltdown gravel were fashioned, nor do we know enough

to make the assertion that implements of Mousterian or Acheulæan or Chellæan or pre-Chellæan workmanship were *not* manufactured or in use when Eoanthropus flourished. Assuredly we are not in a position to assume either that Eoanthropus manufactured flint implements, or, on the other hand, that he did not do so. To me it seems improbable that Eoanthropus had anything to do with flint implements at all, although more likely that he suffered from them rather than that he benefited by their use."

IN an article on the conditions of cellular immortality (*Sci. Monthly*, vol. xii., No. 4, p. 321) Prof. Raymond Pearl discusses artificial parthenogenesis and tissue culture and the views regarding senescence to which they lead. The life of the unfertilised egg-cell can be prolonged only by fertilisation or by some other stimulus to development. The experiments of Leo Loeb, Harrison, Burrows, Carrel, and others in the culture not only of embryonic, but also of adult, tissues *in vitro* show that the phenomena of senescence do not originate in the cells themselves; for all the essential body-tissues, including heart-muscle, nerve-cells, spleen, connective tissue, and kidney-cells, have been shown to be capable of multiplication indefinitely by mitotic division outside the body. With improved methods Carrel has kept a strain of connective tissue from the chick's heart alive and growing for nine years. There is, therefore, a potential immortality not only of germ-cells, but also of tissue-cells, and senescence is a phenomenon of the differentiated body as a whole, due to the effects of the various types of cells upon each other.

IN the Journal of the Quekett Microscopical Club (vol. xiv., November, 1920) Mr. G. T. Harris describes the Desmid flora of a small area in East Devon, and compares it with that of Dartmoor in order to elucidate the influence of geological beds on the species density of the Desmid flora. Dartmoor is a Palæozoic, semi-mountainous area of extensive peat deposits, great rainfall, and deep bogs; the other, a Triassic, lowland area, with no peat-bogs, moderate rainfall, and unimportant bogs. The numerical results from each area were surprisingly similar, indicating that the factors influencing the richness or poverty of Desmid floras must be sought elsewhere than in the geological beds upon which the habitats stand; and a recent investigation of the Desmid flora of a district on Eocene beds confirms this statement. The species density of the two districts is also practically the same. A systematic list of the species and varieties from the Triassic area, 429 in number, is given. This adds 122 forms to the Desmid flora of Devonshire, bringing it up to a total of about 500 species and varieties. From gatherings made during the winter it would appear that most species in a southern county like Devon pass the winter in the vegetative state.

THE Forestry Commission in a recent report states that up to April it had acquired for planting 97,160 acres of land, of which 36,682 acres are in England and Wales, 54,972 acres in Scotland, and 5506 acres in Ireland. The area of 1586 acres planted under favourable conditions in 1919–20 continues to show satisfactory growth. During the 1920–21 season 6257 acres were planted at seventeen centres in England and Wales, nine centres in Scotland, and twelve centres in Ireland, while new nurseries have been established in various parts of the country. The Commission has published a report of the British Empire Forestry Conference held in London last July, which can be obtained through any bookseller or from H.M. Stationery Office (7*s*. 6*d*.). Leaflets on forest pests—No. 2, *Chermes Cooleyi*; No. 3, The Pine Shoot Beetle; and No. 4, *Hylastes ater*—can be obtained free on application to the Commission at 22 Grosvenor Gardens, London, S.W.1.

THE disposal of the débris from hydraulic mining and its influence on the lower courses of rivers have been urgent problems in California for the last half-century. A monograph on the subject by the late Dr. G. K. Gilbert is published by the United States Geological Survey entitled "Hydraulic Mining Débris in the Sierra Nevada" (Professional Paper 105). The material washed from the hillsides is carried by the creeks and rivers, and eventually finds lodgment in the lower reaches of the streams and during floods on the riparian lands, thus doing a considerable amount of harm to navigation and agriculture. For these reasons hydraulic mining has been severely restricted for many years. The bays of the San Francisco system have been sounded and mapped more than once, and comparisons made between early and recent maps show that the areas of the bays have been much reduced by the seaward growth of muddy shoals. Since the discovery of gold and the beginning of hydraulic mining more than 1,000,000,000 cubic yards of material have been deposited in the various bays. Dr. Gilbert made careful researches on the effect of this shoaling and diminution of area on the tidal currents and depths of water on the Golden Gate bar. The crest of the bar shows a retreat towards the land, but no reduction in depth since 1855, and the navigability of the bar has apparently not yet been affected.

IN the Journal of the Franklin Institute for April Mr. A. H. Armstrong considers the economic aspects of railway electrification in the United States. He points out that at the present time we are facing the facts of an eight-hour working day with overtime costing 50 per cent. more, greatly increased wages, fuel prices at levels never before reached, and maintenance costs at almost prohibitive values. With no immediate prospect in sight of any material reduction in the price of labour, its output must be increased, and electric operation effects this both on the railway line and in the workshop. The electrification of railways is a very costly operation, but the saving in operating expenses enables a reasonable return to be obtained on the capital expended. The argument for electrification, however, rests on a broader foundation than this. The national prosperity of America is bound up with the future growth of its transport system, and this growth depends on the adoption of electrification. An incidental advantage of electrification is that it would save one-sixth of all the coal mined in the United States.

THE fourth annual general meeting of the Society of Glass Technology was held at University College, London, on April 20, when Dr. Morris W. Travers was elected president in succession to Mr. S. N. Jenkinson. The new president delivered an address on the importance of quantitative investigation in dealing with technical glass problems. The speaker directed attention to the fact that the late Lord Moulton, who was to have presided at the society's dinner that evening, had brought about a great improvement in the efficiency of explosives factories by applying quantitative investigation to the processes conducted in them. The energy balance-sheet of a factory was as important as its financial balance-sheet, and the efficiency of a furnace, for instance, should be accurately known so that a full account could be given of all heat which entered it. This principle was illustrated by application to several furnace problems. There was also a wide field for investigations bearing on the nature of glass, and recent work had shown that glass in the solid condition resembled the elastic gels rather than the liquids. A paper on automatic glass-feeding devices was communicated by Messrs. G. Dowse and E. Meigh, and the society's third annual dinner followed. During the course of the evening the president referred to the proposed legislation affecting the industry, and maintained that the total prohibition of the importation of all chemical glassware except under licence was essential to that branch of the industry. Electric lamp bulbs should also have been included in the Bill. Assistance would be necessary if the manufacture of these articles were to be continued in this country.

MESSRS. G. E. STECHERT AND CO., 151 West 25th Street, New York (London: 2 Star Yard, Carey Street, W.C.2), have sent us a copy of their catalogue (New Series, xl.) of second-hand books relating to natural history. It contains some hundreds of titles, and is classified as follows:—General Natural Science; Agriculture, Forestry, Farming; Botany; Zoology; Ornithology; Ichthyology; Entomology; Gardening; and Supplement. The prices asked (in American dollars) appear to be very moderate.

AN interesting little catalogue (No. 414) of nearly four hundred works (books and engravings) on the topography of Kent and Sussex has just been issued by Mr. F. Edwards, 83 High Street, Marylebone, W.1. It will doubtless appeal to residents in the two counties named and to many others.

Our Astronomical Column.

COMETS.—It appears that Dubiago's comet was discovered by him at Kasan on April 24, and observed at Pulkovo a few days later. It has now been observed in England by Dr. Steavenson, whose observations enable the orbit to be improved. This has already been done approximately with the following result:—

T 1921 May 7·177 G.M.T., ω 100° 13′, ☊ 65° 58′, i 22° 20′, log q 0·0481.

Ephemeris for Greenwich Midnight.

	R.A. h. m. s.	N. Decl. ° ′	Log r	Log Δ
May 28	9 38 57	35 52	0·0680	0·0172
June 1	10 0 27	33 18	0·0756	0·0179
5	10 20 55	30 30	0·0840	0·0203
9	10 40 22	27 32	0·0933	0·0250
13	10 58 42	24 27	0·1032	0·0318
17	11 16 3	21 20	0·1137	0·0406

Its total light is probably equal to a 9th magnitude star; it should be readily visible in an ordinary telescope in the absence of the moon.

The errors of the ephemeris of comet Pons-Winnecke have become so large that it is well to give the revised orbit lately received from Prof. Crawford and Miss Levy, with the ephemeris, for Greenwich midnight, deduced from it.

T 1921 June 12·95 G.M.T., ω 170° 34′, ☊ 97° 51′, i 18° 50′, log q 0·01703, e 0·6779, period (assumed) 5·8 years.

	R.A. h. m. s.	Decl. ° ′	Log r	Log Δ
May 27	19 35 27	43 16 N.	0·0272	9·2698
31	20 16 47	39 36	0·0230	9·2226
June 4	21 0 39	33 52	0·0198	9·1818
8	21 44 21	26 4	0·0178	9·1537
12	22 24 42	16 37	0·0170	9·1446
16	23 0 20	6 50 N.	0·0175	9·1572
20	23 31 5	2 14 S.	0·0192	9·1881
24	23 56 42	9 55 S.	0·0221	9·2295

After this the comet will travel south rapidly; it should be observable in the southern hemisphere until September.

THEORY OF JUPITER'S SATELLITES.—Prof. Sampson's tables of Jupiter's satellites have been in use in the national ephemerides for several years, but the theory on which they were based has only just appeared in print, being vol. lxiii. of Memoirs of the Royal Astronomical Society. The author commences with a review of the work of Laplace, Delambre, Damoiseau, and Souillart; he explains that the discordances that still exist between the tables and observation are due to the fact that in deducing the fundamental elements with the aid of the older theories it was assumed that only the leading terms of these would be involved. It was discovered (too late to alter the tables) that some secondary terms in the older theories were so seriously wrong that the tables are sensibly affected. One such error may affect the time of an eclipse of Satellite IV. by 140s.

The elements at the present day were derived chiefly from the Harvard photometric observations of eclipses. These permit of the deduction of an exceedingly accurate value of the equatorial semi-diameter of Jupiter; the mean of the Harvard and Durham discussions is 18·927″.

The adopted value of Jupiter's mass is 1/1047·35, but it is noted that a discussion of recent measures and photographs in conjunction with the theory leads to the value 1/1047·0. It would, however, be rash to alter the accepted value, which rests largely on the perturbations of minor planets and the comet Pons-Winnecke.

One advantage of the delay in publishing the theory is that it has enabled a list to be given of the errata and omissions that have been detected. One such was found soon after the tables were printed, and a supplementary page was issued.

Mr. Innes directed attention to two omitted terms; one, due to the effect of the sun on Satellite IV., has a coefficient of 7·6″. The other is a long-period term; period for III. 26½ years, coefficient about 6″. The values for IV. are not very different.

An Early Chellean Palæolithic Workshop-site at Cromer.

AT a meeting of the Royal Anthropological Institute held in the rooms of the Royal Society, Burlington House, on May 3, Mr. Reid Moir exhibited a large collection of ochreous flint implements, cores, and flakes recovered upon a limited area of foreshore exposed at low water at Cromer, Norfolk. These specimens are remarkable not only for their brilliant and arresting ochreous coloration, but also because of the large and massive size of many of the artefacts. Many of them are evidently fashioned for comfortable prehension, but it is clear that the hands of the ancient Cromerian people must have been much larger than those of modern man. Several examples of Early Chellean implements, with coarse flaking upon the upper and lower surfaces, have been found at the Cromer site, associated with rostro-carinates, choppers, scrapers, points, partly finished specimens, cores, and flakes.

It is evident that an actual workshop-site of Early Chellean age is represented at Cromer, and from its position appears to be referable to the lowermost stratum of the Cromer Forest Bed series of deposits. The Cromer Forest Bed strata are generally regarded as of Upper Pliocene age, and it seems, therefore, that the earliest Chellean implements—such as are usually found in river-terrace gravels—must in East Anglia be regarded as of Pliocene date. It is of interest to note that the massive human fossil jawbone found at Heidelberg, in Germany, was supposed to be of about the same antiquity as the Cromer Forest Bed. The individual represented by this jawbone would appear to have been of almost gorilla-like size and strength, and it may be that the massive Cromer implements which have been found were made by people of the Heidelberg type.

An animated discussion followed the reading of the paper. Prof. Arthur Keith, past-president, who was in the chair, said that while it would be impertinent for him to attempt to criticise Mr. Reid Moir's communication, he considered it of outstanding importance in the study of the antiquity of man in this country. This site would appear to be the most ancient workshop-floor which had yet been discovered. Sir William Boyd Dawkins said that no geological evidence had been brought forward for the relation of the flints on this site with the Forest Bed series; they were no more than a foreshore accumulation of flints which differed in no way from other flints found on the foreshore along the whole East and South Coast. Further, it was assumed that the Forest Bed fauna was Pliocene; but it had been shown more than forty years ago that the Forest Bed series included recent mammalia absent from the Pliocene deposits of France and Italy, and, therefore, they should be regarded as Early Pleistocene.

Sir E. Ray Lankester said that the use of the terms "Pliocene" and "Pleistocene" was purely arbitrary, and did not affect the facts. These specimens were quite unlike foreshore flints in their large size, their flaking, and their coloration. Mr. S. Hazzledine Warren denied that any evidence had been brought forward in support of the very definite assertion of date, and it was his opinion that if a boring were made at the base of the cliff, as had been suggested, nothing similar to the conditions on the foreshore would be found at the base of the Forest Bed series. Mr. Haward considered the site represented merely an outcrop of one of the zones of flints which are found sloping down to the sea in the neighbouring cliffs. Mr. Barnes said that the case was not made out. The number of implements was small, while a flake afforded little as a criterion of human manufacture. It was essential that a boring should be made at the base of the cliff. Mr. Reginald Smith, on the other hand, maintained that Mr. Reid Moir had made out a *prima-facie* case; it was only the question of provenance which gave rise to doubt. In referring to the disproportionate number of flakes on the site, he mentioned one of the floors investigated at Swanscombe, on which no implements, but only a large number of flakes, had been found.

The series of humanly fashioned flints collected by Mr. Reid Moir is to remain on exhibit for one month in the rooms of the Royal Society, Burlington House, where the specimens can be seen and examined by those interested.

Hydrology of the Western States of North America.[1]

By DR. BRYSSON CUNNINGHAM.

THREE Water Supply Papers, prepared under the direction of the United States Geological Survey, contain features of interest respecting the natural conditions which prevail in the undeveloped territory between the 108th and 118th meridians of west longitude.

(1) A sequence of devastating floods which swept the counties of southern California in January, 1916, is described in Water Supply Paper No. 426, with records of the precipitation, run-off, and attendant phenomena. The rainfall was heaviest and its effects most disastrous in San Diego County, which for nearly a month after the storm was cut off from communication with the rest of the State. The mean precipitation for the period January 14–30, in different parts of the county, ranged from 20 in. to 30 in. The normal annual rainfall at San Diego is in the neighbourhood of 10–15 in. As a result of the downpour the Lower Otay Dam, forming part of the reservoir system for the city of San Diego, was swept away and the Sweetwater Reservoir developed serious fractures. Twenty-two lives were lost in the flood from the former reservoir. A huge wall of water, variously described as from 6 ft. to 20 ft. in height, rushed down the valley, covering the distance from the dam-site to Palm City (about ten miles) in forty-eight minutes, and carrying everything before it. An impressive idea of the devastated area is obtained from the photographs which illustrate the report. There is also a large-scale map of the district.

(2) Upon the borders of the States of Utah, New Mexico, and Arizona lies an area of reservation, known as the Navajo Country, set aside for indigenous Indian tribes. It is a region of which very little hitherto has been known, and it remains more or less in a primitive condition. The area is considerable, about 25,725 square miles; it is the most exten-

[1] (1) "Southern California Floods of January, 1916." By H. D. McGlashan and F. C. Ebert. Water Supply Paper No. 426. (2) "The Navajo Country." By Herbert E. Gregory. Water Supply Paper. No 380. (3) "Geology and Water Resources of Big Smoky, Clayton, and Alkali Spring Valleys, Nevada." By Oscar E. Meinzer. Water Supply Paper No. 423. (Washington: Government Printing Office 1917.)

sive tract of undeveloped reservation land within the United States. This area forms the subject of a geographical and hydrographical reconnaissance by Mr. Gregory, whose report is embodied in Water Supply Paper No. 380.

The exploration of a little-known region has considerable attractions for the adventurous, and Mr. Gregory in a personal introductory note confesses to its powerful appeal. The Navajo country, he points out, contains the remnants of an almost extinct race whose long occupation of the district is recorded in ruined dwellings and abandoned fields. It is true that roads have been established along selected routes, but by far the larger portion of the territory is accessible only by trails, and in the rougher areas no recognisable tracks are to be found.

The country contains many extremely interesting features, topographical, geological, and hydrographical. The 200 pages of the report are replete with valuable notes on the natural resources of the district, and indicate a careful and painstaking investigation. Topographically, the country forms part of the Colorado plateau, a region of flat-lying or slightly tilted rocks, cut by cañons and surmounted by mesas and buttes. "So numerous and so closely interlaced are the cañons in some portions of this singular region that they have displaced all but scattered remnants of the original plateau, leaving narrow walls, isolated ridges, and spires so slender that they seem to totter on their bases, shooting up to an enormous height from the vaults below."

The most inaccessible, least known, and roughest portion of the reservation is a region of bare red sandstone rock forming a plateau, known as the Rainbow Plateau, intersected by innumerable cañons, some of which are bridged by natural arches. One of them is a symmetrical semi-circular curve with a span of 274 ft. It gives its name of "The Rainbow" to the plateau.

The Navajo Indian is given a fairly good character; he is vigorous, intelligent, and capable of hard work provided it be not too continuous. He is, however, independent towards those who engage his services, and liable to take himself off. "He will help himself to interesting trinkets and to food, but may be trusted with valuable things and with important missions."

The report is well illustrated by photographs and maps.

(3) Big Smoky Valley, the subject of Water Supply Paper No. 423, is a typical Nevada desert valley—a plain hemmed in by mountain ranges and underlain by porous rock-waste eroded therefrom. It once contained two large lakes, one 40 miles long and 9 miles in maximum width in the upper part of the valley, and the other about 22 miles long by 5½ miles wide in the lower part. The depth of the former ranged to as much as 170 ft., and of the latter to 70 ft. The existence of these lakes is deduced from shore features which are still in existence. The climate is distinctly characteristic of an arid tract, the annual rainfall being generally about 6 in. or 7 in., or even less. The valley is but sparsely populated, and the settlers are principally engaged in mining or milling. The report contains maps, diagrams, and photographs.

The Plaice Fishery in the Belt Sea and Neighbouring Waters.[1]

THE sea-fisheries of Great Britain, though perhaps of less importance to the prosperity of the country than the supply of coal, are nevertheless of vital interest in more ways than one. Consequently, anything bearing on the problems connected with them, especially as to their permanence, ought to awaken interest in all who have practically studied this intricate subject, as well as to arrest the attention of the legislators and the public. Few nations have done more in proportion to their populations than the Danes in unravelling various problems of the sea-fisheries, and were it only for the single case of the remarkable life-history of the eel as elucidated by Dr. Johs. Schmidt, their labours merit careful attention as well as commendation.

The Report of the Danish Biological Station for 1920, by the experienced expert Dr. Petersen, who is well known in fisheries researches and for transplanting so successfully the plaice into the Limfjord, discloses a new feature in the plaice-fishery of the Belt Sea and neighbouring waters. No fish in the North Sea, indeed, has given more solicitude to scientific investigators and the fishing industry than the plaice, which, after the twenty years' labours of the International Fisheries Council, was singled out as the only form requiring legislation. Dr. Petersen, the author of the Danish report, hitherto has held the belief that it was possible to produce impoverishment of certain areas by over-fishing, though at the Dundee meeting of the British Association in 1912, when "impoverishment" was challenged, he declined to give an opinion, nor did anyone present support it. Dr. Petersen, indeed, had in former years pointed out the decline of a Danish plaice-fishery, but, as Dr. H. M. Kyle afterwards proved, that was a misapprehension. Now in this report of 1920 we have the remarkable admission that the intensive plaice-fishing, first by gill-nets and then by seines with otter-boards (which increased greatly from 1912 to 1919) worked from motor-boats in the Belt Sea and neighhourhood, has resulted, not in the impoverishment of the area, but in the more rapid growth of the plaice of to-day. The plaice now fished are younger, larger, and better fishes than formerly, though they are fewer on a given hectare, but the yearly yield is larger. Further, in the words of Dr. Petersen, "the plaice got formerly we did not care to eat . . . now we regard them as delicacies."

Dr. Petersen supports his views by the Fiskerei-Beretnings statistics for twenty years, which show that this intensive fishery has had the effect of increasing the weight of plaice from an average of 5 kg. per score to 10 kg. per score. The original dense old stock has been fished out, and a new, quick-growing race, fewer in number per hectare, has fortunately appeared. "It is like a lawn which is cut many times a year in lieu of once every second year; the latter method produces old, bad grass only, the former gives much more and better grass, but calls for much more work." Instead of 500 tons before 1900, the fishery of the area now produces 1000 tons; indeed, in 1912, 1913, and 1919 the yield was about 3000 tons, and valued at 3,000,000 kroner.

In 1900 the fishing in the Great Belt at 22 m. produced many undersized plaice amongst the larger forms of 40 cm., and there was a majority of males. In 1920 there were few undersized forms, and generally they were larger and heavier than before, the larger being similar to the larger in 1900, and

[1] "On the Stock of Plaice in Relation to the Intensive Fishing of the Present Times in the Belt Sea and other Waters." Report of the Danish Biological Station to the Danish Board of Agriculture, xxvii., 1920. By Dr. C. G. J. Petersen. (Copenhagen: G. E. C. Gad, 1921.)

the females were in the majority. The three- and four-year-olds were on an average larger than the old plaice of former times, the latter being slow-growing and consuming the available food without much increase in bulk. Thus the intensive fishing had improved the growth of the plaice in the area. Further, in the small waters of the Belt the young plaice have but a short distance to travel to reach places where rapid growth occurs, whereas in the Kattegat and the North Sea it is otherwise. In these deep basins of the Belt, moreover, gill-net fishing south of Faaborg has hindered over-population. The food of the plaice in the area consists largely of *Macoma baltica, Abra alba,* and the annelid Nephthys.

Dr. Petersen anticipates that similar results to the foregoing in larger areas might be attained by transplanting, and he would recommend prohibition against landing plaice in the spawning season. He places much weight on the supply of food for the plaice, old and young, for he thinks this is variable and possibly deficient; but it has long been demonstrated that the supply of food on the bottom, in mid-water, and near the surface is everywhere both persistent and ample, and no effort of man can, as a rule, modify it beyond low water. The contrast between the sea and the fresh-waters in this respect is often misunderstood. Taking a broad view of Dr. Petersen's observations, and without placing undue weight on the effects of intensive fishing in the Belt Sea, they simply bear out the marvellous ways of Nature in the ocean, especially in connection with the food-fishes, the recuperative powers of which are independent of artificial interference. Some may clasp and nurse the phantom of "impoverishment" of this or that place (seldom located), but Nature, unheeding, quietly answers by her annual swarms of young and by the rich and perennial harvest of food-fishes which everywhere rewards industrial energy. W. C. M.

The Melbourne Meeting of the Australasian Association.

I.

It was arranged that the fifteenth meeting of the Australasian Association for the Advancement of Science should be held at Hobart on January 5–11 last, when, on December 18, passenger communication with Tasmania was cut off by a strike, and eventually it was decided to hold the meeting at Melbourne. By this unavoidable decision a grave disappointment was inflicted on the Tasmanian executive, who had worked for months at the organisation of the meeting, and also on Australians who desired to combine a holiday with participation in the science congress. Further, it meant that a great strain was placed upon the Melbourne officials, who had to arrange local details at short notice after a particularly strenuous time during midsummer. Nevertheless the meeting was one of the most successful ever held, and members have especial reason to be grateful to the president of the association (Sir Baldwin Spencer) and to the local secretary (Dr. Georgina Sweet), who, at the head of a band of devoted assistants, worked early and late and thus secured the fine results obtained.

A feature of the meeting was the number and importance of the sectional and intersectional discussions, many of the papers being taken as read in order to afford an opportunity for the interchange of ideas on subjects which are of special importance to the Commonwealth.

During the transaction of business it was decided that the invitation of the New Zealand Institute to hold the next meeting in January, 1923, at Wellington, New Zealand, should be accepted. It was also resolved that meetings in New South Wales, Victoria, or Tasmania shall in future alternate generally with those in the more remote States.

The permanent honorary secretary, Mr. J. H. Maiden, asked to be relieved of the duties of his office as from December 31, 1921, and on the motion of the president a resolution was unanimously carried recording the council's deep appreciation of Mr. Maiden's valuable services to science and to the association during the past fourteen years.

The council made a formal offer of the presidency for the Wellington meeting to Mr. J. H. Maiden, who gratefully acknowledged the compliment, but asked to be excused acceptance of the honour. The name of Mr. G. H. Knibbs, Commonwealth Statistician, vice-president, was then submitted, and he was unanimously elected. Mr. Knibbs has rendered the association invaluable service during a long period of years. Mr. E. C. Andrews, Government Geologist of New South Wales, was unanimously elected to the office of permanent honorary secretary as from January 1, 1922.

The council recorded its deep sense of the value of the experimental work in aeronautics of the late Laurence Hargrave, which has led to such remarkable results in the evolution of aviation, and proved of such immense importance during the recent war.

Mueller Memorial Medals.—It was decided to award two medals, as follows:—(1) Mr. R. T. Baker, curator of the Technological Museum, Sydney, in acknowledgment of his eminent services to botany, particularly in regard to Eucalyptus; and (2) Prof. C. Chilton, professor of biology, Christchurch, New Zealand, in acknowledgment of his eminent services to zoology, particularly in regard to the crustacea.

Australian National Research Council.—In 1919 Australia was invited to take part in the formation of an International Research Council. Two representatives of various branches of science were appointed to form a provisional committee, and it was decided to refer the matter of the constitution of the permanent body to the council of the association at the Hobart (Melbourne) meeting. A sub-committee of the latter was appointed to draw up a scheme, which was adopted by the council. It provides that a National Research Council for Australia shall be instituted, consisting of not more than one hundred members, representative of the following branches of science: (1) agriculture; (2) anthropology; (3) astronomy; (4) botany; (5) chemistry; (6) economics and statistics; (7) engineering; (8) geography; (9) geology; (10) mathematics; (11) mental science and education; (12) metallurgy; (13) meteorology; (14) pathology; (15) physics; (16) physiology; (17) veterinary science; (18) zoology. The present provisional council is to meet in Sydney in May of this year to co-opt additional members, and the council so constituted will meet as soon afterwards as is possible. It is empowered to appoint (*a*) such office-bearers as it may determine; (*b*) such standing and special committees as it may deem necessary for national or international purposes; and (*c*) a number of associate members chosen from among the scientific workers in Australia who are deemed likely to confer benefit by their researches. The council will submit a full report of its work and proceedings to the Australian Association for the Advancement of Science at

each meeting of the latter. Until other arrangements are made for the upkeep of the council each member thereof will contribute the sum of two guineas per annum, and each associate member one guinea.

Resolutions of the General Council.

Section A (*Astronomy, Mathematics, and Physics*).—"That as regards the following committees: Solar Physics, Seismology, Terrestrial Magnetism, Tidal Survey, Physical and Chemical Constants, and Longitude—since their methods of working involve international co-operation, these committees should be allowed to lapse, and that the responsibility for carrying on these researches be transferred to the Australian National Research Council."

"That the sum of 50*l.* referred to in the report of the secretary of the Physical and Chemical Constants Committee be approved, and forwarded to Dr. Marie."

Macquarie Island Committee (Sir T. W. Edgeworth David, secretary).—The report was adopted, and the names of Sir Baldwin Spencer, Sir Douglas Mawson, and Capt. J. K. Davis were added to it. The question of re-opening the wireless station at Macquarie Island established there originally by the Australasian Antarctic Expedition under Sir Douglas Mawson with the co-operation of the Commonwealth Meteorological Office has given rise to some difference of opinion, and the meteorologists now give precedence to the establishment of stations at Kerguelen or the Island of St. Paul. The question of re-establishing the wireless station on Macquarie Island must therefore be for the present postponed. The question of creating a zoological and botanical preserve at Macquarie Island is considered to be worthy of favourable consideration.

Committee for the Study of Earth Movements by Horizontal Pendulums (formerly the Committee for Determination of Gravity in Certain Critical Localities).—A preliminary account of the installation and working of the pendulums at Burrinjuck was read before the Royal Society of New South Wales (Journ. Roy. Soc. N.S.W., 1915). The observations have been systematically carried out by Mr. A. Goodwin since the pendulums were first established. Dr. L. A. Cotton, of the University of Sydney, furnished a report; the examination of the records since the preliminary account already referred to has served to explain in large measure the movement which was then regarded as being secular in character. It now appears that the movement is chiefly, if not wholly, seasonal in character and a function of the underground temperature. It is, of course, essential for this work, as well as for the main investigation, to have a detailed geological and topographical survey of the area. This work was taken up about two years ago, and, though far from completion, has yielded important information with regard to the lithographical characters and rock structures of the area under investigation. The general council voted the sum of 105*l.*, already expended in anticipation, together with 50*l.* for the future work of this committee.

The Samoan Observatory at Apia.—The observatory was founded by the Germans in 1902, and is described in the *New Zealand Journal of Science and Technology* (vol. iii., p. 157, 1920) by Dr. C. E. Adams and Prof. Marsden. It is considered most desirable that it should be maintained at pre-war efficiency, and that the cost of it be contributed to by Great Britain, New Zealand, and Australia. A resolution was passed urging upon the Federal and State Governments the importance of the work of the observatory in Samoa and the desirability of contributing 1000*l.* per annum as the Australian share of the cost of upkeep of this institution as an Imperial observatory.

Section C (*Geology and Mineralogy*).—It was decided to form a committee for the classification and correlation of the Carboniferous and Permian rocks of Australia in the place of a committee bearing the name "Permo-Carboniferous of Australia," and another committee, under the title "For the Investigation of the Structural Features and Land Forms in Australasia," to supersede the two committees on "Structural Features in Australasia" and "Physiographic Features of Australasia." The Glacial Phenomena Committee was re-appointed, with Sir Edgeworth David as secretary. The report of the committee was adopted. It consisted chiefly of observations by Mr. Loftus Hills, Government Geologist of Tasmania, on Glacial cirques and moraines in Tasmania, together with "Glacial Notes from New Zealand" by Mr. R. Speight, and brief remarks concerning South Australia by Prof. W. Howchin.

The Kainozoic and Quaternary Climate of Australasia Committee was re-appointed, with Mr. R. Speight as secretary. The Alkaline Rocks of Australasia Committee was also re-appointed, with Prof. E. Skeats and Dr. H. C. Richards as secretaries, and the sum of 50*l.* was voted for expenses.

A report was submitted by Prof. E. Skeats, which embodies references to the work of Prof. H. C. Richards in south-eastern Queensland, and recorded by him in the Journ. Roy. Soc. Queensland (vols. xxvii. and xxx.). As regards Tasmania, Prof. Skeats has supplied a note on the age of the alkaline rocks of Port Cygnet, etc. (Proc. Roy. Soc. Vict., vol. xxix.). The same author wrote a note on the Tertiary alkaline rocks of Victoria for the British Association at its Melbourne meeting in 1914. Since then he has made a number of additional observations which are detailed.

A committee was appointed to collect information in regard to the occurrence of artesian water in Australia, with Mr. S. A. Ward, Government Geologist of South Australia, as secretary.

Section D (*Biology*).—It was decided that a resolution be sent to the Premier of South Australia emphasising the great national and scientific importance of the preservation of native fauna and flora, and congratulating the Government on the legislation recently passed constituting Flinder's Chase, on Kangaroo Island, a national reserve for fauna and flora. Immediate steps should be taken to give full effect to that legislation. The Government is further urged to give full consideration to the unique importance which attaches to the constitution of the whole of Kangaroo Island as a national fauna and flora reserve, as well as to the protection of the land, fresh-water, and sub-aquatic fauna and flora of all the islands in South Australian waters other than Kangaroo Island which are actively used for farming pursuits.

The Ecology Committee was re-appointed with some additional names (Dr. C. S. Sutton, secretary). It was further resolved that a committee be appointed to collect data and initiate a reasonably detailed ecological map of Australia marking out the distribution of the salt-bush and other type-flora.

It was further resolved, on the motion of Sir Baldwin Spencer, that in order to carry out immediately a co-ordinated investigation into the land and fresh-water fauna and the flora of Australia and Tasmania the societies and institutions in the various States be requested to co-operate in the work, and to take such steps as they may deem advisable for carrying out this work, especially in securing in each State the active assistance of

specialists in different branches of botany and zoology.

It was resolved to prepare a bibliography of the botany of those Pacific islands of special interest to Australia under the auspices of a committee consisting of the Government Botanists of Queensland, New South Wales, and Victoria, Mr. J. H. Maiden to be the convener. The sum of 50*l.* was voted in aid of the work.

A brief report was furnished by the Committee for the Biological and Hydrographical Study of the New Zealand Coast (Prof. C. Chilton, secretary). The war has hindered the examination of the collections and the publication of the results.

Section E (*Geography and History*).—It was resolved to urge on the Federal Government that, in the interests of historical and geographical research, it is desirable that steps be taken to continue the work of obtaining translations of all available journals of the early French navigators in Australian waters. It was also resolved to subsidise the work of the investigation of ocean currents, tides, and sand movements on the Australian coasts which has been undertaken, at his own expense, by Mr. G. H. Halligan, late Hydrographic and Supervising Engineer for New South Wales.

Section F (*Ethnology and Anthropology*).—It was resolved that the need for the formation of a Federal Museum for Australia and its territories, and the immediate necessity for securing specimens, historical and ethnological, while they are yet available, be urged on the Federal Government.

Also, that the Federal Government be pressed to endow a chair of anthropology, especially in view of its value in the government of subject races, and that attention be directed to the desirability of investigating and recording the ethnology of the northern part of Western Australia.

Section H (*Engineering and Architecture*).—The council welcomed the general recognition gradually being extended towards the movement for the better planning and development of cities and suburbs, and affirmed that great economic waste exists, and is increasing, consequent upon the ill-planning and absence of regulation for the proper development of cities and suburbs, which will lead to many and costly resumptions to make necessary improvements. The hope was also expressed that State Governments, following the lead of South Australia, may initiate suitable legislation on the subject, including provisions for ensuring full inquiry by means of civic surveys into the needs of existing urban areas.

Section I (*Sanitary Science and Hygiene*).—The Anthropometric Committee (Dr. Mary Booth, secretary) was re-appointed. On the joint recommendation of this Section and Section G (Social and Statistical Science), a committee was appointed to investigate and report on industrial fatigue in Australia.

In connection with Dr. Jean Greig's paper on the problem of the special child and the special school, it was resolved that, in view of the existence of feeble-minded persons and their economic cost to the community, it is desirable that the Government be asked to establish farm colonies and residential homes for the accommodation of these cases, and that in the case of New South Wales the proceeds of the Randwick Orphanage, specially reserved for the care of mentally deficient children, be forthwith applied for that purpose.

It was further resolved that medical inspection be extended so as to include all schools.

Section K (*Agriculture*).—It was decided that the Commonwealth Government be asked to provide funds for the encouragement of the cultivation of cotton in such parts of the Commonwealth as are suitable climatically for its production.

In response to the request of the president of the Agricultural Section of the International Congress of Meteorology, it was decided to appoint a committee to report on the climatic control of wheat production in Australia.

Section L (*Veterinary Science*).—At a joint meeting of the Sections of Hygiene and Sanitary Science, Agriculture, and Veterinary Science Prof. J. Douglas Stewart, dean of the faculty of veterinary science at the University of Sydney, read a paper on "Animal Tuberculosis," the chief object of which was to revive interest in a resolution adopted at the fourteenth meeting of the association recommending the Governments of the States of Australia and of the Dominion of New Zealand to hold a conference of the chief medical and veterinary officers to discuss and report on uniform measures for the control of tuberculosis in cattle and pigs. Owing to the intervention of the war, the council of the association was unable to proceed with the matter.

Abstract of Presidential Address by Sir Baldwin Spencer.

The main part of the address dealt with some aspects of the cultural anthropology of Australian aboriginals, especially with their tribal and social organisation, as illustrating an early stage in the development of human society. In the remainder of the address the origin of the aboriginals and their relation to other races were discussed and a theory of the origin of their complex culture was suggested.

The question of the independent origin of similar inventions, beliefs, and customs was dealt with, and evidence from both the zoological and anthropological sides was brought forward to show the possibility of this. The remarkable homogeneity of all Australian tribes, even with regard to the details of their social organisation, gives no suggestion of outside influence. This homogeneity, existing side by side with the most remarkable differences in skull measurements, customs, beliefs, and arts revealing an extraordinary range of variability, presents a difficult problem quite insoluble on the theory of interactions of various immigrant peoples reaching Australia at different times.

The statement of Prof. Keith and others that the Australian race might have served as common ancestors for all modern races may be understood on the theory that it is the survivor of such a one that has been isolated for long ages in Australia, and has been practically uninfluenced by contact with other peoples. In conclusion, reference was made to the suggestion of Bateson that perhaps "the course of evolution may be regarded as an unpacking of an original complex which contained within itself the whole range of diversity which living things present," and it was suggested that in the characteristic marsupial fauna and in the aboriginals of Australia we have a remarkable example of such an unpacking. This has led, without any outside influence, to the development, on one hand, of mammalian forms along lines parallel with those pursued by higher forms so far as fundamental features are concerned, but controlled at the same time by some factor or combination of factors that has determined the retention of their marsupiality; on the other, it has led to the independent development of a race of human beings along lines parallel with those pursued by other early races of humanity from Mousterian to Aurignacian times, but again always controlled by some factor or combination of factors that has prevented them from developing into anything higher than men of the Stone age.

(*To be continued.*)

University and Educational Intelligence.

CAMBRIDGE.—Honorary degrees are to be conferred on the Prince of Wales, Marshal Foch, Admiral Sims, and Lord Plumer on May 31. The Crown Prince of Japan received an honorary degree on Wednesday, May 18.

The voting on the alternative schemes—(1) admitting women to membership of the University with limited rights or (2) granting them merely titular degrees—is to take place on June 16.

A lecturer is to be appointed in physics as applied to medical radiology.

The first Ph.D. degree has been approved, Mr. C. G. L. Wolf, of Christ's College, being the first successful candidate.

The examination in anatomy in the Natural Sciences Tripos is to be on a wide scale to cover the general morphology of vertebrates, a general knowledge of vertebrate (including human) embryology, and a special knowledge of the morphological side of human anatomy.

EDINBURGH.—The following lecturers have been appointed as readers in the Faculty of Science: Dr. H. S. Allen in physics, Dr. R. Campbell in petrology, and Dr. L. Dobbin in chemistry.

Dr. Beard, lecturer in comparative embryology, has resigned for reasons of health, and Dr. Balsillie, on being transferred to the Royal Scottish Museum, has resigned his lectureship in chemistry.

It has been resolved to re-institute the special tutorial course in German for students of science.

It was reported that the new Ordinance for Degrees in Pure Science (Ordinary and Honours) had been approved by his Majesty in Council, and had now come into force.

LONDON.—A lecture will be given at King's College on Thursday, June 9, at 5.15 p.m., by Prof. Einstein on "The Development and Present Position of the Theory of Relativity." The chair will be taken by Viscount Haldane. A charge of 2*s*. 6*d*. will be made for admission, and the proceeds will be given to the Imperial War Relief Fund. The lecture will be delivered in German. Tickets can be obtained on application to the lecture secretary at the college.

The following advanced lectures addressed to students of the University and to others interested in the subjects have been arranged. Admission is free, without ticket:—A course of four lectures on "Recent Developments in Legislation for the Prevention of Disease," by Dr. Charles Porter, at University College at 5.30 p.m. on May 30 and June 3, 6, and 10. A course of four lectures on "Some Actions of Foodstuffs in the Production and Treatment of Disease," by Prof. E. Mellanby, at the Royal College of Surgeons, Lincoln's Inn Fields, W.C.2, at 5 p.m. on June 6, 7, 13, and 14. A course of three lectures on "Recent Advances in Experimental Embryology," by Prof. E. W. McBride, at the Imperial College, Royal College of Science, Exhibition Road, S.W.7, at 5 p.m. on June 7, 8, and 9. A lecture on "Permeability in Physiology and Pathology," by Prof. H. J. Hamburger, at the rooms of the Royal Society of Medicine, 1 Wimpole Street, W.1, at 5 p.m. on June 8 (this lecture is the last of a series of six arranged under the scheme for the exchange of lecturers in medicine between England and Holland). A course of four lectures on "The Therapeutic Use of Digitalis," by Prof. F. R. Fraser, in the surgical lecture theatre, St. Bartholomew's Hospital Medical School, West Smithfield, E.C.1, at 5 p.m. on June 13, 15, 17, and 20.

MR. H. J. DAVIS has been appointed to a lectureship in mathematics in the Bradford Technical College. He is at present senior lecturer in mathematics in the University College, Southampton, and has specialised on the theory of statistics.

THE Secretary of State for India in Council has made the following appointments to the Indian Educational Service:—To be professor of physics in Presidency College, Madras, Dr. Shankar Rao Ullal Savoor; to be professor of biology in the University of Rangoon, Dr. J. Brontë Gatenby.

PROF. E. G. COKER, professor of civil and mechanical engineering, University College, London, has accepted invitations from the Universities of Ghent and Louvain to lecture there next week on "Recent Researches in Photo-Elasticity," and also one from the Société Belge des Ingénieurs et des Industriels to lecture in Brussels on "The Applications of Photo-Elasticity to Engineering."

THE Anglo-Swedish Society (10 Staple Inn, W.C.1) has awarded two scholarships of 50*l*. each to be spent on travelling in Sweden: one to Miss Dorothy Cridland, to enable her to study the industrial economy of the country; the other to Mr. G. R. Carline, to aid his study of the open-air and folk museums of Sweden and their influence on national life. Similar scholarships will be awarded in the spring of each year.

THE Ramsay Memorial Trustees will at the end of June consider applications for two Ramsay Memorial fellowships for chemical research. One of the fellowships will be limited to candidates educated in Glasgow. The value of the fellowships will be 250*l*. per annum, to which may be added a grant for expenses not exceeding 50*l*. per annum. Full particulars as to the conditions of the award are obtainable from Dr. Walter W. Seton, secretary, Ramsay Memorial Fellowships Trust, University College, London, W.C.1.

THE Science Masters' Association, in response to an invitation to co-operate with the staff of the Rothamsted Experimental Station, Harpenden, has issued to its members, representing upwards of three hundred schools, a circular outlining the types of research work in which it is believed that school science and natural history clubs can best give the assistance solicited by the Rothamsted experts. The lines suggested are:—(1) The weed-flora of arable land, its relation to the type of soil, to the geological formation, to the system of manuring, to the crop rotation, and so on; (2) the physical properties (texture, pore-space, water-content, etc.) of the soil; and (3) the carbonate-content and the nitrogen-content of the soil. These have the merit of presenting a certain degree of finality that is within the reach of a boy in the course of one or two school terms. The weed-flora problems should appeal to the field club, while the other two should be attractive to boys whose bent is chemical and physical rather than biological. It is a step entirely in the right direction thus to link up the work of those still *in statu pupillari* with that of experts seriously engaged in research. The moment is very opportune for bringing home to the minds of boys that their amateur efforts in research may speedily be of real benefit to mankind and add to the sum of knowledge relating to the complex problems of plant-life. The work is of high educational value, and also of very practical utility; it deserves warm encouragement for both educational and utilitarian reasons. It is not beyond hope that industries other than agriculture may ere long enlist the services of schools in their several research problems.

Calendar of Scientific Pioneers.

May 27, 1914. Sir Joseph Wilson Swan died.—A partner in a firm of chemical manufacturers at Newcastle, Swan became famous by his invention of the carbon process in photography and by his pioneering work on the incandescent electric lamp. His first carbon filament lamp was shown at Newcastle in 1879. He received many honours, and in 1898–99 was president of the Institution of Electrical Engineers.

May 28, 1893. Charles Pritchard died.—Graduating as a Wrangler in 1830, Pritchard from 1834 to 1862 was headmaster of a successful grammar school at Clapham. In 1870, at the age of sixty-three, he became Savilian professor of astronomy at Oxford. He was a pioneer in the photographic measurement of stellar parallax, invented the wedge photometer, and in 1885 published his "Uranometria Nova Oxoniensis."

May 28, 1906. Rudolf Knietsch died.—A native of Silesia, Knietsch in 1884 became a director of the Badische Anilin- & Soda-Fabrik at Mannheim, where he played an important part in the manufacture of artificial indigo and in that of sulphuric acid by the contact process.

May 29, 1829. Sir Humphry Davy died.—Already famous for his discovery of nitrous oxide, in 1801 at the age of twenty-three, and at a salary of 100*l.* a year, Davy became the first professor of chemistry at the Royal Institution. His great discoveries of sodium and potassium were made there in 1807. In 1815 he invented his miners' safety-lamp. Knighted in 1818, he was president of the Royal Society from 1820 to 1827. His death occurred at Geneva.

May 29, 1896. Gabriel Auguste Daubrée died.—Trained in Paris as a mining engineer, Daubrée became professor of geology in the Musée d'Histoire Naturelle and Director of the School of Mines. He carried out an important series of experimental researches in geology.

May 29, 1897. Julius von Sachs died.—Professor of botany at Würzburg from 1868, Sachs contributed to all branches of botany, and especially to plant physiology. His well-known text-book was published in 1865 and his "History of Botany" ten years later.

May 29, 1898. Sir Lyon Playfair, first Baron Playfair of St. Andrews, died.—Chemist to the Geological Survey and the School of Mines, Playfair from 1856 to 1869 was professor of chemistry at Edinburgh. He entered Parliament, held public office, and did much to further the study and application of science. He was knighted in 1883 and raised to the peerage in 1892.

May 31, 1867. Théophile Jules Pelouze died.—Joint author with Frémy of an important treatise on chemistry, Pelouze made researches in organic chemistry, lectured at the Collège de France and the Ecole Polytechnique, and became President of the Mint.

June 1, 1812. Richard Kirwan died.—Of independent means and possessing many accomplishments, Kirwan was the correspondent of many scientific men, and in 1799 became president of the Royal Irish Academy. His "Elements of Mineralogy" (1784) was the first systematic treatise on that subject in English, and his essay on Phlogiston (1787) was one of the last attempts to defend Stahl's theories. Kirwan acknowledged his conversion to Lavoisier's views four years later.

June 1, 1903. J. Peter Lesley died.—Born at Philadelphia and educated for the ministry, Lesley assisted in geological work and ultimately became professor of geology in the University of Pennsylvania, and from 1874 to 1893 directed the Geological Survey of that State.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, May 12.—Prof. C. S. Sherrington, president, in the chair.—G. W. **Walker**: The problem of finite focal depth revealed by seismometers. Observations of the emergence angle of P waves at Pulkovo suggest that the depth of focus is of order one-fifth of the earth's radius. Important modifications are necessary in the interpretation of seismograms and in the attempt to determine how speed of propagation depends on depth. A test of the accuracy of the Pulkovo values can be made by a scrutiny of seismograms for distances >11,000 kilometres. Corresponding measures of the angle of emergence of S waves by means of three component seismometers are required.—E. A. **Griffiths**: A liquid oxygen vaporiser. The liquid oxygen is contained in a metal vacuum vessel. The emission of gas is governed by bringing a flexible portion of the outer wall into contact with the inner; the degree of contact determines the rate of transmission of heat. Any desired rate of gas evolution can be obtained up to 10 litres per minute, and the delivery remains constant.—Dorothy M. **Palmer** and W. G. **Palmer**: Some experiments on the catalytic reduction of ethylene to ethane. The hydrogenation of ethylene in the presence of nickel has been quantitatively examined. The mixture of ethylene and hydrogen was brought into contact with nickel in motion in an electrically heated tube. The rate of hydrogenation was measured by the rate at which a mixture of ethylene and hydrogen in equal proportions by volume had to be passed into the tube to maintain the gas therein at constant pressure. The effects of varying conditions were studied. The curves showing rate of reaction against time display "induction" periods during which no hydrogenation took place, varying in duration from a few seconds to many hours, according to the conditions of the experiment. Then the rate of reaction increases rapidly to a sharp maximum, and decreases less rapidly to a lower value, which decreases slowly. A theory is advanced to account for these effects.—W. G. **Palmer**: The catalytic activity of copper. Part ii. The activity of copper when prepared from oxide by reduction with carbon monoxide and methyl alcohol vapour is discussed. Constant-boiling mixtures of several alcohols with water were used as reactants. Water acts as a positive, and hydrogen as a negative, auxiliary catalyst when adsorbed on the copper. The activity-temperature curves for a catalyst prepared by carbon monoxide obey a simple exponential law. Between 270° and 280° C. the activity curves generally undergo a sudden change of direction corresponding to a great reduction of the temperature coefficient. This is attributed to the diminution in the thickness of the adsorbed alcohol layer to at most two molecular diameters. The activity of the catalyst does not increase continuously, as the temperature of its preparation from oxide is lowered.—Prof. C. F. **Jenkin** and D. N. **Shorthose**: The total heat of liquid carbonic acid. The total heat of carbonic acid between temperatures of +10° C. and +100° C. and between pressures of 900 lb. and 1800 lb. per square inch was measured. The values hitherto accepted, based on the assumption that the specific heat at constant volume does not change over this range, require slight correction.—Dr. A. O. **Rankine**: The viscosity and molecular dimensions of gaseous cyanogen. The viscosity of gaseous cyanogen has been measured at 15° C. and 100° C., the values obtained being, respectively, $0{\cdot}986 \times 10^{-4}$ and $1{\cdot}264 \times 10^{-4}$ C.G.S. units. Assuming Sutherland's law of temperature variation, the data have been used

to calculate Sutherland's constant (C. = 280) and the viscosity at 0° C. (η_0—0·935 × 10⁻⁴ C.G.S. units). The mean collision area of the molecule of cyanogen deduced, — 1·31 × 10⁻¹⁵ cm.², proves to be practically the same as that of a bromine molecule, 1·28 × 10⁻¹⁵ cm.² This is consistent with the evidence from crystal examination, for the molecular volumes of KBr and KCN are nearly equal. If X-ray crystal examination should prove that KCN and KBr are strictly isomorphous, the results here obtained are consistent with the Lewis-Langmuir view that the cyanogen molecule has a size and shape nearly the same as those of two nitrogen molecules linked together by sharing one pair of outer electrons.

Linnean Society, May 5.—Dr. A. Smith Woodward, president, in the chair.—Prof. A. **Dendy**: Hexactinellid sponges. The origin on certain elongated siliceous spicules of discs at regular intervals corresponds almost exactly with the nodal points of a vibrating body as determined by Prof. J. W. Nicholson.—Six papers dealing with various groups of insects collected by the Percy Sladen Trust Expedition:—C. G. **Lamb**: Diptera (iii.). A report chiefly on the Dolichopodidæ, a large family of small- or middle-sized flies, usually of beautiful metallic green or golden colours. The general affinities of the Seychelles forms are discussed. Most of them belong to a subfamily largely represented in the tropics, the Chrysosomatinæ or Psilopinæ; some of these flies, with dazzlingly brilliant golden-green bodies, settle in bright sunlight on broad leaves; another group of smaller and much duller-coloured species is almost entirely confined to the damp, shady mountain forests. A new genus, characterised by the males having at the base of the abdomen a pair of remarkable hollow spherical bulbs, with a round opening at the top through which can be seen a rod rising from the bottom of the bulb, is described. The bases of the wings are also highly modified. The Asilidæ and the Syrphidæ are also discussed.—H. **Gebien**: The Tenebrionidæ. A large family, mostly of large- or middle-sized beetles. The known Tenebrionid fauna of the island is increased from twelve to forty-one species; of these twenty-one are probably endemic, and eleven belong to endemic genera. The endemic genera are isolated and specialised forms. The idea previously advanced by Kolbe, that certain of these peculiar forms indicate relationships between the fauna of the Seychelles and those of New Zealand and South America, is not upheld, for the endemic species which do not belong to endemic genera present Oriental affinities. There is a much less pronounced Madagascan element, while the African element is represented only by a single widespread form.—Mr. **Schenkling**: The Cleridæ. A strong affinity exists with the fauna of Madagascar, four out of the six Seychelles species being new and having strongly Madagascan affinities, while the two remaining species are cosmopolitan. One of the new Seychelles forms has a superficial resemblance to an Anthribid beetle from the same islands. Both belong to new genera, Cleranthribus and Anthriboclerus. There are no data to show relationship between them.—Dr. M. **Bernhauer**: The Staphylinid beetles. The known Staphylinid fauna of the Seychelles is increased from twenty-eight to eighty-one species. The report also includes one species from the Chagos Islands and two from Aldabra. The conclusions of earlier writers were that the affinities of the Seychelles Staphylinidæ were, on the whole, Oriental, but that a smaller Madagascan element and a very small African element were included. These conclusions are in the main upheld, but generalisations must be accepted with reserve, for the smaller forms are still practically unknown in surrounding continents, and it is not known which species have reached the islands by natural means and which through human agency. A summary of observations on habits is given.—Dr. H. **Scott**: Clavicorn and other beetles. A great deal of fine work on the external anatomy was done in describing these forms. Numerous interesting points in the structure of tarsi, antennæ, mouth-parts, etc., and some remarkable secondary sexual characters, came to light. The geographical distribution is shown by a tabulated comparison of the numbers of representatives of these families in the Seychelles with the faunas of the Hawaian and of the Atlantic islands. The Seychelles have a great number of families and genera, usually represented by a few clearly separable species. The Hawaian islands have several families altogether wanting, while in other groups they possess great "endemic complexes."—Florence E. **Jarvis**: The Hydroids of the western Indian Ocean. An account of the collections obtained during the voyage of H.M.S. *Sealark* at varying depths to 130 fathoms and of some shallow coastal collections made by Mr. C. Crossland off East Africa. There are eleven Gymnoblastea and seventy-four Calyptoblastea. The number of new species is relatively small, the influence of depth and currents being emphasised as having a marked effect on the habit of colonies. All the larger families are represented, the group being practically cosmopolitan; there are no new genera, but the species comprise a number of new Plumularians.—Dr. C. I. **van der Horst**: Madreporaria, Agariciidæ. Twenty-nine species are recorded belonging to the genera Agaricia, Pavona, Podabacia, Leptoseris, Siderastrea, Coscinaræa, Psammocora, and Pachyseris. The type-specimens of previous authors have generally been consulted. Three species are described as new. The examination of the collection has resulted in many species, previously described as different, being shown to be connected by transitional forms.—E. R. **Speyer**: Insects in relation to the reproduction of coniferous trees. The destruction of the cones of *Pseudotsuga Douglasii*, Carr., *Pinus ponderosa*, Dougl., and *P. echinata*, Mill., by various insects was discussed.

Zoological Society, May 10.—Dr. A. Smith Woodward, vice-president, in the chair.—R. I. **Pocock**: The auditory bulla and other cranial characters in the Mustelidæ (martens, badgers, etc.).—G. S. **Thapar**: The venous system of the lizard, *Varanus bengalensis*, Daud.

Royal Meteorological Society, May 18.—Mr. R. H. Hooker, president, in the chair.—J. E. **Clark** and H. B. **Adames**: Report on the phenology of the British Isles, December, 1919, to November, 1920. The abnormal mildness and wetness up to mid-April ruined fruit-tree crops through too early blooming. Field crops suffered through drought in May and June and the cold sunlessness of July and August, with excessive wet in the former month. After June, in England, the accumulated temperature above 42° (that at which wheat will grow) fell more and more behind the mean until October, which, by its warmth, sunshine, and dryness, gave a wonderful seeding time in earlier districts and helped to save crops in the later. In 1920 the four spring flowers were, in England and Wales, 13½ days early (February 27); 10 days (March 3) for the whole of the British Isles. The latter date for 1919 was March 15. The succeeding flowers became less and less early, until the two of July were just average. From 1921 on observers are asked to include the Devil's-bit scabious in order to

extend the records into August. The mean date of all is 8·2 days earlier, or the earliest in the thirty years except 1893 (14 days). The latest were 1891 (9½ days late) and 1917 (7½ days). Two charts show by isohels, isotherms, and isophenes the relation between lines of equal sunshine, equal temperature, and equal appearance of flowers. The correspondence is closest between the last two. Thus the average flowering date ranges from April 19, in the south-west, near the isotherm of 50°, to May 31 on the isophene lying between isotherms 45° and 44°, 7° further north, which represents a rate of change of 6 days for each degree. In continental districts, European and North American, the rate is nearer 4 days. Bird migrations and appearances of insects confirm the plant records. The former were 3½ days earlier than the mean of the seven years available.—Dr. E. J. **Salisbury**: Phenology and habitat, with special reference to woodlands. The observations of Klebs and Lakon have shown the importance of conditions of nutrition in determining periodic phenomena. Raun Kaier has, moreover, shown that earliness or lateness in foliar development is an hereditary character. Probably no less important is the influence of habitat. The flowering period of chalk-down plants is, on the whole, early, whilst that of aquatics is late, but the close relation between phenology and habitat is best illustrated by woodland plants. Here we find there is a definite sequence from below upwards. Taken as a whole, woodland species develop earlier than non-woodland, but this is especially true of the shade flora. The average date for the inception of foliar development of woodland herbs, which lose their leaves during the winter, is February 19. Many, however, retain all or part of their foliage throughout the "light-phase." The leafage of the shrubs begins about a month later (average date March 19), and that of the trees towards the end of April (average, April 21). This upward sequence and its early inception are clearly correlated with the diminished light (7 to 1 per cent. of that in the open) in the interior of the wood from the end of May to the beginning of November. Such facts emphasise the importance of choosing species for phenological observation belonging to similar habitats and possessing aerial and underground organs of a similar nature. Further leafage appears to be more susceptible to meteorological changes than the flowering period, which is the usual subject of meteorological observation.

PARIS.

Academy of Sciences, May 2.—M. Georges Lemoine in the chair.—J. **Boussinesq**: Rectification and completion of a note of April 18 on the flattening of a rotating liquid drop.—T. **Bonnesen**: An improvement of the isoperimetric inequality of the circle and the demonstration of an inequality of Minkowski.—M. **Alayrac**: The movement of the centre of gravity of a solid symmetrical with respect to a vertical plane displacing itself in a resisting medium.—H. **Godard**: Observations of Winnecke's comet (1921*b*) made at the Bordeaux Observatory with the 38-cm. equatorial. Apparent positions and positions of comparison stars given for April 26, 28, and 29. The comet was of the 12th magnitude.—J. **Malassez**: The use of the lamp with three electrodes for the measurement of ionisation currents.—F. **Guéry**: Some consequences of the Lorentz contraction from the point of view of cohesion, of gravitation, and of electromagnetism.—G. **Contremoulins**: The protection of third parties against X-rays. The range of the radiations emitted by a Coolidge tube is considerable, and the effects have been traced up to a distance of 80 metres.—C. **Raveau**: Saturated solutions of two or more substances. The application of Le Chatelier's principle.—E. **Darmois**: The specific dispersion of hydrocarbons.—A. **Damiens**: Tellurium tetraiodide. An account of the preparation, purification, and physical and chemical properties of the iodide TeI_4. It is a well-defined compound, and will serve as a raw material for the preparation of numerous derivatives of tellurium.—A. **Mailhe**: The catalytic hydrogenation of the phenylhydrazones. The phenylhydrazones of aldehydes carried over nickel at 180° C. by a current of hydrogen split up into aniline and nitriles; the reduction to fatty amine and aniline is secondary. Phenylhydrazones of ketones behave differently, the reduction with production of fatty amine being the main reaction.—P. **Palacios**: Observations on a note on the tectonic of the western Pyrenees. Remarks on a recent communication by P. Stuart-Menteath.—F. **Kerforne**: The age of the oldest strata of the Armorican massif.—P. **Bonnet**: Liassic volcanic eruptions and their relations with the distribution of the facies in the Caucasian geosynclinals.—M. **Dort**: The variations of the solar radiation during the eclipse of the sun of April 8, 1921, at Bagnères-de-Bigorre, observatory station on the Pic du Midi. Observations were made with an actinometer of the Violle type and reduced to 15-minute intervals between 8 and 10.15 a.m. The figures are compared with the mean of corresponding measurements made on April 7 and 11.—M. **Molliard**: The influence of sodium chloride on the development of *Sterigmatocystis nigra*. The addition of salt to the culture medium above a certain concentration reduces the velocity of the chemical reactions of the mould; it also indirectly causes sterility of the mycelium owing to the accumulation of nitric acid.—G. **Astre**: Contribution to the study of the distribution of the biological zones on the Mediterranean dunes of the Gulf of Lyons.—M. **Manquat**: The phototropism of *Leucoma phaeorrhoea*. The author's observations on the action of light on the young caterpillars of *L. phaeorrhoea* do not confirm the conclusions of Loeb.—E. **Couvreur** and X. **Chahovitch**: Microbial infections in the invertebrates. Criticisms of a recent paper by M. Paillot on the same subject.—F. **Vlès** and J. **Dragoiu**: The osmotic pressure of arrest of cell division. The cells studied were those of the eggs of the sea-urchin, and these were grown in sea-water containing sugar in solution. With osmotic pressures between 25 atmospheres (sea-water) and 30 atmospheres the effects were negligible. Between 30 and 50 atmospheres the percentage of eggs achieving division fell rapidly to zero. Ten per cent. of the eggs had their division stopped at 33 atmospheres and 90 per cent. at 39 atmospheres.—M. **Bridel**: The action of emulsin on galactose in solution in propyl alcohol of different concentrations.—E. **Kayser**: The influence of uranium salts on nitrogen fixation. A study of the effect on addition of uranium salts on the growth of *Azobacter agile* in glucose and mannite culture media.—R. **Anthony** and C. **Champy**: The reptilian form of the spermatozoid of *Manis javanica* and its signification.—R. **Hovasse**: The parthenogenetic activation of the eggs of *Rana temporaria* in hypotonic and hypertonic media.—C. **Lebailly**: Bovine aphthous fever is not transmissible to man; human aphthous stomatitis is not transmissible to cattle.—M. **Mirande**: Lathyrism, or the intoxication produced by vetch-seeds. The seeds of *Lathyrus sativus* and *L. cicera* have been proved to be poisonous to horses. The ground-up seeds, moistened with water, undergo a spontaneous fermentation, and sulphuretted hydrogen is evolved. The poisonous action of the seeds is most probably due to the evolution of this gas in the stomach.

Books Received.

Priestley in America, 1794–1804. By Edgar F. Smith. Pp. v+173. (Philadelphia: P. Blakiston's Son and Co.) 1.50 dollars net.

How to Teach Agriculture: A Book of Methods in this Subject. By Prof. Ashley V. Storm and Dr. Kary C. Davis. Pp. vii+434. (London: J. B. Lippincott Co.) 12*s*. 6*d*. net.

Diary of Societies.

THURSDAY, MAY 26.

INSTITUTION OF GAS ENGINEERS (at Institution of Civil Engineers), at 10 a.m.

ROYAL HORTICULTURAL SOCIETY (at Chelsea), at 3.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—E. Law: The Architecture and Art of Hampton Court Palace. II. In Stuart and Later Times.

ROYAL SOCIETY, at 4.30.—Sir Alfred Ewing: The Atomic Process in Ferro-magnetic Induction.—C. D. Ellis: The Magnetic Spectrum of the β-rays excited by the γ-rays.—S. Datta: The Spectra of the Alkaline Earth Fluorides and their Relation to Each Other.—Dr. W. L. Balls: A Simple Apparatus for Approximate Harmonic Analysis and for Periodicity Measurements.—Dr. G. R. Goldsbrough: The Influence of Satellites upon the Form of Saturn's Ring.—Dr. H. Jeffreys: Certain Geological Effects of the Cooling of the Earth.—T. Kikuchi: The Moving Striations in a Neon Tube (title only).

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital, Paddington), at 4.30.—Dr. J. A. Murray: Aims and Progress of the Experimental Study of Cancer.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place), at 6.—A. Johnsen and K. Rahbek: A Physical Phenomenon and its Application to Telegraphy, Telephony, etc.

CONCRETE INSTITUTE (Annual General Meeting), at 7.30.—L. S. White: Land Subsidence and its Effects on Concrete and other Structures.

ROYAL SOCIETY OF MEDICINE (Urology Section) (Annual General Meeting), at 8.30.—V. Z. Cope: Genito-urinary Symptoms in Acute Appendicitis.

FRIDAY, MAY 27.

ROYAL SOCIETY OF ARTS (Indian and Colonial Sections), at 4.30.—Sir Charles H. Bedford: Industrial (including Power) Alcohol.

PHYSICAL SOCIETY OF LONDON (at University College), at 5.—The General Electric Co. (communicated by C. C. Paterson): A Method for the Micro-analysis of Gases by the Use of the Pirani Pressure Gauge.—H. Pealing: The Reflection of the K-ray Spectrum of Palladium from Fluorspar.—Sir W. H. Bragg: The Intensity of X-ray Reflection by Diamond.—Exhibits of Crystal Models, and of Photographs by the Duc de Broglie of β-ray Spectra produced by X-rays.

ROYAL BOTANIC SOCIETY OF LONDON, at 5.15.—E. Law: Shakespeare's Garden, as it was, is now, and is to be.

ROYAL SOCIETY OF MEDICINE (Study of Disease in Children Section)

(Annual General Meeting), at 5.30.—Dr. H. Thursfield: The Diagnosis of a Case of Renal Calculus in a Child.

INSTITUTION OF MECHANICAL ENGINEERS, at 6.—J. G. Graves: The World's Money System.

JUNIOR INSTITUTION OF ENGINEERS, at 8.—S. A. Stigant: Notes on Electrical Transformer Breakdowns.

ROYAL SOCIETY OF MEDICINE (Epidemiology and State Medicine Section) (Annual General Meeting), at 8.30.—Dr. R. J. Reece: Some Observations on the Occurrence of Cow-pox and Human Cases in Connection Therewith.—Dr. F. R. Blaxall: Some Notes on the Preparation of Vaccine Lymph at the Government Lymph Laboratory.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—A. Mallock: Elasticity.

SATURDAY, MAY 28.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—F. Legge: Gnosticism and the Science of Religions. II.

MONDAY, MAY 30.

SURVEYORS' INSTITUTION (Annual Meeting), at 5.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall) (Anniversary Meeting), at 5.30.

ROYAL SOCIETY OF ARTS, at 8.—Sir Kenneth Weldon Goadby: Immunity and Industrial Disease.

NATIONAL UNION OF SCIENTIFIC WORKERS (in Botanical Theatre, University College), at 8.—Chairman: Viscount Haldane.—Prof. L. Bairstow: The Administration of Scientific Work (followed by a Discussion).

TUESDAY, MAY 31.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir James Frazer: Roman Life: Time of Pliny the Younger.

FARADAY SOCIETY (at Chemical Society), 4.30-6.30 and 8-10.30.—Discussion on Physico-chemical Problems Relating to the Soil.—Dr. E. J. Russell: A General Survey of the Subject.—B. A. Keen: The System Soil—Soil Moisture.—Prof. D. R. Hoagland: The Soil Solution in Relation to the Plant.—Dr. C. A. Shull: Activity and Imbibition in Relation to Soil Moisture.—H. J. Page: The Part Played by Organic Matter in the Soil System.—Prof. Sven Oden: The Application of Physico-chemical Methods to the Study of Humus.—Dr. E. J. Salisbury: The Vertical Distribution of Soil Acidity in Natural Soils and its Relation to the Organic Constituents.—E. A. Fisher: The Phenomena of Absorption in Soils: a Critical Discussion of the Hypotheses Put Forward.—E. M. Crowther: Soil Acidity in its Physico-chemical Aspects.—C. G. T. Morison: Pan Formation.—Prof. Sven Oden: The Clays as Disperse Systems.—N. M. Comber: The Mechanism of Flocculation in Soils.—Dr. J. W. Mellor: Plasticity of Clay.—G. W. Robinson: The Physical Properties of the Soil in Relation to Survey Work.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place), 5.—Annual General Meeting. 5.45.—Special General Meeting. At 6.30.—Ordinary Meeting. Dr. F. B. Jewett: Research Work in the United States.

ROYAL SOCIETY OF MEDICINE, at 5.—General Meeting of Fellows.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—Dr. C. T. Holland: The Snow and Ice Scenery of Switzerland.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.

ILLUMINATING ENGINEERING SOCIETY (Annual Meeting) (at Royal Society of Arts), at 8.15.—J. S. Dow: The Use of Artificial Light as an Aid to Various Games and Sports.

WEDNESDAY, JUNE 1.

ROYAL SOCIETY OF MEDICINE (Surgery Section), at 5.30.—C. A. Pannett: The Treatment of the Imperfectly Descended Testicle.—Dr. A. Goodman Levy: Cardiac Massage.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS (at Chemical Society), at 8.—F. F. Beach, T. E. Needs, and E. Russell: The Composition of Egg Powder.—N. Evers: The Colorimetric Method of Determining Hydrogen-ion Concentration: Some Uses in the Analytical Laboratory.—F. R. Dodd: The Estimation of Woody Fibre in Cattle Foods.

ENTOMOLOGICAL SOCIETY OF LONDON, at 8.

THURSDAY, JUNE 2.

ROYAL SOCIETY OF MEDICINE (Laryngology Section) (Summer Meeting), 2.30 to 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Alexander C. Mackenzie: Beethoven.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital), at 4.30.—Prof. G. Dreyer: A New Departure in the Serum Diagnosis of Syphilis.

ROYAL SOCIETY, at 4.30.—Dr. T. M. Lowry and Dr. C. P. Austin: Optical Rotatory Dispersion (The Bakerian Lecture).

LINNEAN SOCIETY, at 5.—Prof. Garstang and Others: Discussion on Biogenetic Law (Recapitulation).

CHEMICAL SOCIETY, at 8.—H. King: Derivatives of Sulphur in Commercial Salvarsan. Part I.—S. Glasstone: Physical Chemistry of the Oxides of Lead. Part I. The Solubility of Lead Monoxide.—M. O. Forster and W. B. Saville: Studies in the Camphane Series. Part XXXIX. *p*-Aminophenylaminocamphor (Camphoryl-*p*-phenylenediamine).—K. Stratton and J. R. Partington: Latent Heats of Fusion. Part I. Benzophenone, Phenol, and Sulphur.—G. T. Morgan and H. D. K. Drew: Researches on Residual Affinity and Co-ordination. Part V. Gallium Acetylacetone and its Analogues.—J. C. Thomlinson: Analysis of Cresol Disinfectants.—G. T. Morgan and D. Webster: Diazo-derivatives of 4-amino-phenyl-4′-methylbenz-2′:7′-thiazole (Dehydrothio-*p*-toluidine).—A. K. Macbeth and D. D. Pratt: The Labile Nature of the Halogen Atoms in Substituted Nitromethanes.—K. G. Naik: The Formation and Properties of Dithioketones $(R_2C:S:S)$ and Dithioethers $(RS:S)$. Part II.—K. G. Naik: The Formation and Properties of Dithioketones $(R_2C:S:S)$ and Dithioethers $(R_2S:S)$. Part III. Interaction of Sulphur Monochloride with Organic Compounds containing the grouping

$$-CO-CH_2-CO-CH_2-CO-.$$

K. G. Naik: The Formation and Properties of Dithioketones $(R_2C:S:S)$ and Dithioethers $(R_2S:S)$. Part IV. Interaction of Sulphur Monochloride with Organic Compounds containing $-CO-CH_2-CO-$ grouping, forming the Part of a Closed Ring.—K. G. Naik: The Formation and Properties of Dithioketones $(R_2C:S:S)$ and Dithioethers $(R_2S:S)$. Part V. Nitration of Dithioketones and Dithioethers.—K. G. Naik: Interaction of Sulphur Monochloride with Organic Acid Amides.—S. J. Lewis and F. M. Wood: A New Adjustable Thermostat for all Temperatures between 0° and 100°.—H. Burton and J. Kenner: The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part III. The Partial Reduction of the Dinitrotoluenes by Stannous Chloride and Hydrochloric Acid.—J. Kenner and E. Witham: The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part IV. The Condensation of Ethyl 3- and 5-nitro-*o*-Chlorobenzoates with Hydrazines.

FRIDAY, JUNE 3.

ROYAL SOCIETY OF MEDICINE (Laryngology Section) (Summer Meeting), 10 to 1.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botanical Lecture Theatre, Imperial College of Science), at 2.30.—F. L. Engledow: Methods of Increasing Yield in Crop Plants.—C. B. Saunders: Some Problems of Seed Testing.—W. Brown: The Physiology of Infection.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—M. Adams: Eyes in Portraiture.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. L. Huxley: Chronicles of the Cornhill.

SATURDAY, JUNE 4.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. R. S. Rait: Scotland and France.

The Metric System and World Trade.

A SHORT time ago (March 29) Dr. C. E. Guillaume contributed to the Paris Academy of Sciences a paper on the obligatory adoption of the metric system in Japan. The recent Japanese law making the metric system compulsory after a fixed period will no doubt have considerable effect towards rendering the system familiar in trade in the Far East, where its use is already facultative in some countries. Before arriving at this decision the Japanese Government dispatched a Commission of Inquiry to the principal trading centres of the world, so that the present law represents the outcome of prolonged and mature judgment, and as such supplies very satisfactory evidence in support of the international claims of the metric system. The values of the old units of Japan have for many years been defined in terms of the metre and the kilogram, and, owing to this fact and to the issue of regulations on the subject, the trading community has gradually become accustomed to metric weights and measures. Dr. Guillaume expects that in a few years the only weights and measures permissible in eastern Asia will be those of the metric system. The enormous strides made by this system in the Far East cannot be without effect in the United States, where in the past one of the principal arguments against it was that British weights and measures were tacitly recognised in China, Japan, and Siam. It appears probable, therefore, that before long advocates of the metric system will be able to turn this line of reasoning against their opponents.

By its recent decision Japan has once more shown its readiness to change its customs in order to adapt itself to changing needs. Its statesmen have recognised that the metric system is the only system of service for international trade, and have, therefore, decided that their country shall not be handicapped by traditional use and human inertia from adopting new standards of measurement. We have no patience with any other policy. Whether a principle is sound or not may be discussed, and whether its adoption is expedient or not may also be a matter of opinion; but to suggest that a particular policy should not be followed merely because there are many difficulties in the way is to manifest a state of mind which we fail to understand. The first thing to decide in individual or national life is whether an action is right; and once having arrived at an affirmative conclusion, difficulties are nothing but obstacles to be surmounted boldly or swept aside ruthlessly from the path of progress.

This we conceive to be the true scientific spirit, and by the use of it Japan has won the high position which she now occupies among the nations of the world. We must confess, however, that in the matter of the adoption of the metric system there are few signs that like action will readily be taken in our own country. It is perhaps not surprising that Lord Balfour of Burleigh's Committee on Commercial and Industrial Policy after the War should have reported that it was not desirable to make a compulsory change in our system of weights and measures; but we expected something different from a committee appointed by the Conjoint Board of Scientific Societies. The report of this committee was dealt with in our issue of October 7 last, p. 169, and the only satisfactory thing about it from our point of view is that the Conjoint Board declined to adopt the report, which was, therefore, published on the authority of the committee alone.

In justice to the committee it must be said that the inquiry with which it was entrusted was solely that of the compulsory adoption or otherwise of the metric system in the United Kingdom, and not the advantages or disadvantages of the system in comparison with the British system of weights and measures, or its scientific aspects in general. Some of these subjects were, however, discussed—not altogether impartially—by the committee in its report; and the conclusion

reached was "that the British system of units of weights and measures be retained in general use in the United Kingdom." Interesting suggestions were made as to the decimalisation of our system and the abolition of several unnecessary units; but even if this were accomplished the result would still be that British manufacturers would have to continue to employ two systems—one for home trade, the other for trade with the increasing number of countries overseas in which the metric system is commonly used.

Neither Lord Balfour's Committee nor that of the Conjoint Board gave adequate attention to the value of official encouragement as a *via media* between legal permission and legal compulsion. The Act of 1897 made the use of the metric system permissive, and official adoption of the system now would pave the way to legal compulsion at a later date.

The many reports of our Consuls and representatives abroad have shown in the most convincing way that the practice of those British manufacturers who use only British weights and measures in their catalogues and price lists intended for other countries has a prejudicial effect on the extension of our foreign trade, particularly in countries where the metric system is used exclusively. In the textile trades British measures are no doubt widely recognised; but there is not the slightest reason for hope that their usage can be made international by common consent. The only possible international system is the metric system, and as a nation we cannot afford permanently to remain outside it. When the metric carat was legalised for use in trade in 1914, its adoption by dealers in diamonds and precious stones was practically complete in a few weeks, though they were previously opposed to the change. The weights and measures now given in the British Pharmacopœia are all in the metric system, and Imperial standards are entirely omitted. The dual system formerly used was found to be a constant source of trouble, and in 1914 it was abandoned in favour of the metric system alone. In mining statistics the metric ton is now a common standard, and in many engineering and ordnance machines and structures metric measures are now used almost as frequently as British. It cannot be said that our system of weights and measures is extending to other nations in the same way. Nothing that we could do would make the system international, so that what we have to do is to choose between a system which has custom alone to commend it, and must be limited in its use and one which extends over the whole world and becomes more important industrially and commercially every year.

The adoption of the metric system by the United States and the United Kingdom is, indeed, inevitable, and adherence to the Imperial system is an obstacle to world commerce. We shall have to abandon the system sooner or later, and it would not be so difficult to adjust ourselves to the new standards now as it is to adapt ourselves to other conditions of reconstruction brought about by the war. The Colonies have frequently expressed their desire to adopt the system whenever the United Kingdom does so; all our European Allies, and practically half the population of the world, use it, and we cannot avoid doing so eventually. The only two important countries now outside the system are the United States and the United Kingdom, and when either of these enters it the other must follow.

During the war we, and the United States also, were forced to use metric measures in order to secure effective co-ordination between us and our Allies in military maps, range finding, firing data, and ordnance generally, and in the uniform standardisation of motors, aeroplane parts, and other machines and accessories. The result is that millions of men are now familiar with metric units, and would experience little difficulty in adjusting themselves to the change which the introduction of the metric system would involve. Every pupil in every secondary school in this country is made acquainted with the system, and in scientific work its use is universal. "The present chaos of English weights and measures," reported Sir J. J. Thomson's Committee on the position of natural science in the educational system of Great Britain, "causes waste of time and confusion of thought, and these are strong educational reasons for the adoption of the metric system."

The truth is that we have not a uniform system of weights and measures, but a medley of units and standards which differ in different industries and often vary in a single industry. In agriculture a bushel of wheat is defined in official statistics as having a weight of 62 lb.; by the Corn Returns Act it weighs 60 lb., and by the Grain Prices Order 63 lb. Bushels of barley and oats show like variations in weight both officially and according to frequent practice. To secure

uniformity in the weights and measures used in the sale of corn and other crops, the Corn Sales Bill is now being considered by a Committee of the House of Commons; but as the standard proposed is one of 112 lb., while the whole of the futures market is based on the decimal system, the Bill can be nothing more than a makeshift measure. In the textile industries, from which comes the chief opposition to the use of metric measures, the standards of measurement vary greatly in different centres, and there is no common relationship between them. British and American measures with the same denomination, such as the pound, yard, gallon, and bushel, also differ in quantity in the two countries. The advantages of a uniform system—a common language—from the point of view of world service are obvious, and the jealous attitude of conservative corporations towards it represents, not the spirit of progress, but rather that of obscurantism.

The fact that local and trade usage sanctions such a variety of weights and measures as that now existing in this country and in the United States is in itself sufficient to justify a movement towards reasonable uniformity. There is an official British system of weights and measures, but when trade transactions are concerned its standards are often varied to suit industrial convenience or local custom. A proposal that the British standards should be made compulsory in all transactions, and that no departures from them should be recognised, would evoke quite as much opposition as is now offered by certain industries to the introduction of the metric system. No one supposes that by making the metric system compulsory after a period of years the people as a whole would think in terms of metric units. Local denominations of fractions and multiples of such units are commonly used in all countries where the metric system has been adopted, but they do not interfere in the slightest degree with the larger transactions of trade and commerce.

If the Government adopted the metric system as the sole legal system in all its Departments, and announced that after a particular date all specifications for its work would have to be expressed in terms of that system, a great step would be taken towards its general use. This course and the publication of all official trade statistics in metric terms would lead to similar action by municipalities, railways, and other corporations, and promote the voluntary adoption of metric standards by the trading community generally.

Lamarckism Unashamed.

Initiative in Evolution. By Dr. W. Kidd. Pp. x+262. (London: H. F. and G. Witherby, 1920.) 15*s.* net.

FOR more than twenty years Dr. Walter Kidd has interested himself in the arrangement of the mammalian hair, and pondered over its significance, especially in relation to theories of evolution. He has shown that definite patterns due to the diverse lie of the hair are of common occurrence, that they are subject to change, and that they are hypothetically interpretable on Neo-Lamarckian lines. Whether one agrees with his interpretations or not, one must thank him for a very enjoyable book, written with whimsical humour and with a delightful urbanity in controversy. One admires also the candour with which Dr. Kidd states and seeks to dispose of some serious criticisms brought against his position as expressed in previous books.

A study of the lie of the hair on a cow shows great definiteness; thus it slopes first backwards and then forwards on the neck; behind a whorl over the shoulders it slopes backwards again; along the middle line of the upper part of the tail there is a streak of hairs at right angles.

"Arrangements of its hair so audacious as these need explanation, and it is found in the mode of life of the cow. So large a part of its daily life is spent in the business of grazing with her muzzle close to the ground, during which the neck of the animal is constantly stretched downwards from the back at the level of the shoulders, that the skin, which is very loose in this and most other portions of its body, is dragged upon to allow of the extreme flexion of its neck. This traction is for all this time acting against the normal or backward slope of the hairs, and has given rise to this victory of a new force through a thousand generations. It is equally clear that a mechanical explanation of the line of erect hairs on the first nine or twelve inches of the tail is forthcoming, for one has only to watch a cow standing on a hot day, undergoing her torment of flies, to see it writ large. . . . It is hardly necessary to point out how the underlying muscles would drag upon the skin of the tail over them and gradually reverse more or less the 'lie' of the hairs."

Similar interpretations, often very ingenious, abound in the pages of Dr. Kidd's book. There is an unusual pattern of hairs on man's back; it is to be correlated with his ancestors' habit of sitting with their backs against the side of the cave, or sleeping with their heads raised on some sort of pillow. From between the eyes of a cat the hair on the broad snout slopes downwards, but on a dog's snout it slopes upwards; this is put down to the fact that the dog rubs his head on the

sward from the front of the snout upwards, while the cat dresses her snout downwards with her paw. We should think this was a *hysteron proteron*—the cart before the horse. The dog has on his chest a reversed area of hair—spreading out on each side. "When lying with his head supported on his paws the lower part of his chest is closely applied to the upper or flexor surface of the fore legs, and the long-continued pressure of the latter against the downward or normal streams of hair on the chest leads to its slope being reversed." The downward slope of the shaggy hairs of the two-toed sloth, that spends so much of its time upside down below the branches, is to be attributed to the action of gravity upon the long hairs. We wonder that the author does not allude to the downward pull which the coating of green Algæ on the hairs must involve!

The factors recognised by Dr. Kidd in the formation of hair-patterns are four: friction, pressure, gravity, and underlying muscular traction. His thesis is that changes in the conditions of life —*e.g.* in modes of locomotion and in attitudes of rest—have directly brought about modifications in the lie of the hair, and that these modifications have been cumulatively entailed on the race.

"Initiative in animal evolution comes by stimulation, excitation, and response in new conditions, and is followed by repetition of these phenomena until they result in structural modifications, transmitted and directed by selection and the laws of genetics—a series of events which agree with Neo-Lamarckian principles."

Now it is familiarly easy for Lamarckians to interpret structural peculiarities as the outcome of transmitted exogenous modifications (the direct somatic results of peculiarities in function, habit, nutrition, and environment), and Dr. Kidd is much too thoughtful an investigator to be content with mere interpretation. He brings forward evidence to show that the lie of the hair can be modified in the individual; he also brings forward some evidence to show that parental modifications may reappear in the offspring. Speaking frankly, we do not think the evidence is strong, but it is progress to have any evidence at all.

As regards individual modifications of the hair-pattern, reference is made to the way in which the peculiar functioning of the muscles in the vicinity of the human eyebrow alters its shape and character.

"It is shown by numerous examples in the human eyebrow that the muscles underneath the hairs which are embedded in the true skin for a tangible depth, *do* play havoc with the normal arrangement of hair, as the conflict proceeds, the resultant 'pull' being actually engraved, signed and sealed by physiological wrinkles of the forehead and face."

It may be so, but one must tread warily. There are individual idiosyncrasies in the eyebrows hinted at very early in life, long before the time of wrinkling, which become emphasised when the eyebrow hairs grow longer, as they so often do in later life. First catch your modification.

A little more cogent, it seems to us, is the chapter on the modifications in the hair-patterns of horses, modifications which can be traced to peculiarities of harness. Yet here again there is need for scepticism. One has to be sure that the peculiarities observed are not constitutional variations, quite independent of harness; and here one must go back in Dr. Kidd's book to the excellent treatment of the whorls, featherings, and crests that frequently occur on the horse's neck, most of which cannot, without great difficulty, be regarded as modifications. Moreover, one has to remember that in a hard-worked horse there may be a coercive reversal of the moist hair, which never gets a chance to right itself, and is not, therefore, a true modification which persists after the inducing factors have ceased to operate. As to the ten foals showing a reversed area or pattern on the under surface of their necks similar to that which their mothers showed, we wish to be sure that the maternal reversal was due to the collar. But of the value of collecting cases like this, even if they do not convince sceptics, there can be no doubt, and Dr. Kidd will be thanked by all biologists.

Dr. Kidd supports his case with facts relating to the formation of new bursæ under the stress of mechanical forces and to Pavlov's experimental production of new reflexes in the life of the individual, but he stakes his argument on the lie of the hair. His general position is that initiatives or new departures in evolution are direct answers to peculiarities in nurture (activity, rest, food, and environment), and that these answers are transmissible in a representative way which becomes cumulative, unless, indeed, selection intervenes. He coins the word "plasto-diëthĕsis," combining the metaphors of mould and sieve; the organism is moulded in some new way by peculiarities in function and environment, and the moulded organisms are sifted. "So the banns between Lamarck and Darwin are published, not for the first time of asking, and who shall say that there is cause or just impediment why these two should not be joined in holy matrimony?"

We suspect that the lie of the hair is fixedly determined by the slope of the hair follicle beneath the surface of the skin, and that this slope, though

adjustable temporarily by contraction of the smooth muscles associated with the follicle, is determined by old-established skin conditions—*e.g.* of muscularity, blood supply, and innervation. We should compare the general lie of the hair to the pterylosis in birds, and also, in kind, to the way in which the hairs of different mammalian types occur in distinctive or specific little groups, the members often differing in size. It may be that the vertically upstanding hair of the mole represents a primitive mammalian condition without any lie at all. Whether this be so or not, the lie of the hair is variable, as the study of the horse's neck suffices to show. These variations, comparable to variations in other skin-features—*e.g.* papillary ridges—may be the somatic expression of germinal variations, and it may also be that they are correlated with larger variations of a more obviously utilitarian character. We need not think of them as "anyhow" changes, but rather as more or less consistent with a harmonious viable constitution previously established. In any case, they are the cards put into the hands of the full-grown mammal—cards which he has to play, the result being the sifting out and survival of the "lies" most conformable with the creature's habits. But we cannot prove our Neo-Darwinian theory any more than Dr. Kidd has proved his Neo-Lamarckian one. Some may say not so much.

J. A. T.

Dyes and Dyeing.

Application of Dyestuffs to Textiles, Paper, Leather, and other Materials. By Dr. J. Merritt Matthews. Pp. xvi+768. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 57*s.* 6*d.* net.

THE author introduces his subject with "Craft Dyeing," followed by a short history of dyeing. In discussing tie-dyeing (knot-dyeing), batik and stencil work—some of the earliest methods of producing coloured patterns on fabrics—he makes the rather interesting suggestion that craft dyeing should be encouraged, as the field for it in America is a broad one, because in it "we have the possibility of reaching into realms of colour art that is not present in ordinary trade dyeing." As in the author's former work, "The Laboratory Manual of Dyeing and Textile Chemistry," each chapter is followed by instructions for carrying out experiments relating to the processes described. These should be of considerable assistance to students in technical colleges.

Chap. ii. deals with the scouring of textile fibres. In this an illustration is given of what purports to be an "Open Kier for Treating Cloth with Caustic (H. W. Butterworth and Sons Co.)," which, however, is not a kier, but the preparing and batching arrangement employed in impregnating the fabric prior to boiling in the open-width Jackson kier. The kier proper has been omitted. On pp. 136–37 the author describes the preparation of sodium hypochlorite by passing chlorine gas into caustic soda or soda ash. Bleachers in this country will be interested to hear that "this method of bleaching has come into very extensive use in the United States."

Under "Representative Acid Dyes" (chap. viii.), a "Nomenclature of Dyestuffs" is given. We agree with the author that as regards dyestuffs his task in bringing the information up to date must have been one of considerable difficulty. He is to be congratulated upon this part of the work, and we think he has acted wisely in that he "has deemed it advisable to retain the names and the dyestuffs that were well known before the war, and which could be easily and intelligently recognised in the industry all over the world." The alphabetical list of trade names of the various groups of dyestuffs, in which the class to which each belongs and the manufacturer are given, and the list of the principal dyestuff manufacturers, will be found very useful indeed. A very complete list of all the principal dyestuffs, arranged according to shade, is also given.

In the following chapters the stripping of colours, the testing of the fastness of dyes, and the application of the various artificial and natural dyestuffs are discussed. This is followed by a brief description of the mineral colours, and in the next chapter (which should have been numbered xxiii.) by "Dyeing of Fabrics containing Mixed Fibres." In this some very useful tables showing the affinity of a number of dyestuffs for different fibres are given. The dyeing of other fibres, including linen, jute, and artificial silk, is referred to very briefly. Cellulose acetate silk is not mentioned.

The theory of dyeing is outlined in chap. xxv. It is to be regretted that in this chapter only three references to the literature are given. The name of one of the investigators mentioned should read "Vignon."

The author has compiled an extensive bibliography. The value of this would have been considerably enhanced if references to it had been given in the text. This is an unfortunate omission which it is hoped the author will rectify in a new edition of the work.

The volume contains 303 illustrations of machinery in use in the various operations, but few of these, comparatively speaking, are of American origin. Some of the illustrations which are given in diagrammatical sections are of value to the student, whilst many, which are simply pictures, convey little or no information as regards working details. In a few cases only are the machines fully described in the text.

Forty-one pages are devoted to the dyeing of about twenty-five different materials, including leather, paper, furs, feathers, foodstuffs, etc. In this the author has made an attempt to cover a very wide field indeed, but, as stated in the preface, he has been able to give only "a brief survey of these interesting fields." Some of the information given should, nevertheless, be of value to workers.

In a short review such as this it is unfortunately impossible to discuss the contents of the volume more fully. The book certainly deserves the attention of those interested in the dyeing of textiles and other materials. The amount of information which it contains is very considerable, and it is, therefore, safe to assume that at least some parts of its contents will appeal to every reader. J. HUEBNER.

Time and Space.

The Absolute Relations of Time and Space. By Dr. A. A. Robb. Pp. ix+80. (Cambridge: At the University Press, 1921.) 5*s*. net.

IN 1914 Dr. Robb published a work entitled "A Theory of Time and Space." Bearing in mind the circumstances of that year, it is not surprising to find that the book did not attract a notice commensurate either with the intrinsic importance of the subject or with the novelty of the views propounded in it. The short work bearing the above title is introductory to the larger work, and contains a concise statement of the main results embodied in it. The treatment is very different from that of Einstein. In Einstein's theory the emphasis is laid exclusively on the idea of the "relativity" of experience. Dr. Robb, on the other hand, postulates as the basis of his theory an *absolute* relation—namely, the relation of "before and after." Not only does this relation serve as a physical basis; it is also the foundation on which he builds a goodly structure—his purely geometrical theory of time, of which the theory of space forms a part.

In the first section, devoted to preliminary considerations, the author shows by simple illustrations the difficulty of giving precise meanings to apparently simple concepts such as the equality of lengths, and makes clear the close interdependence of time and spatial measurement. The keystone of his work is to be found in his treatment of the problem of identifying the same instant of time at two distinct points of space. In Einstein's theory each observer carries his own local time, and events which are simultaneous to one observer are not necessarily so when compared by the local time of another. Rightly dissatisfied with this view, the author adopts the bold point of view contained in the statement that there is no identity of instants at different places at all. In his own words, "the present instant, properly speaking, does not extend beyond here." It follows, then, that the complete specification of an instant of time requires the use of four co-ordinates (x, y, z, t).

The author then develops, by means of a system of twenty-one postulates, his four-dimensional geometry of time, and this development is characterised not only by a high degree of originality—particularly evinced in his novel and striking concept of conical order—but also by much skill and insight. Elements of time forming a system characterised by conical order, the spatial aspect, explicitly introduced in postulate v., becomes a direct consequence of this order. Analytically, after co-ordinates have been introduced, the theory leads to Einstein's restricted relativity. The work is a most valuable and original contribution to a very abstruse and difficult subject. More satisfactorily grounded than Einstein's theory, its far-reaching results merit the closest study, not only from the physicist, but also from the geometer. To the latter, indeed, it makes a strong appeal, since, as the author points out, the simple asymmetric relation of "before and after" appears to have important advantages over the concept of "linearly between" which has hitherto been mainly used as a basis for systems of geometry. J. F. T.

Our Bookshelf.

L'Alimentation et L'Elevage Rationnels du Bétail. (*Opinions du Prof. A. Mallèvre.*) By J. E. Lucas. Pp. 466+49. (Paris: Librairie Lefrançois, 1920.) 18 francs.

THE lives of most men of science are divided between teaching and research; he is indeed fortunate who can harmonise the duties. The late Prof. Alfred Mallèvre, whose premature death in 1916 deprived France of a brilliant teacher and keen investigator, seems often to have regretted that his professorial duties left but little leisure for research, and it is sad to read, in the eloquent notice of his career by M. Georges Wery pre-

fixed to the volume before us, that the Agronomic Institute at Joinville-le-Pont obtained suitable laboratory accommodation only when Mallèvre was nearing the end. His devotion to duty did, however, reap the reward of enthusiastic pupils who have introduced scientific methods into fields which they might not otherwise have reached; M. Wery specially refers to the fruitful collaboration between Mallèvre and M. J. E. Lucas, whose notes of his professor's lectures have been published. The book is indeed a clearly and practically written treatise on the physiology of animal nutrition suitable for any intelligent student in a school of agriculture.

The first eight chapters deal with the general principles of the subject, and cover ground fairly familiar to the student of general animal physiology. Mallèvre was a definite adherent of the isodynamic school, and subjected Chauveau's experiments to searching criticism.

Chaps. ix. and x. are of particular interest to the farmer, and Mallèvre's tables, based upon Kellner's methods, should be of great use.

In the chapters which follow, the effects of exercise, environment, and heredity upon farm animals are considered, and the work concludes with a short, but clear, account of methods available for the protection of stock against infectious diseases.

Had the author himself lived to publish a textbook, he would probably have devoted rather more space to recent work upon accessory food substances, and perhaps have made more use of American work on calorimetry. The chapter on heredity also needs some revision. These are, however, minor points; taken as a whole, the book is well adapted to the purpose for which it was designed.

Rapid Methods for the Chemical Analysis of Special Steels, Steel-making Alloys, their Ores and Graphites. By C. M. Johnson. Third edition, revised and enlarged. Pp. xi + 552. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 36*s.* net.

THE number of elements employed in the manufacture of alloy steels appears to be ever increasing, and to it there have been added, during the last few years, cobalt, uranium, zirconium, and cerium. Accordingly, a new edition of the above work, embodying the latest American practice in the analysis of such steels and of the alloys used in their production, is very welcome.

Amongst other features which the one hundred pages of new matter contain are: A new and original method for the determination of sulphur; the partial separation of iron from such elements as vanadium, uranium, zirconium, and aluminium by a process which dispenses with the "ether separation"; important modifications of older processes; illustrated descriptions of new forms of laboratory appliances; and a chapter on micrographic analysis.

Repetition of unnecessary details and more than a few obvious mistakes betray a somewhat hasty preparation, and, moreover, the arrangement of the whole subject-matter leaves much to be desired, though the last defect is remedied to some extent by a good index and numerous cross-references. Steelworks' chemists, at any rate, will doubtless overlook deficiencies of this nature in a book which emanates from such a trustworthy, experienced, and original worker as its author.

Stones and Quarries. By J. Allen Howe. (Pitman's Common Commodities and Industries.) Pp. x + 137. (London: Sir Isaac Pitman and Sons, Ltd., n.d.) 3*s.* net.

MR. HOWE is specially qualified among geologists by his economic studies at the Jermyn Street museum for writing a book on stones and quarries that will interest the general reader. Such readers constitute the bulk of intelligent persons, who prefer to understand what they meet with on their travels and are not content with mere wonder at the wealth of the earth and the ingenuity shown in its exploitation. Mr. Howe begins by showing the æsthetic feeling for cut stones among the Egyptians 7000 years ago, and the gradual development of carved and polished work by race after race, down to the cathedral builders of western Europe. "Porphyry," by the by, was practically unknown to the Egyptians, and one would scarcely gather, from the associations ascribed to it on p. 3, that the Taj Mahal was a work of the seventeenth century. Two felspar formulæ on p. 10 have escaped proof-correction, but these are only trifling criticisms. The numerous views of quarries in active operation, and the description of the machines used, open up a new and healthy field before the professional petrologist. The use of columnar basalt for road-setts in Italy and for the retaining walls of canals in Holland might be added to Mr. Howe's instances of the applications of rock-structure to human needs. G. A. J. C.

The Chemistry of Synthetic Drugs. By Dr. Percy May. Third edition, revised. Pp. xv + 248. (London: Longmans, Green, and Co., 1921.) 12*s.* 6*d.* net.

VERY few changes have been made in this work since the first edition, reviewed in NATURE for September 21, 1911, was published. The third edition, which is now issued, follows closely on the heels of the second, and, indeed, the publication of information gained during the war in the chemistry of poisons, irritants, etc., appears to constitute the greater part of the alterations which have been made. The poisonous nature of most poly-nitro-compounds has been completely established, and new facts relating to other toxic substances, such as phosgene and mustard gas, which were used by the belligerents are recorded. The volume will no doubt be found extremely useful by those engaged in the manufacture of synthetic drugs.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Earth-worms, Mud-worms, and Water-worms.

I GATHER from various correspondents that the word "earth-worm" requires some elucidation if we are to avoid misconception. I venture to submit the following statement. The Chætopoda, or bristle-footed worms—often called the "Annelids"—form one of the three large branches of the phylum Appendiculata. The Arthropoda (=Gnathopoda) and the Rotifera are its two other branches. The Chætopoda are divisible into the class "Polychæta" (all marine) and the class "Oligochæta"—containing very few marine forms, and inhabiting either the slime and mud of fresh-water pools and streams, or the loose, damp "humus" or "earth" of the land-surface.

I think that the opinion expressed by Mr. Coste (in his valuable letter in NATURE of May 19, p. 360), to the effect that "the moist surface" of worms inhabiting the soil "must, when underground, frequently or usually be in contact with other moist surfaces, so that the worm is, in effect, partly immersed in water," involves a mistake as to the condition of the earth thus inhabited and the size of the burrow made by the worm. The earth inhabited by earth-worms is *not* slime or mud, and does not fit closely to the worm's body as would a semi-liquid mud or soft clay. It is, on the contrary, a loose aggregation—the solid particles of which are largely separated by atmospheric air—and the worm's body does not fit tightly to the walls of its burrow, although a mucous exudation from the worm's surface is often deposited on those walls. An earth-worm in movement is continually changing its dimensions—elongating and becoming narrow, shortening and becoming wider. Hence there is no "immersion" of the worm's body in liquid or semi-liquid material. On the contrary, air has continual access to the worm's surface through the *porous* soil; and the change in its diameter and its movements must cause the movement of the air in the space between the worm's body and the wall of its burrow. It seems to be necessary to bear in mind the distinctive physical features of the earth or surface soil in which the earth-worms make their burrows—as contrasted with either the water or the mud—practically a liquid—in which other Oligochæta pass their lives.

The Oligochæta are divided into four orders, namely, the Naidiformia, the Sænuridiformia, the Lumbriciformia, and the Hirudiniformia (or leeches). The first of these is a very distinct group inhabiting fresh-waters (only two British species are marine). They are much smaller in size than the others, and are characterised by young forms which reproduce abundantly by bud-fission, and are succeeded by a distinct adult sexual form. The Sænuridiformia and the Lumbriciformia are closely allied—the former being as a rule smaller, more elongate, and more agile in movement than the latter, and less familiar to the inexpert observer. They inhabit fresh-waters (a few only are marine) and the mud or slime of fresh-water pools of brackish estuaries and of sluggish streams, whilst the Lumbriciformia are large worms with opaque, thick body-wall, which forcibly burrow in loose, air-holding earth, and have, as a rule, a close resemblance to our common earth-worm in shape, colour, and habits. The larger Sænuridiformia, such as Lumbriculus and Phreoryctes, have the brown-red colouring of earth-worms, and, although differing in shape and movement from Lumbriciformia, are liable to be mistaken for young earth-worms when appearing, as they sometimes do in great number, in the reservoirs and mains of water-supplying companies.

The Lumbriciformia comprise a great number of genera distinguished by peculiarities of their reproductive apparatus, their renal organs (nephridia), and the gizzards and other parts of the digestive canal. They have as a rule a specially rich supply of blood-vessels to the integument which serves as a respiratory organ. This special blood supply is not present in the Sænuridiformia, which have, however, well-developed, deeper-lying vascular trunks holding hæmoglobinous fluid.

The word "earth-worm" is often applied to the whole group of Lumbriciformia, which are contrasted as "Terricola" with the Sænuridiformia, for which the term "Limicola," or "mud-dwellers," is used. There are good reasons, however, for limiting the word "earth-worm" to the common English earth-worm, *Lumbricus terrestris*, and the few closely allied species of Lumbricus. Those reasons come to our notice when we are considering the possible drowning of the common earth-worm and the respiratory conditions connected with that mishap. They are, first, that a whole family of Sænuridiform worms is known—the Enchytræidæ—which are *not* water-dwellers or mud-dwellers (Limicola), but live in humus and amongst dead leaves, and are, in fact, just as much "Terricola" as are the commoner Lumbriciformia. And, secondly, there are at least two genera classed with the Lumbriciformia which live, *not* in the earth, but in open water. One of these is the *Criodrilus lacuum* (occasionally found in England, but common in Central Europe), which has the appearance, size, and inner structure of the Lumbriciformia—and, indeed, is a close ally of Lumbricus; and the other is the *Alma nilotica* or *Digitibranchus niloticus*, which not only lives entirely in the water, but is also provided with a series of filamentous, naked branchiæ containing a blood-red vascular fluid. I am not able to state whether Criodrilus has or has not a tegumentary blood supply. It has not, I think, been studied from this point of view. There is no full account (so far as I can ascertain) of the structure of *Alma nilotica*, nor have illustrations of its anatomy been published, though systematists have given brief accounts of this and allied species.

I think, then, that it is clear that we must not extend the implications of the word "earth-worm" when discussing details of structure and physiological adaptation beyond the particular species which has been the actual subject of study. In writing here of the drowning of earth-worms I have intended my statements to apply only to the common British earth-worms called *Lumbricus terrestris*. Probably they are true of many other Lumbriciformia, but that is only a supposition which must be tested and must not be held as fact until proved by further examination to be so.

E. RAY LANKESTER.

P.S.—I find that Vejdowski has described a rich network of capillary blood-vessels in the integument of Criodrilus (a Lumbriciform), and that in *Limnodrilus Hoffmeisteri* (a Sænuridiform) he has found capillaries in small groups of four, ending blindly in the epidermic cell-layer. Such capillaries in the integument are, he says, absent, as a rule, from all Oligochæta except the Lumbriciformia.

E. R. L.

Biological Terminology.

I think Dr. Bather (Nature, May 5, p. 301) and I may be using our words with unlike meanings, but he raises an important point. To use my own meanings: we describe when we say what a thing is like; we interpret when we account for it. Both these processes imply classification (*i.e.* identification); both are necessary in science; one is not superior or inferior to the other; but they are different. In description we classify facts and objects according to co-existences and resemblances. Thus, when we term a man a mammalian vertebrate we say, in effect, that in him mammæ and vertebræ co-exist, and that therein he resembles other animals. Is not all systematic zoology and botany founded on this kind of classification, a beautiful example of which may be found in the address of any letter sent by post—addressed to a man with a certain name, in a certain house, in a certain street, and so on? On the other hand, when we interpret we explain, we link cause with effect, we formulate suppositions, hypotheses, theories, we trace the connection between antecedents and consequents, we try to understand. Thus we class together such unlike things as the fall of apples, the rise of tides, the swing of the pendulum, and the motions of the planets by saying that they furnish instances of gravitation; we account for teeth and mental faculties by attributing their evolution to natural selection; we identify the blacksmith's muscles, mathematical and golfing skill, and acquired immunity against disease as results of functional activity. From the nature of the case there is little or nothing of this sort of thing in systematic zoology and botany.

Description and interpretation are the warp and the woof of science. The former must always precede the latter, for we cannot account for things until we know what they are like. Some sciences (*e.g.* mathematics and physics) are based on few facts. Thus all the facts on which geometry is founded consist of its axioms and some of its definitions. Necessarily, therefore, this science quickly passed in its evolution from description to interpretation, and its students in their mental development quickly tread the same path. Their main training is in interpretation. They have little knowledge of facts, but great skill in a particular department of thought. Other sciences (*e.g.* zoology and botany) deal with an enormous number of facts; ages must pass before they are at all adequately described, and every student must spend years in acquiring them. His main training, therefore, must necessarily be in description. He acquires a vast knowledge of facts, and, therefore, since he knows what to look for, becomes a trained observer. A mathematician may be an excellent observer, but this skill does not necessarily flow from his specific training. Indeed, it is remarkable within what narrow limits his skill may avail him—just as training in a game (*e.g.* golf) may develop the student's skill only in that particular game. Similarly, though any zoologist or botanist may be a skilful interpreter, skill of this kind does not necessarily flow from his specific studies. This is all that I meant by the statement to which Dr. Bather takes exception.

Man is the educable animal, but he is also the forgetting animal. The things he particularly tends to forget are facts. The things he tends to retain are mental habits, among which are dexterities in thinking and doing. These dexterities, learned slowly and with toil, are even more slowly lost—as in the case of the mathematician and the cricketer. As a schoolboy I received some training in mathematics; to-day the mathematical books in my library are nearly useless to me. Some part of them is at my fingers' ends; the rest I cannot understand. As a medical student I had to cram for examinations what seemed an enormous number of facts about botany and zoology. Almost all that is lost, but I can recapture any of them by reference to my books. Evidently it is sometimes better to teach good mental habits than to impart mere knowledge. No attempt was made to account for the facts of natural history to me (to train me in interpretation), but, fortunately for my future pleasure and interest in life, I had antecedently read Darwin. I doubt whether any of my contemporaries were as lucky. I do not know whether teaching has improved since my day; but this I do know, that while the facts of interpretative biology are abundant, its hypotheses innumerable (more than two hundred explanations of sex alone have been formulated), and its controversies unending, it has, unlike physics, for instance, next to no established truth. I know also that its terminology is so loose that it is often used with no meanings or with contradictory meanings, that its hostile sects ignore one another's evidence, and that all sects unite in ignoring evidence derived from other sciences. There is, in fact, no general use of crucial testing, which is the only means by which people of divided opinions can reach a common platform and hypotheses be examined in the light of all the evidence. I know besides that it is harder to interest biologists in the big question of biology, or in any questions not purely sectarian, than it is to interest anyone else.

This question of crucial testing is important. Probably it lies at the root of most of the troubles of interpretative biology. Given crucial testing, not only would all the relevant facts be brought into court and hypotheses be proved and, if correct, established, but also the necessity for a correct terminology would become clear. Dr. Bather will perhaps forgive me if I become tedious in stating elementary, but neglected, truth.

Proof of a descriptive statement is furnished by the facts on which that statement is founded. Thus, to establish the truth that man is a mammalian vertebrate it is only necessary to indicate the breasts and the backbone. On the other hand, an hypothesis can be proved only by fresh, unlike, crucial facts—facts of such a nature that every alternative supposition is shown to be inconceivable as true. "When the hypothesis of itself, and without adjustment for the purpose, gives us the rule and reason of a class of facts not contemplated in its construction, we have a criterion of its reality which has never yet been produced in favour of falsehood." For example, if I lost coins and supposed that Mary the servant had stolen them, I should be only guessing. But if, in addition, I planted marked coins and found them in her possession, I should have proved my case with a high degree of probability. Outside biology all interpretative science is founded on adequate crucial testing—which implies an acceptance of the maxim that all relevant and verifiable facts, no matter how collected (by direct observation, experimentally, statistically, and so on), are equal before science. Thus, in effect, Newton and his successors said to themselves: "If the theory of gravitation is true, stones must fall at certain rates of acceleration, tides must follow the moon, pendulums must swing in certain times, planets must trace certain orbits, worlds must assume certain shapes," and so on, until not only was the supposition established (by disproving alternatives), but also a universe of diversified facts has been brought within its range. Hence its importance. If to-day I said to physicists, "Your terminology is loose and your scientific methods four hundred years behind the times," what would happen? I think they would

take me between finger and thumb and eat me like a shrimp.

At least one great biologist, Darwin, tried to test his supposition with Newtonian candour and thoroughness. So far as I am able to judge, disbelief in natural selection is now felt only by people who decline to submit their opposing suppositions to a similar course of rigorous testing. But, to judge from literature, as a general rule, biologists seem to think that, as in description, the facts (or similar facts) on which an hypothesis is founded sufficiently prove the truth of it. Hence, in the lack of crucial testing, the chaos of opinions. Hence the rival doctrines and schools. Hence the unending controversies. Hence the absence of truth accepted by everyone. Hence the particular value set by this sect or that on evidence collected in this way or that, and the neglect of all other evidence. Hence, its inaccuracies undetected, the perpetuation of a loose terminology. Hence, for example, the two hundred explanations of sex. All these explanations must have been guesses; or, if one was fully tested and established, biologists have not recognised it. Biology is happy in the possession of vast and diversified arrays of facts suitable for crucial testing. Biologists are unhappy in that they do not use them. Their scientific methods are four hundred years behind those of physicists, and I suppose four thousand years behind those of mathematicians. I think all biologists must agree to this, if not as regards themselves, yet as regards the prejudiced adherents of rival sects. Crucial testing is the very soul of interpretative science. It is that which guides and controls the scientific imagination. But, as religious enthusiasts, politicians, and some men of science demonstrate, if you have not been trained to use it and submit to it, it is often nothing to you.

May I, by way of example, give one instance of what appears to me wasted opportunity? I choose a subject which does not seem to have gathered sectarian odium. It is not especially easy as biological problems go. I imagine every other problem now in dispute could be solved as simply if crucial testing were employed and its results accepted. Judging from embryos, some biologists have concluded that the individual in his development recapitulates the evolution of his race. On the same, or similar, evidence other biologists have reached a contrary conclusion. Both opinions are mere guesses, and, used in this way, the facts afford no opportunities for crucial testing. But consider them from another aspect. Consider the evolution of a structure—for example, an antler—in a line of individuals A, B, . . . Y, Z.

The first rudiments of the structure appear in A. The structure increases by progressive variations in B, C, . . . L, M. But B cannot produce his own variation without recapitulating that of A. C cannot achieve his development without recapitulating first A and then B. M cannot develop without reproducing in turn every ancestor up to A. To this point the development must necessarily have been an accurate recapitulation of the life-history of the race. But now N varies retrogressively—that is to say, he omits some part of the development, and therefore of the evolution. If N reverts to K, L and M disappear from future editions of the life-history, which thus becomes inaccurate. O resumes the progression. P interpolates a variation (*e.g.* the beginning of a tine) at the stage reached by F, introducing another inaccuracy. So the evolution continues until in Z the development, recapitulating not only some of the original history, but also many additions and subtractions, presents only a vague, inaccurate, foreshortened outline of the evolution—most vague, as a rule, in its earlier parts, which have been most often repeated, and, therefore, subjected to most alteration.

There is a history in all men's lives
Figuring the nature of the times deceased.

This history is not told in words, but in graphic signs, in mimicry; and like a written history, copied by a thousand hands and altered to suit the times, it has become inaccurate.

To put the thing in others words: if the son copies with alterations the development of the parent, if the parent copied the grandparent, and so on up to the remotest ancestor—the unicellular represented by the germ—how is it conceivable that development can be other than a recapitulation, however inaccurate, of evolution? But inconceivability is not sure proof. It may result from the incapacity of the thinker. Turn, therefore, to crucial testing, for which facts are now available. If it be true that development is inaccurate and incomplete recapitulation, embryos should present the appearances, however vague, of ancient ancestral types. This is exactly what we find. Consider a butterfly. It begins life in the egg, where, quiescent and sheltered, it develops in an environment very unlike that in which the ancestral prototypes struggled for existence. At this stage, therefore, recapitulation should be much altered, vague, rapid, foreshortened, a mere scaffolding. The caterpillar must fight actively for existence in an environment which probably resembles closely that of its prototypes. Probably, therefore, the animal itself closely resembles its prototypes. It increases in bulk, but otherwise changes little. Quiescent and sheltered, a chrysalis, on the other hand, alters rapidly and enormously except in bulk. In the butterfly development has ceased. In man, sheltered and quiet in the uterus, there undergoing vast changes, but afterwards altering little save in bulk, development pursues the same lines. So also in every other type of multicellular being. Consider how sheltered is the development and how rapid the recapitulation in the seeds of plants, and how small, relatively, are the subsequent alterations, except in bulk.

If anyone can now think of development as other than recapitulation, he is capable of an intellectual feat beyond my powers. If I am right, I have furnished evidence that it is possible to solve even the more difficult biological problems by paying attention to the ordinary rules of scientific procedure. If I am wrong, biologists should, like the physicists, be able to eat me like a shrimp.

Here is a significant thing. No man of science, not a biologist, who knows the facts and has read what I have written will ever again be able to conceive of development as other than recapitulation; and often, when he thinks of a seed, an egg, an embryo, or a chrysalis, he will wonder what æons are being traversed within these amazing time machines—the "resting stages" of the biologists. But no biologist will be interested or will alter his antecedent opinions a hair's-breadth. He will merely be shocked at the impudence of one who is neither a botanist nor a zoologist.

The Great Sun-spot Group and Magnetic Disturbances, May 8–21.

On May 8 there appeared on the sun's eastern limb an equatorial sun-spot in a region which has been without disturbance for some considerable time. It was an active spot which had separated by May 12 into two large spots. The maximum area of the group was 16·5, in units 1/5000 of the sun's visible disc, and this was attained on May 14. The leader spot of the group was a composite spot containing two umbræ.

Its mean heliographic co-ordinates on that date were latitude $+1\cdot4°$, longitude $6\cdot4°$. The following spot was a large single spot, and its co-ordinates were latitude $0\cdot2°$, longitude $358\cdot8°$. The whole group extended over 12° in longitude and about 6° in latitude, so that a considerable area of the sun's surface was disturbed.

The mean heliographic latitude of the earth during the passage of the group across the sun was $-2\cdot8°$. Therefore, not only was there a large active sun-spot on the sun, and with the penumbral character which frequently marks spots associated with magnetic disturbance, but also the earth was very favourably situated with regard to it. Under such conditions a great magnetic storm is inevitable.

With regard to the registration of the movements of the needles during the series of magnetic disturbances, we were greatly handicapped by the non-arrival of our usual supplies of sensitive photographic paper. Even so, on the less sensitive paper we were obliged to use the records were very remarkable. As early as May 11 the D (declination) magnet was affected by some small rapid oscillations from 6h. 12m. to 8h. 12m. The next day, May 12, between 8h. and 10h., D was still more disturbed, while at 8h. 12m. H (horizontal force) showed a marked and rapid fall of 146γ.

A greater activity of disturbance began on May 13 with a "sudden commencement" at 13h. 12m. In D there was a rapid movement to east and west of extreme range 15°, and on V (vertical force) an increase, decrease, and rapid recovery, range 26γ, in about two minutes. This phase is somewhat unusual on V. Between 21h. 24m. and 21h. 36m. a rapid oscillation of D occurred, east, west, and east, range 28′. At the same time V fell rapidly and suddenly 333γ, recovered for a few moments with a slight rise at 21h. 36m., and then fell so that the spot of light was off the recording drum. At 22h. 12m. it rose again rapidly 250γ. Just before midnight there were further active movements of D and of V.

The second and more intense phase of the storm commenced on May 14 16h. On D a series of oscillations occurred of increasing speed and amplitude until 22h. 22m., when there was a sharp eastward movement of 46′. At the same minute there commenced a very rapid decrease of force in V of at least 461γ, the spot of light passing off the paper on May 15 0h. 24m., the magnet adhering to the arrests. It did not begin to give a record again until May 15 9h. 12m., when it had risen to its position before the rapid fall.

Meanwhile D was becoming more violently agitated until on May 15 0h. 45m. the spot of light passed off the drum in an eastward direction. This marked the commencement of the third, or most intense, phase of the storm, which lasted for about eight hours. The movements of D were so rapid that the paper used was not sensitive enough to register all their details. At 5h. 24m. the spot of light had reached the limits of record in the westward direction, so that the extreme range of D during the storm was greater than 2° 9′. It was not until 7h. 30m. that the movements had decreased in intensity sufficiently to be clearly legible on the curves. The spot of light was then east, and it rose west with a series of rapid oscillatory movements between 8h. and 11h., when it attained a normal position. The mean range of these oscillations was 20′.

With regard to H, the trace after May 14 22h. 25m. and during the maximum phase is completely lost owing to the inferior sensitiveness of the paper. The record is resumed on May 15 7h. 30m. This agrees with D in giving the greater and greatest intensities of the storm as occurring between May 14 22h. 25m. and May 15 7h. 30m.

On May 16 D continued to be disturbed, particularly between 0h. and 11h., with a range of 47′, the more rapid oscillations taking place between 4h. and 10h. This is a repetition as to time of the storm of the preceding day, though on a reduced scale. On H the activity was even greater than on D, the range being 329γ. On V the spot of light fell gradually, until on May 16 6h. 50m. it had passed off the paper. It came on again after about 12 minutes, and the magnet gradually resumed a normal position. The range was 410γ. The character of its trace was a long wave with superposed oscillations. During the storm the variations in V were extremely and unusually active.

Magnetically, May 17 was comparatively, though not actually, a quiet day, and May 18 was even quieter. Greater activity was resumed on May 19 20h., when the sun-spot, much reduced in disc-area, was approaching the western limb of the sun. Between 23h. and 23h. 46m. there was a well-marked peak-like movement on D, with a range of 58′. H was not so much disturbed as D. But on May 20 23h. 5m. to May 21 0h. 5m. there was a movement on H of a similar peaked character to that of D on the preceding day. The range was 212γ. V, too, was again active, range 173γ, between May 19 21h. and May 20 3h. 30m. On May 20 14h. 30m. there was resumed activity on the magnets, with rapid oscillations on D and H and an increase of force in both H and V. The series of disturbances, constituting a storm of unusual duration, had not completely subsided until May 21 20h. A. L. Cortie.

Stonyhurst College Observatory, May 27.

The Reparation Act and Scientific Research.

Prof. Partington's letter (Nature, May 26, p. 394) interested me, because some months ago I pointed out in Nature how harmful any restriction of the importation of scientific apparatus would be to some scientific laboratories, and how unreasonable the claims of the English instrument-makers appeared to me. However, no one else wrote in support of what I said and several makers wrote against it (though carefully refraining from answering my criticisms), and I almost began to think that my experience might be unusually unfortunate and that other workers were not affected, especially as Nature in certain leading articles supported the protection of "key industries." The Gilbertian "Reparation" Act is of later date, but instances of its working are supplied in the letters of Prof. Gardiner and Prof. Partington.

Now there is not the slightest hope that the weak influence of scientific workers will affect the plans of practical politicians and Civil Service officials, especially after the recent action of the Post Office when opposed by much more powerful interests. Nevertheless, I am surprised that none of the scientific societies has taken the action of ascertaining the feeling of its members on this question. They could then either repudiate the statements of the grumblers, of whom Prof. Partington may be reckoned one, or publish some manifesto which could be placed on record as a protest against the policy of protecting scientific apparatus at the expense of science.

It is reported that the president of the Society of Glass Technology, speaking on the restriction of importation of glassware, considered that "electric lamp bulbs should also have been included in the Bill," and I agree, as that might have attracted more public attention to the effects of the Bill.

The Cosmology of Dante.

By DR. J. L. E. DREYER.

THE study of the cosmological ideas set forth in Dante's great poem is of considerable interest, not only because it helps us to understand many parts of the poem which otherwise might appear obscure, but also because Dante is a faithful interpreter of the opinions about the construction of the universe which were prevalent in his day. In this respect he is unique among poets. In the present article we shall trace the origin and gradual development of the system of the world adopted by Dante, without entering on minute interpretations of particular passages.

The principal feature of this system is the arrangement of the universe in a series of concentric spheres with the earth in the centre (Fig. 1).

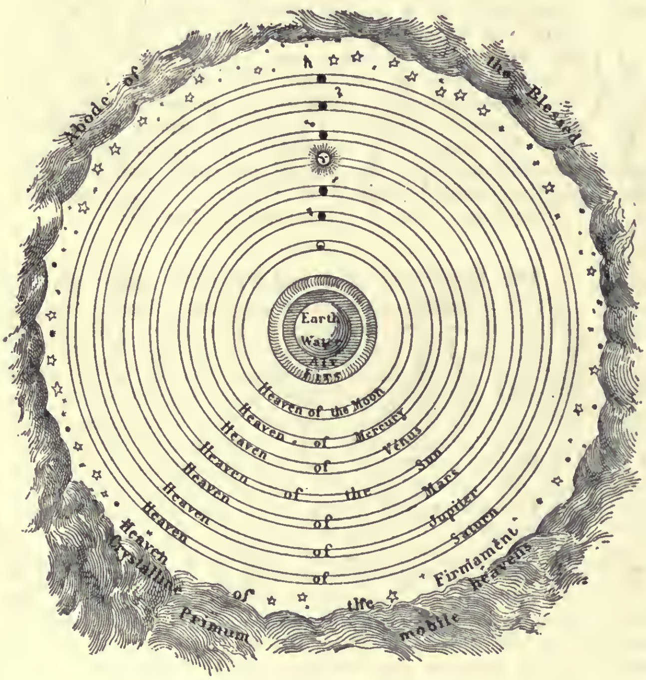

FIG. 1.—Dante's cosmical system.

This is a very old idea, originating in the most striking of all celestial phenomena, the rotation of the heavens in twenty-four hours from east to west. Eudoxus (about 370 B.C.) was the first to design a complete system of concentric spheres, arranged so as to account for this rotation of the heavens as well as for the principal irregularities in the motions of sun, moon, and planets in the opposite direction. Though Eudoxus was a great mathematician, his system of spheres could account only partially for the observed phenomena, probably because it was founded on an utterly insufficient number of observations of these phenomena. The system was much improved by Kalippus, and, what was of more importance, it was accepted by Aristotle. To him the spheres were not merely mathematical conceptions, but physically existing bodies, kept in motion by the soul of each. Notwithstanding his great authority, however, this system was rejected by the astronomers of Alexandria, chiefly because it suffered from an incurable defect, that of assuming every planet to be always at the same distance from the earth. That this is not the case is clearly shown by the variable brightness of the planets, most strikingly seen in the case of Venus and Mars.

The increased number of apparent irregularities in the planetary motions revealed by steadily pursued observations led to the development of a system of the world which finally became known as the Ptolemaic system, because the last touches were put to it by Claudius Ptolemy in the second century A.D. It assumed a planet to move on a circle, the epicycle, the centre of which moved on a larger circle, the eccentric, near the centre of which the earth was situated. Additional refinements were added to account for observed minor irregularities. But all this, though very satisfactory to mathematicians, was not to the taste of many people, who could not accept all these circles as realities, but demanded some sort of a system of spheres, not necessarily concentric. To satisfy this demand it was suggested that we might for the epicycle substitute a small sphere, to the surface of which a planet was attached, while the sphere fitted in and moved between the surfaces of two concentric spheres, near the common centre of which the earth was placed. Ptolemy, who wrote a valuable text-book on astronomy (the "Syntaxis," generally known by the Arabic name "Almagest"), wrote also, for the weaker brethren, another, called "The Second Book of Phenomena," in which a complicated system of spheres is described. But this was never a success, and the Greek original is lost, so that the book was quite unknown to modern European readers until 1907, when a German translation from an Arabic version was at last published.

Among the Arabs we find an attempt to adopt material spheres in the cosmical system of the "Brethren of Purity," a semi-religious society which arose at Basra near the end of the tenth century. They taught that there are nine spheres of different thicknesses, fitting inside each other "like the skins of an onion." The ninth sphere is the prime mover, and turns in twenty-four hours. The eighth sphere is that to which the fixed stars are attached; it revolves in a very slightly longer period, lagging behind to the amount of one degree in a hundred years. This is supposed to account for the precession of the equinoxes. Saturn (the seventh sphere) lags more, and the motion becomes slower as we descend through the spheres, until we reach the first or slowest sphere, that of the moon, which takes

about fifty minutes more than twenty-four hours to make a complete revolution. In other words, all celestial motions take place in the same direction, from east to west. This is a very old idea, several times alluded to by Plato; but the denial of the independent eastward movement of the planets could not commend itself to any Greek astronomer who realised that the planets moved in orbits considerably inclined to the direction of the daily rotation. This was also the case among the Arabs, and no prominent advocate of a system of spheres appeared among them until the rise of the Aristotelian philosophy in Spain in the twelfth century revived the belief in spheres. Al Betrugi (Alpetragius) wrote a book on the subject, in which he also let all the motions be from east to west. But though he made some attempt to account for the most conspicuous irregularities of the planetary motions, his system is not to be compared with the Ptolemaic system as regards completeness, and it could be accepted only by people who were content merely with the rough outline of a system.

Early in the thirteenth century Arabian books on philosophy and science began to be known north of the Pyrenees, and along with them came the writings of Aristotle, translated long before from Greek into Arabic, and now from Arabic into Latin. As Aristotle, who very soon was accepted as an infallible guide, had adopted a system of spheres, one outside the other, it was very difficult for his Christian admirers to do anything else. During the whole of the thirteenth century there was a running fight between the adherents of Aristotle (or Alpetragius) and those who realised that no system of concentric spheres could ever account for the observed phenomena so completely as the Ptolemaic system of epicycles and eccentrics did. By the year 1300 the fight was in France fairly well decided in favour of the followers of Ptolemy. But in Italy the study of science had scarcely made any progress; Ptolemy's great work (though translated into Latin as early as 1175 by Gherardo of Cremona) was quite unknown, and only an extremely elementary text-book by Al Fargani was used in the universities.

It was therefore natural enough that Dante should be persuaded of the truth of the doctrine of concentric spheres. Besides, this readily lent itself to poetic treatment, which a complicated set of circles could never do. There is no trace, either in the "Commedia" or in the philosophical treatise the "Convivio," of his having known the "Syntaxis" of Ptolemy. The chief source of his astronomical knowledge is the little text-book of Al Fargani, which he frequently quotes, and from which he occasionally borrows whole passages. In the "Convivio" he repeatedly makes use of the writings of the great scholastic, Albertus

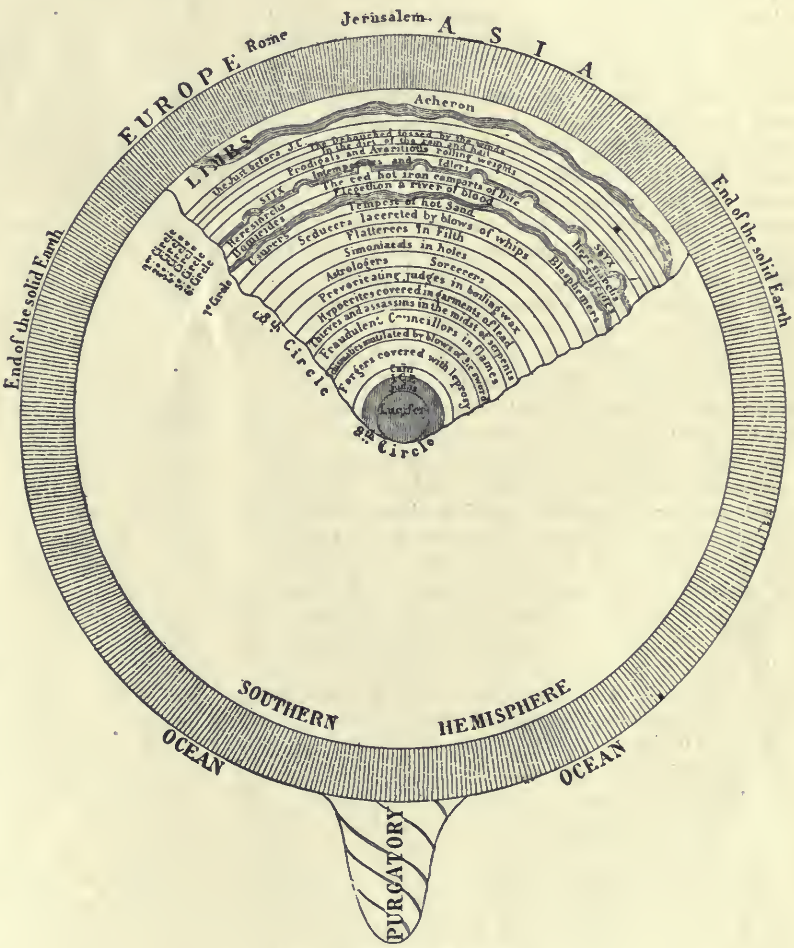

FIG. 2.—Dante's infernal regions.

Magnus. In contrast with several Italian writers on astronomy even long after his time, who often displayed great ignorance, Dante shows himself well acquainted with the general phenomena of the heavens. Thus he describes correctly the apparent motions of the stars as seen from the poles of the earth or from the equator; he often indicates the time of year by mentioning the zodiacal sign occupied by the sun; he even gives a fairly closely correct value of the length of the year.

In the centre of the universe is the earth, which is a sphere. These two facts were not disputed

by anybody. Hell is a conical opening reaching to the centre of the earth, where the devil dwells at the apex of the cone (Fig. 2). Among theologians this was generally accepted as the proper place for him. Even three hundred years later, when the motion or non-motion of the earth was the burning question of the day, the idea appeared very shocking to many that a body having the devil in the middle could be supposed to travel among the heavenly bodies, which were moved by angels. Purgatory is a large conical hill, rising out of the vast ocean at a point diametrically opposite to Jerusalem, the navel of the dry land. The heavenly spheres, ten in number, surround the earth, and they are repeatedly alluded to as being solid. In each of the first seven spheres spirits, though they have not their permanent abode there, appear to Dante in order to illustrate the gradually increasing glory which they have been found worthy to enjoy, and to indicate their former earthly characters, which had been chiefly influenced by one of the seven planets. The shadow of the earth reaches as far as the third sphere, and the spirits seen in the spheres of the moon, Mercury, and Venus have the lowest degree of bliss in the Empyrean.

The tenth sphere, the Empyrean, is the dwelling of the Deity. It is motionless, because all motion implies change and a desire for something better. The ninth, or crystalline, sphere is the prime mover, endowed with circular motion which expresses its praise of the Creator, and by its almost incomprehensible speed it shows the desire of each part of it to be joined to the Empyrean. The eighth sphere is that of the fixed stars; it has a very slow eastward motion of its own of one degree in a hundred years (precession), and transmits the daily rotation received from the ninth sphere to all the lower spheres. Dante seems, however, to have been somewhat uncertain about the source of rotation: in one place in the "Convivio" (ii., 15) he attributes both rotation and precession to the eighth sphere, though he immediately afterwards returns to his usual theory; and in another place ("Convivio," ii., 6). when speaking of Venus, he says that "whether the daily movement comes from some intelligence or from the onrush of the prime mover, God knows, for it appears to me presumptuous to decide." But these passages seem only to indicate some momentary hesitation between the conflicting statements of his sources. In the same way he is doubtful about the nature of the Milky Way, whether it is composed of stars or of vapour. He is particularly disturbed by the difference between the "new" translation of Aristotle (by Thomas Aquinas, from Greek) and the "old" one (by Michael Scot, from Arabic), but he inclines to the statement of the latter, that it is a multitude of stars.

The nine revolving spheres are moved by the three triads of angelic intelligences, the Seraphim as the highest in rank directing the ninth sphere, while the angels govern the lowest sphere, that of the moon. The planets were supposed to move in the plane of the ecliptic. There is no mention of the motion being eccentric, though Dante must have seen the account of the eccentric circles given in Al Fargani's book. But these were inconvenient things to believers in a system of spheres, and were better ignored. On the other hand, there are several allusions to epicycles; thus it is said in a paragraph in the "Convivio" (ii., 4) about Venus that on the circle of its sphere there is a small sphere which astronomers call an epicycle, "and though we say that there are ten spheres, this number does not comprise them all."

The last and lowest of the ten spheres is that of the moon. While the motion of Saturn is the swiftest, because this is most divine motion, that of the moon is the slowest ("Paradiso," iii., 51). The revolutions of all the nine spheres are therefore from east to west as supposed by some of the early Greek philosophers and by all the Arabian believers in spheres. As to the nature of the moon, and particularly of the surface-markings, Dante, in the "Convivio" (ii., 14), adopts a theory, due to Averroes, according to which the spots are caused by the rarity of some parts of the moon's body which do not reflect the sun's rays well. But in the "Paradiso" (ii. and xxii.) this is objected to, and the spots, which Dante, looking from above, sees only on the side of the moon nearest the earth, are said to be due to the light differing in various places under the influence of different angelic guides.

From the highest heavens to the lowest depths of the earth we find in Dante a faithful guide to the scientific ideas as well as to many popular prejudices of his time. Though the theory of spheres was during his lifetime defeated in France, an Italian may well be pardoned for not recognising this, particularly when we remember that even 200 years later two separate attempts were made in Italy to set up scientific theories of concentric spheres. To the student of the history of science it is a never-failing source of pleasure to find medieval cosmology so beautifully illuminated in the writings of the great Florentine poet.

The Natural History of Cultivated Plants.[1]

CLASSICAL plant-names like Μηδική πόα or *spina Arabica*, designed to indicate origin, do not always fulfil their object. Pliny's specific reference to *milium intra hos decem annos ex India in Italiam invectum* has not obviated debate as to the home and the identity of his plant. Many notices of ancient crops connote only local cultivation.

Renaissance naturalists connected their culti-

[1] "Sino-iranica. Chinese Contributions to the History of Civilization in Ancient Iran, with special reference to the History of Cultivated Plants and Products." By Berthold Laufer. (Field Museum of Natural History Publication 201: Anthropological Series, vol. xv., No. 3.) Pp. iv+445. (Chicago, 1919.)

vated plants with those mentioned by classical authors. In medieval "mysteries" a "maple" replaced συκόμορος. This tendency outlived the finding of America. When the Peruvian "papas" reached Artois from Rome, Clusius asked if here were ἀράχιδνα. Nor did scholars always agree. When the "sunflower" was first described in 1568 it was compared by Dodoens with the "coronary" Bellio, and by Cortuso with the "aromatic" Laserpitium.

The habit weakened as knowledge increased. But the history of cultivated plants was left to scholarship until R. Brown, in 1818, made it a branch of botanical geography. His "comparative view" of the esculent species reported by C. Smith and Lockhart during an expedition to the Zaïre dealt with the Guinea coast as scholars had treated the lands of the Mediterranean littoral. Necessity guided this action; Congo crops lie outside "letters." Alphonse de Candolle, whom Laufer calls "the father of the science of historical botany," explained in 1855 that the chapter on cultivated plants in his "Géographie botanique raisonnée" was partly inspired by Brown. In the "Origine des plantes cultivées" of 1883 the path Brown had opened up was again followed.

The results secured in 1855 by a botanist with historical instincts induced Hehn to ascertain in 1870 what scholarship guided by natural history tastes can accomplish. The limitations of "letters" were tacitly admitted in 1894, when Schrader, in his revision of Hehn's "Kulturpflanzen und Hausthiere in ihrem Uebergang aus Asien," sought aid from an eminent botanist. Thiselton-Dyer has shown, when elucidating complex subjects like ἄμπελος τῆς Ἴδης, that the successful student of cultivated plants should be both an accomplished botanist and a polished scholar. Collaboration occasionally yields mosaic results; regarding Engler's notes on the "vine," Laufer remarks that "it is not botany but historical research that is able to solve the problems connected with the history of our cultivated plants."

Hehn's "Kulturpflanzen" discusses the migration of Asiatic crops to Greece and Italy. Laufer's "Sino-iranica" presents Chinese evidence regarding ancient Iranian rural economy. The two purposes induce differences in outlook and treatment. The method of Laufer deviates from that of Schrader and Engler much as that of Brown departs from the methods of Gesner and Clusius.

Laufer employs history so effectively as almost to condone the acerbity of his criticism of others. He teaches us that sinologues enjoy advantages denied to classical scholars, since Chinese notices of useful plants lend themselves to historical treatment more readily than Hebrew, Greek, or Latin allusions. The Chinese, Laufer concedes, have shown thought and common sense when trying likely exotic crops. Their long series of encyclopædias, sometimes in several editions, afford approximate dates for many plant-introductions. The culture and influence of China increased gradually. If, like Rome, China suffered many invasions, she rarely succumbed to foes so destructive as the Vandal or so malignant as the Turk. Her civilisation remained little affected; the introduction of new plants never induced in China economic revolutions comparable with that experienced in Britain through the arrival of our staple root-crops.

Problems connected with the history of Chinese cultivated plants present familiar difficulties. Chinese records of introductions from Iran began two thousand years ago. The emperor Wu (140–87 B.C.) instructed General Chang-kien to fetch from Ferghana horses of the famed Iranian breed. Finding that these steeds throve on "lucerne" (*Medicago sativa*), Chang-kien carried home seed of this crop. As the plant had been established in Greece four hundred years earlier, we have some assurance regarding the home of Μηδικὴ πόα. With μηλέα Περσικὴ and μῆλον Ἀρμενιακόν matters are different; "peach" and "apricock" are Chinese plants, and the Iranian gift of "alfalfa" was but a payment on account. Later history affords instances equally instructive. The "Langka mirich" (= Ceylon pepper) of Hindu husbandry is the American "chillie" (*Capsicum frutescens*); to English denizens in India the American *Physalis peruviana* is the "Cape gooseberry."

With "medick" Chang-kien carried back the "grape-vine" (*Vitis vinifera*). Although Han travellers noticed Iranian addiction to wine-drinking, the art of wine-making was not acquired until the later T'ang period. It was received from the Turks, who in Han days lived in Mongolia, where the vine does not grow; when they invaded Turkestan the Turks learned the use of grapes and wine from their Iranian serfs.

Between the arrival of grape-growing (120 B.C.) and that of wine-making (640 A.D.) China obtained many western crops. Later Chinese naturalists, thinking backwards, state that, along with "alfalfa" and the "vine," Chang-kien brought from Iran chives, coriander, cucumber, sesame, and other vegetables. Some appear to credit to him the presence in China of any plant the name of which includes the attribute "hu." Historical research shows that while "hu" usually implies western origin, it affords no absolute criterion; even when a "hu" plant is really from the west, it need not be from Iran. The English misconception that our "potato" originated in Virginia and was introduced by Raleigh shows that the "process of retrospective thought" is not peculiar to China. Western misapprehension may exceed Oriental; our "potato" (*Solanum tuberosum*) is not the "patata" (*Ipomoea Batatas*).

The period 200–400 A.D. saw the establishment of trade relations with Po-se in Nan Hai. In A.D. 461 an embassy from Po-se in Iran reached Wei. After this event products of the southern Po-se were sometimes thought to be western ones, while Persian plants were occasionally regarded as Malayan. Europe has had the same experience. The navigators who first made American

landfalls believed they had reached India; those who stayed at home sometimes mistook West Indian for East Indian products. The "gallopavo" (*Meleagris gallopavo*) came to Europe in 1541. Its French popular names—"dindon" and "dinde"—leave open the question of origin; the English popular name "turkey-cock" indicates a belief that the bird came from the East. The French do not, however, claim greater perspicacity because of this; when "maize" (*Zea Mays*) first appeared they termed this cereal "blé de Turquie"; we, with fortuitous caution, used the non-committal name "Indian corn."

One undoubtedly western introduction attributed to Chang-kien is "hwan lan" (*Carthamus tinctorius*). The biography of the general and the annals of the Han contain nothing to this effect, and this introduction cannot antedate Tsin times (200–400 A.D.). This plant, which was unknown to classical writers, is the Arabic "kurtum"; its dried flowers, the Arabic "usfūr," came to medieval Europe under the Italian trade-names "asfiore" and "saffiore," our "safflower." The Chinese confused this product with "yü-kin," our "saffron," the dried stigmas of *Crocus sativus*; the two were colloquially termed "hun hwa" (=red flower). One of the uses of the dried flowers of "hwan lan" provided the plant with the alternative name "yen-chi," and thus led to its confusion with an indigenous "yen-chi" (*Basella rubra*), tinctorial in all its parts. Matters were further complicated by the existence of Mt. Yenchi and by the homophony of the Chinese name "yen-chi" (=cosmetic) with the Hiun-nu word "yen-chi" (=royal consort). It is scarcely surprising that Chinese disquisitions on "yen-chi" are more remarkable for their graceful style than for their historical accuracy.

The natural history of European economic products supplies problems equally complicated. The Greeks gave σκορπίουρον, the inflorescence of which is circinal, the alternative name ἡλιοτρόπιον because it flowers at the summer solstice. They distinguished two sorts of ἡλιοτρόπιον—τὸ μέγα, found in dry situations, and τὸ μικρόν, confined to damp places. No Greek text asserts that the blossoms of σκορπίουρον open only in bright sunshine or follow the sun from morn until eve. In spite of this some Latin authors regard Heliotropium as one of the "helioscopia," while others include it among the "solsequia." The Aramaic equivalent of ἡλιοτρόπιον is either "somar yauma" (=day turning) or "smar yauma" (=day-turned), so that in Syria the plant identified with that of the Greeks was one which the Romans, at least, would have included among their "solsequia." Arab naturalists identified "somar yauma" with the "tharanchul" of Andalusia. This Spanish "tornesol" (*Chrozophora tinctoria*) was in 1554 identified by Amatus Lusitanus with ἡλιοτρόπιον τὸ μέγα; in 1557 Clusius decided that it was ἡλιοτρόπιον τὸ μικρόν.

While our earliest records of *Chrozophora tinctoria* thus happen to be Iberian, Languedoc is the only region in which the economic product of the plant was ever systematically exploited. The Spanish name "tornesol" may therefore be, as we know the French name "tournesol" certainly is, only a local variant of the Provençal word "tornesola." Tournefort tells us that what we now know as *Chrozophora tinctoria* is the plant *ex qua paratur* Tournesol *gallorum* (=litmus) as contrasted with "Tournesol *lusitanorum*" (=cochineal). Pomet informs us that of the three distinct kinds of "French tournesol" known to commerce in the seventeenth century, only that termed "tournesol en drapeau" was prepared from this plant. The French term "tournesol," like the Chinese term "yen-chi," is therefore primarily the name of a commercial article colloquially transferred to the plant which yields it. The identification of "tornesol" with ἡλιοτρόπιον, propounded by two distinguished scholar-naturalists, teaches us that scholarship may prove as imperfect an instrument in solving problems connected with the history of cultivated plants and products as Laufer has found botany to be. Though both names are capable of conveying the same meaning, historical research shows that here "tournesol" involves a poetic comparison of the colour-change of an alterable dye with the hues of dawn and sunset, while ἡλιοτρόπιον supplies a prosaic intimation as to the season of the year at which a particular plant blossoms.

The difficulties which beset the conscientious study of European cultivated plants justify the remark made by T. Johnson in 1633 that "those that vulgarly impose names upon plants have little either judgment or knowledge of them." If the task of the historian of Chinese plants and products be less troublesome, this should lend support to the conclusion of Laufer in 1919 that "the Chinese were thinking, sensible and broad-minded people." However this may be, economic botanists of all nationalities will join to the penitence they feel for those shortcomings on their part which Laufer so unsparingly condemns a lively gratitude for the fund of information supplied by him in "Sino-iranica."

Obituary.

PROF. E. J. MILLS, F.R.S.

DR. EDMUND JAMES MILLS, formerly professor of technical chemistry in the West of Scotland Technical College, Glasgow, who died on April 21, was born in London on December 8, 1840. He received his early education at the Grammar School, Cheltenham, and later at the Royal School of Mines, London. The chemical instruction for students at the School of Mines was in those days given at the Royal College of Chemistry in Oxford Street, and there Mills worked during the later 'fifties, having as a fellow

student Herbert McLeod, afterwards professor of chemistry at the Coopers Hill College, with whom he formed a life-long friendship. At that time the only institution granting degrees in pure science was London University, and Mills utilised his education at the School of Mines with the intention of proceeding to such a degree at a later period. He obtained his Bachelor of Science degree in 1863 and the Doctorate in 1865, his name appearing in the list of graduates at a date intermediate between those of Prof. Crum Brown in 1862 and Sir Wm. Tilden in 1871. In 1861 he went as an assistant to Dr. John Stenhouse, having Tilden as one of his colleagues in that laboratory.

In 1862 Mills was appointed one of the demonstrators of chemistry in Glasgow University under Prof. Thomas Anderson, his chief duty being the conduct of tutorial classes in connection with the medical curriculum. This particular duty was by no means congenial to Mills, and his own perfect knowledge of his subject made him somewhat impatient with the backwardness of the majority of first-year medical students; with advanced students, however, and in the laboratory, he was a good teacher.

Anderson was then working on the products from the destructive distillation of coal and shale, and when not engaged in teaching duties Mills assisted him in that work. This brought him in contact with several people in Glasgow, notably John Young and others, who were interested in the oil industry, which at that time was attracting considerable attention in the Lanarkshire and Lothian districts. The friendships made in these early days may have had some influence in inducing Mills to return to Glasgow, as he did at a later date, but in 1865 he resigned his position as demonstrator at the university and returned to London.

In 1870 Mr. John Young founded the "Young Laboratory" in Anderson's College, Glasgow, a laboratory intended by him to be associated essentially with technical chemistry. The first superintendent of this laboratory was W. H. Perkin, sen. (1870–71), followed by G. Bischof (1871–75); they were succeeded by Mills in 1876.

About 1886 the "Young Laboratory" together with Anderson's College was incorporated in the Glasgow and West of Scotland Technical College, and became the "Young Chair of Technical Chemistry." This appointment Mills held until his resignation in 1891.

Papers recording Mills's original work are published in the proceedings of the Royal Societies of London and Edinburgh, the *Philosophical Magazine*, and the journals of the Chemical Society and the Society of Chemical Industry in London. They are numerous and of a varied nature. His first paper, given to the Royal Society in 1860, was on bromo- and chloro-phenyl, but his early work dealt more with questions on the general principles of chemistry and inorganic chemistry, such as isomerism, electric attraction, chemical mass, and chemical equivalents. In the Journal of the Chemical Society he published papers on aniline derivatives and nitrotoluene, potable waters, chemical repulsion, and melting points. From 1879–82 he published in four parts "Researches on Chemical Equivalents," "Investigations on the Action of Oxides on Salts," and in conjunction with Mr. Louis Campbell about 1879 "Researches on Dyeing." At a later period, on the foundation of the Society of Chemical Industry, he gave to that society papers on the quantitative estimation of oils and fats, viscosity determinations, and the oxidation of aniline. In the Proceedings of the Royal Society of Edinburgh he published researches on thermochemistry.

In the four small works which he published Mills did not confine himself to purely scientific subjects; in addition to two books, "Fuel and its Applications," in conjunction with E. J. Rowan, and "Destructive Distillation," he wrote a volume of poems, "My only Child," published in 1895, and "The Secret of Petrarch" in 1904.

After retiring from the professorship at the Glasgow and West of Scotland Technical College Mills returned to London, where he occupied himself with various pursuits, among them photography, which he had practised with considerable skill from early days. A certain deafness which overcame him during later years tended to increase a reserve of manner which Mills always possessed, but he continued until a short time ago to attend the meetings of the various societies to which he belonged, and was to be found regularly once a week at the Athenæum Club, where he met his more particular friends. He had a good knowledge not only of scientific, but also of general literature, and held some distinct views on religious questions; these, however, he never discussed.

Mills was elected a fellow of the Royal Society of London in 1874. He became a fellow of the Chemical Society in 1862, serving several times on the council, and as a vice-president from 1912 to 1915. He was an original member of the Society of Chemical Industry, and for a period president of the Glasgow and West of Scotland section of that society. He received the honorary degree of LL.D. from the University of Glasgow.

J. M. T.

DR. GEORGE FREDERICK WRIGHT, who died recently at the age of eighty-three years from heart failure following influenza, was, from 1881 to 1907, a professor in the Oberlin Theological Seminary, Ohio, and had been since 1884 the editor of a well-known theological publication, "Bibliotheca Sacra." His most important work, however, was done as a geologist, and his "Ice Age in North America," first published in 1889, remains a standard work on the subject. He wrote also on "The Glacial Boundary in Ohio, Indiana, and Kentucky," "Man and the Glacial Period," and "Greenland Ice-fields." At the invitation of the late Tsar of Russia Dr. Wright visited Siberia for

a geological study, the fruits of which appeared in 1902 in a two-volume work entitled "Asiatic Russia." The relations of science and religion were also discussed by him in several of his publications.

We regret to announce the death, on May 28, at sixty-four years of age, of Mr. R. E. Dennett, author of "At the Back of the Black Man's Mind," "Nigerian Studies," "West African Categories," and other works.

Notes.

Owing to the postponement of the sailing of the *Celtic*, on which he had booked his passage from America, Prof. Einstein is unable to lecture at King's College, London, until Monday, June 13, at 5.15 p.m. All the tickets which have been issued for June 9 will be available for that date.

Several changes have recently been made in the scientific staff of the Australian Museum, Sydney. Dr. C. Anderson, who has been mineralogist since 1901, succeeds the late Mr. R. Etheridge, jun., as director. Mr. A. Musgrave fills the vacancy caused by the death of Mr. W. J. Rainbow, entomologist, and Messrs. J. R. Kinghorn and E. le G. Troughton, second-class assistants, have been promoted to be first-class assistants in charge of reptiles, birds and amphibians, and mammals and skeletons respectively.

Mr. W. L. G. Joerg, of the scientific staff of the American Geographical Society of New York, and editor of its Research Series, left on May 21 on a six months' leave of absence for a trip to Europe on behalf of the society to study the present status and tendencies of geography in Europe and to establish closer relations with kindred workers and institutions. During his trip Mr. Joerg expects to visit most of the universities where modern scientific geography is represented. Communications to him may be addressed c/o Messrs. Brown, Shipley and Co., 123 Pall Mall, London, S.W.1.

At the anniversary meeting of the Linnean Society of London on May 24 the Linnean gold medal of the society, the highest award in its gift, was presented to Dr. Dukinfield H. Scott, and all who know the value and extent of his services to recent and fossil botany during the last forty years will agree that the award is thoroughly deserved, and some may be disposed to wonder why it was not bestowed earlier. The medal was instituted in 1888 on the occasion of the centenary of the foundation of the society, and is given in alternate years to a botanist and a zoologist who at the time of the award is not on the council. Dr. Scott's services as councillor, secretary, and president of the society have been almost continuous, so that the opportunities of making the gift have been very few until the present year.

The Mount Everest Expedition started from Darjeeling in two parties on May 18 and 19. The staff of the expedition consists of Col. Howard Bury, the leader, Mr. H. Raeburn, Dr. Kellas, Mr. G. L. Mallory, and Mr. G. H. Bullock, Alpine climbers; Mr. A. F. Wollaston, surgeon and naturalist; Dr. A. M. Heron, geologist; and Major H. T. Morshead and Capt. O. Wheeler, survey officers. Col. Bury's first dispatch to the *Times* contains particulars of the organisation and start. Major Morshead, with two assistants and fifty coolies, left Darjeeling in advance, going by the Teesta Valley to correct some of the Sikkim maps. He was to rejoin the main expedition on June 1 at Khamba Dzong. The principal transport of the expedition consists of 100 Chinese and Tibetan mules, with drivers drawn from hill tribes and accustomed to long marches. Forty Sherpa coolies, mostly from villages south or south-east of Everest, accompany the expedition. Several of them have been with Dr. Kellas on high climbs and are trained in ice-work. Mr. Wollaston is taking two Lepcha collectors and skinners to assist in biological work. The expedition has a complete photographic equipment, and every camera can be used for telephotographic work. Arrangements have been made for developing the plates and films on the spot. Col. Bury records with gratitude the help afforded by the Government of India, the Indian railways, and the Governor of Bengal (Lord Ronaldshay).

The secretary of the Institution of Electrical Engineers informs us that, in view of the continuance of the coal strike, the Scottish Committee has reluctantly decided to cancel the proposed summer meeting of the institution.

The autumn meeting of the Iron and Steel Institute will be held, by invitation of the Comité des Forges de France, in Paris, on Monday and Tuesday, September 5 and 6. At the conclusion of the meeting in Paris alternative visits have been arranged to works in Lorraine and in Normandy, and a party of the members has been invited to visit the Creusot works of MM. Schneider and Co.

Two notices of memorials to distinguished men of science appear in the *Revue scientifique* of May 14. The first refers to the monument erected to the memory of Wurtz the chemist at Strasbourg, which will be dedicated on July 5 next. The other notice deals with the centenary of Ampère's discoveries in electricity. Electrical engineers in France are taking steps to restore the tomb of the celebrated physicist in the cemetery of Montmartre.

The annual meeting of the British Science Guild will be held at the Goldsmiths' Hall on Wednesday, June 8, at 3 p.m. Lord Montagu of Beaulieu, president of the Guild, will present the annual report, and there will be addresses by the Very Rev. William R. Inge (Dean of St. Paul's) on "The Road to Ruin and the Way Out" and by Sir Richard A. S. Redmayne (chairman of the Imperial Mineral Resources Bureau) on "The Importance of Research in Promoting the Development of the Mineral Industries." Tickets may be obtained from the Secretary, British Science Guild, 6 John Street, Adelphi, W.C.2.

At the annual meeting of the Royal Society of Victoria, held on March 10 last, the following officers were elected:—*President:* Prof. Ewart. *Vice-Presidents:* Mr. F. Wisewould and Prof. Laby. *Hon. Treasurer:* Mr. W. A. Hartnell. *Hon. Librarian:* Mr. A. S. Kenyon. *Hon. Secretary:* Mr. J. A. Kershaw. *Members of Council:* Prof. Osborne, Dr. Summers, Dr. Baldwin, Mr. Dunn, Mr. Richardson, and Mr. Picken. In the annual report it was announced that the scheme for giving short popular lectures on subjects of general interest would be continued. At the ordinary meeting which followed Sir Baldwin Spencer contributed a paper entitled "Blood and Shade Divisions of Australian Tribes."

It is announced that Mr. Bridgeman, Secretary for Mines, has appointed an Advisory Committee for the Metalliferous Mining Industry, of which Sir Cecil Lindsay Budd is chairman. In addition to representatives of owners and of workers in mines and quarries, the following have also been appointed:—Mr. T. Falcon, Dr. F. H. Hatch, and Mr. F. Merricks, mining engineers; Mr. F. W. Harbord, metallurgist; Mr. T. C. F. Hall, Prof. H. Louis, and Dr. J. M. Maclaren, economic geologists; Mr. J. J. Burton, representing the iron and steel industry; and Sir Kenneth W. Goadby, representing medical science. Mr. F. C. Starling, of the Mines Department, will act as secretary to the Committee.

The London University College Hospital Ladies' Association was founded twenty years ago "to provide clothes for use in the wards, and also for necessitous patients on their convalescence or discharge from the hospital," and "to take up any other work in connection with the hospital which from time to time may commend itself to a general meeting of the association." It has been remarkably successful. There are now some eight hundred members; besides the central London body, there are ten local branches. The latest development is the establishment of the infant welfare department. Like all other London hospitals, University College Hospital is in financial difficulties. In order to help, the Ladies' Association has arranged to hold a sale on Wednesday, June 8, from 11.30 a.m. to 7 p.m. at Someries House, Regent's Park. Her Highness Princess Helena Victoria has graciously consented to open the sale. The things offered for sale will be of a varied nature, including fruit and other farm and garden produce. There will also be some special features, such as an antique stall and a second-hand book stall which may interest our readers.

On April 2 last, the Governor-General of New Zealand, Lord Jellicoe, formally opened the Cawthron Institute in Nelson, South Island. The institution was founded under the terms of the will of the late Thomas Cawthron (Nature, January 1, 1920, p. 442) to provide a place for teaching and carrying out scientific research relating to the industries of Nelson and of the Dominion. Lord Jellicoe paid eloquent tribute to the great public generosity of the late Mr. Cawthron, and then spoke of the importance of scientific research. For an agricultural community to achieve success the agriculturists must co-operate with men of science. The work undertaken in the new institute will deal largely with problems of agriculture, fruit-growing, etc., and should therefore exert great influence on the prosperity of the whole of the Dominion. The Bishop of Nelson, who is chairman of the trustees, also addressed the gathering, and made particular mention of the library of scientific books belonging to the institute, which it was hoped, when completed, would be the best in Australasia. Prof. Easterfield, director of the Cawthron Institute, gave a brief outline of the many lines of research now occupying the attention of the staff; soil surveys, experiments with fertilisers and cover-crops, fire-blight, the deterioration of trout, fruit pests, and the utilisation of flax-waste were among the problems mentioned.

The *Geographical Review*, issued by the American Geographical Society of New York "upon the adoption of a programme of intensive research," has in the present year ceased to become a monthly periodical; in future it will be issued as a quarterly. We welcome this change of form, as it gives an opportunity for more detailed papers on the subjects to which this valuable publication is devoted. In its new form it contains several important articles, one of the more interesting being an elaborate essay on "The Evolution and Distribution of Race, Culture, and Language" by Dr. Griffith Taylor, of the University of Sydney. This article raises questions which it is impossible to criticise in detail. The author proposes to show that "many current opinions with regard to the mixing of nations are not supported by ethnology." On the problem of the half-caste he is disposed to think that "in many cases the ethnic deterioration is too slight to be important, and that racial antipathy rather than racial degeneration is largely to blame for the troubles of the Eurasians. As regards the Alpine, Mongolian, and most Amerind and Polynesian peoples, the future seems to me to be most promising. It is our diseases and our vices, especially the use of alcohol, which constitute the so-called 'overpowering effect of the white civilisation' upon the uncivilised nations."

A paragraph in Nature of July 1, 1920, p. 558, referred to a report of the Smithsonian Institution in which Mr. C. M. Hoy made some comments on the extermination of Australian native fauna. We quoted some of Mr. Hoy's remarks, concluding with the words:—"There are very few game laws in Australia, and no one gives any attention to the ones that are in order." The Minister of Industry, South Australia, afterwards wrote through his secretary objecting to Mr. Hoy's statement, and his letter was published in Nature of November 18, 1920, p. 377. Mr. Hoy in a communication dated from Sydney, New South Wales, on March 12, claims that his original statement was correct, and adds:—"Everywhere I went in South Australia I found flagrant disregard of the Animals and Birds (Protection) Act, not only in the 'out-back areas,' but within a few miles of Adelaide itself." As Mr. Hoy's notes were originally published by the Smithsonian Institution, and we merely quoted from them, his letter was submitted to the institution, the acting secretary of which

now informs us under date May 7 that "while Mr. Hoy is collecting specimens in Australia for the Smithsonian Institution, he is in no sense an officer of the institution." A letter has therefore been sent by the institution to the Minister of Industry, South Australia, expressing regret that anything written by Mr. Hoy should have led to misunderstanding, and gratefully acknowledging "the kind assistance given Mr. Hoy both by the authorities and private citizens in the various parts of Australia which he has visited."

Sir Hercules Read in his presidential address to the Society of Antiquaries (*Antiq. Journal*, vol. i., pp. 167–82, July, 1921) avails himself of his approaching freedom to deliver some home-truths. "The contents of a museum take precedence of the building that contains them." Disregard of this principle and of the views of the museum officers by two distinguished architects has made the Victoria and Albert Museum and the northern annex to the British Museum "deplorable and costly mistakes." (Sir Hercules says this would not occur in the case of a laboratory. Well, there is such a building recently erected to the plans of one of these architects in which the best light is given to passages and the windows of the work-rooms are obscured by useless balustrades and overhanging arches.) The Government has allotted to London University a site that will soon be required by the expanding British Museum. Congestion may be in part relieved by removing objects from exhibition into store; but this is only to postpone the inevitable removal of either the museum collections or the national library to another site. Lastly, the recent trouble with Scotland over a battered gravestone leads Sir Hercules to condemn the stringent embargo which several countries have laid on the export of all—even their most trivial—antiquities. At any rate, we shall all agree that for the British Isles, if not for the British Empire, the British Museum should be the centre where a complete representation of all products of Nature and art can be seen. We need, instead of competition, intelligent co-operation between the various museums.

The mode in which the narrow-mouthed lamprey (*Geotria stenostoma*, Ogilby) ascends waterfalls is described by Mr. D. A. Herbert in the Journal of the Royal Society of Western Australia (vol. vi., part i., 1920). The animal can obtain hold only on a wet surface, and the cutting off of the water by a hand placed above the fish causes it at once to drop back into the pool. Two excellent photographs are given of the toilsome climb.

In a second important paper on the structure of the Andes (Quart. Journ. Geol. Soc., vol. lxxvi., p. 1, 1920) Mr. J. A. Douglas points out that the Alpine type of overfolding cannot be traced in the Andean Cordilleras, and that the chain is due to vertical uplift between two ancient resistant masses which from time to time have compressed a series of transgressive deposits between them. The author continues the fine series of photographic plates that characterised his previous paper published in 1914.

Dr. C. D. Walcott, secretary of the Smithsonian Institution, has informed the Rev. T. R. R. Stebbing that since the appearance of Raymond's memoir on the trilobite he has reviewed his own trilobite sections, and also cut a number of additional sections, one of which, fortunately, cuts across the exopodite so as to show its structure and the relations of the fringe of filaments to the spiral arm. Other sections indicate that the ventral limb was formed of a coxopodite, endopodite, and exopodite, and, in addition, a short, flat epipodite with numerous long, strong filaments. Dr. Walcott has also succeeded in securing photographs of the epipodites of Neolenus, which illustrate the difference between them and the exopodite.

An interesting paper by Mr. Leslie Scott on "Agricultural Co-operation" appeared in the April issue of the *Fortnightly Review*. In the author's opinion, the farming community—especially the class of small farmers—exerts a considerable stabilising influence in the nation, and it is therefore highly desirable that this class should be maintained. Farmers have to face foreign competition, and they have to stimulate home demand; the best way to do these two things is to cut down wherever possible the expenses incurred in distribution and in the purchase of feeding-stuffs, etc. "Factory" farms reduce production costs, but they also eliminate the small farmer, for the factory farm consists of 10,000–20,000 acres farmed by a manager appointed by some company. Agricultural co-operation seems to be the only method by which economic production can be attained and the small farmer preserved at the same time. A great deal is done by such co-operation in Denmark, and there are a few agricultural societies doing good work in this country, but there is a great need for union among these different societies. They are now being joined up in the Agricultural Wholesale Society, and as soon as the farmers put implicit trust in their own societies and the societies place equal trust in the central body, then the wholesale society—provided that it is adequately capitalised—will be able to make practically its own terms in the markets both of this country and of the world.

The Douglas fir, *Pseudotsuga Douglasii*, the most valuable conifer in western North America, is now planted extensively by foresters in this country, as it produces a large volume of timber in a short period of years. Until recently this tree enjoyed practical immunity from both insect attack and fungus disease, but this happy state no longer exists, and it is necessary now to sound a warning that unless preventive measures are taken, great disaster may befall plantations of this species. Such has happened in the case of the white pine, *Pinus strobus*, an American tree that can no longer be commercially planted in Europe on account of its liability to succumb to the deadly fungus *Peridermium strobi*. The Douglas fir is becoming infested in the South of England with a woolly aphis, *Chermes Cooleyi*, which was first noticed in 1914 in the New Forest. Its spread since then has been alarmingly rapid, and isolated attacks were noticed last summer in Peeblesshire. It is distressing to hear also of a fungus which has been

doing considerable damage of late years to young plantations of Douglas fir in many parts of Scotland. This either kills the leading shoot a few inches below the tip or causes the death of the whole tree by attacking the outer tissues completely round the stem at a little distance above ground-level. In both cases there is a sudden decrease in diameter in passing from the healthy to the diseased portion of the stem, accompanied by much exudation of resin. This fungus is described as a new species, *Phomopsis pseudotsugae*, by Dr. Malcolm Wilson in the Transactions of the Royal Scottish Arboricultural Society (vol. xxxiv., part ii., pp. 145–49, plates iv.–v.) published in November last. Early recognition of the disease and burning of affected trees are the measures recommended for stamping out this pest, which has been known to kill half the trees in a young plantation.

A LENGTHY paper on "The Perishing of Paper in Indian Libraries" forms part vii., vol. iii., of the Journal of the Indian Institute of Science. The investigation was undertaken at the Institute of Science on behalf of the Government of India by Mr. J. J. Sudborough and Miss M. M. Mehta. "Perishing" is defined as a brittleness which is so marked that folding the paper once or twice will cause it to break along the fold, and it is observed in many of the books in record offices and libraries. The conclusions which the investigators have arrived at as the result of an examination of numerous libraries in India do not differ greatly from the report of the Committee on the Deterioration of Paper in Europe published in the Journal of the Royal Society of Arts for 1898 (No. 46), or from the report of a similar committee in America which appeared as Report No. 89, Pub. 1909, U.S. Department of Agriculture. Chemical perishing, as distinct from the destruction caused by micro-organisms, was investigated, and the conclusion arrived at is that the former type of perishing, which is by far the commoner, is due to hydrolysis of the cellulose molecules of the paper and their later decomposition into simple substances rather than to a process of oxidation. The type of paper found to be most resistant in India is a rag-paper the fibres of which have not been weakened in the process of manufacture. Treatment which has been found to damage the fibre is prolonged digestion with alkali, over-bleaching, non-removal of the last trace of bleach by antichlor, and imperfect washing that leaves traces of acid in the paper, while rosin and filling material should not exceed a small fixed percentage. It is recommended that all books and documents of permanent value should be removed to libraries in hill stations with temperate climates or placed in special buildings in which complete air control can be maintained.

SEVERAL distinctive features are embodied in a new model radioscopic couch by Messrs. Newton and Wright, Ltd. The tube-box, which is fitted with a holder to take a gas tube or Coolidge tube, is covered by sheet-lead and mounted upon steel rails, free movement being ensured by ball bearings The diaphragm is of the rectangular type, and is operated by levers attached to a control arm; this latter projects horizontally from the tube-box, and is supported by one of two metal uprights which hold the protective apron in position. A further feature of interest is that these uprights allow the tube-carriage to be shifted longitudinally by the operator's knees, which should at times be found a great convenience. Protective devices figure conspicuously in this new model.

REMARKABLE developments have taken place in the use of water-power in many parts of the world during recent years, with which English engineers who have not time to consult foreign publications are unfamiliar, and in which English manufacturers have taken but little interest. The possibilities of development in this country and in other parts of the Empire of the sources of water-power are awakening an interest in the subject, and the proposed issue by Messrs. Henry Frowde, and Hodder and Stoughton, under the editorship of Prof. S. M. Dixon, of a quarterly *Journal of Hydraulics*, at an annual subscription of 31*s*. 6*d*., each number of which will be self-contained and will make available in a convenient form details of the most recent developments of hydraulic engineering, should prove of interest and value to many engineers. A sufficient number of guaranteed subscribers is required before the first issue.

DR. ARNE WESTGREN has carried out some Röntgen spectrographic investigations of iron and steel in the University of Lund, Sweden, and presented his results at the May meeting of the Iron and Steel Institute. He has verified Hull's result that iron at ordinary temperatures (α iron) has a cube-centred cubic lattice structure, the edge of the unit cube being 2·87 Å. He finds that between 800° and 830° C.—that is, within the so-called β-iron range—the atoms are oriented in exactly the same way as in α iron, the edge of the unit cube being 2·92 Å. If allotrophy is accepted as being the same as polymorphy for solid crystalline bodies, this means that β iron cannot be considered as a separate modification. On the other hand, both in pure iron and in austenite at 1000° C.—that is, in the γ range—the crystals have face-centred cubic lattices, the edge of the unit cube being 3·61 Å. Consequently, this is characteristic of γ iron, and a fundamental crystallographic difference exists between α and γ iron. In martensite, the constituent of hardened carbon tool-steel, Dr. Westgren has found that the iron is in the α form. This is also the case in high-speed tool-steel hardened at 1275° C. The investigations are being continued, and will be extended to include complex phases in steel and other alloys. Spectrograms of cementite show that its crystal structure is related to that of γ iron, a fact which explains the mutual solubility of these phases.

LISTS Nos. 182 and 183 of the Cambridge and Paul Instrument Co., Ltd., give particulars respectively of the Cambridge microtomes and the Cambridge recording clinical thermometers. The firm now manufactures three types of microtomes. The universal microtome, on a circular cast-iron base of 250 mm. diameter, is constructed on similar principles to the Cambridge "rocker," but has a wider range of application; it cuts sections of 0·001 to 0·035 mm. in thickness from objects up to about 18 by 20 mm. in dia-

meter embedded in paraffin or celloidin. Since the object moves in a horizontal plane along the arc of a circle, it has the advantage that the sections are flat. The rocking microtome is similar in general construction to the instruments manufactured in previous years, but with improvements in details; it will cut sections 0·002 to 0·024 mm. in thickness from paraffin-embedded objects up to about 12 by 20 mm. in diameter. The freezing microtome has been specially designed for use in operation work. The thermometers, which give continuous automatic temperature records extending over a considerable period, are of the electrical resistance type, and consist essentially of a bulb containing a coil of platinum wire joined by connecting wires to a recorder. The record consists of a series of dots on the chart-paper, impressed every minute or half-minute as is desired.

Two correspondents have forwarded further suggestions for picture-hanging wire in reply to the letter under that title published in NATURE of May 19 last. The first relates to the use of single-strand enamelled phosphor-bronze wire of No. 18 B.W.G. This has been found satisfactory for pictures of moderate weight. The other method, similar to that described in NATURE of May 26, p. 395, is to use ordinary copper bell wire 0·055 in. to 0·02 in. in diameter. Pictures varying in weight from 1 lb. to 50 lb., using two wires for the heavier pictures, have been hung successfully with it. The need for straightening the wire carefully is emphasised in both letters, and the advisability of avoiding sharp bends at the edges of hooks is mentioned.

MESSRS. W. HEFFER AND SONS, LTD., Cambridge, have in the press a work, to be published in three parts, entitled "Dates and Date Cultivation in the 'Iraq," by V. H. W. Dowson, of the Agricultural Directorate of Mesopotamia. The three sections comprising the work will deal respectively with the cultivation of Basra date palms and the marketing of the fruit; statistics and details of the experiments from which the average yield of date gardens per acre is adduced; and the varieties of date palms found at Basra. Part iii., which will be illustrated, is promised for the coming autumn.

Our Astronomical Column.

PONS-WINNECKE'S COMET.—Mr. W. F. Denning writes:—"On May 28 this comet was conspicuously visible in a field-glass. The comet is at present situated in the Milky Way amongst the stars of Cygnus, and is moving to the south-east at the rate of about $3\frac{1}{2}°$ per day. It is increasing in apparent brightness, and may possibly come within naked-eye vision at the middle of June. The latest observations prove that the comet is farther from the earth than was expected, and that at perihelion it will be about 2,000,000 miles outside the terrestrial orbit. Perturbations by Jupiter in 1918 have altered the cometary path and lengthened the period of revolution. There may be a meteor shower on the nights from June 27 to 30, but the conditions are such that the display may not be a very brilliant one. Observations should be carefully made at the period mentioned, and it is fortunate that the evening sky will be free from moonlight."

SPECULATIONS ON THE FORMATION OF SPIRAL NEBULÆ.—M. Alex. Véronnet contributes an article on this subject to the *Comptes rendus* of the Paris Academy of Sciences for April 18. He examines the effect that would result from the impact of the two components of a binary system. He shows that the energy produced by friction at their surfaces is the most important factor, and that a mass equal to that of Jupiter might produce by impact with the sun a temporary increase of light amounting to twelve magnitudes. Radiation-pressure would then expel the heated particles with high speeds, and the revolutionary movement of the stars would give a spiral formation to the scattered particles. The author seeks thus to explain the phenomena both of novæ and of spiral nebulæ. He concludes that the latter would undergo a rapid evolutionary transformation (in the course of a few centuries). It would seem, however, that the larger spiral nebulæ are on too grand a scale to be the product of the impact of a mere pair of stars. The hypothesis is, however, worth considering in relation to such nebulæ as that which was revealed round Nova Persei by the light of the outburst, and Hubble's variable nebula in Monoceros.

M. Véronnet quotes the results obtained by Mr. Van Maanen, from photographs taken at intervals of several years, on the movements going on in certain nebulæ. These showed an outward tendency, agreeing with M. Véronnet's conclusions.

The nebula round Nova Persei had evidently been present, though unseen, before the outburst, and the suggestion had already been made that it might be the product of a former impact of the same two bodies that caused the outburst of 1901.

THE COMPANION OF α HERCULIS.—In the course of a paper on "Seven Spectroscopic Binaries" (*Astrophysical Journal*, April) Mr. R. F. Sanford announces that the fainter star of this well-known pair is a spectroscopic binary with a period of 51·6 days, only one spectrum being visible. He further announces that the radial velocity of the centre of gravity is −37·2 km./sec., whereas that of the principal star of the visual pair is −32·2 km./sec. Mr. Sanford concludes from this that the visual pair is only an optical one, the components not being physically connected. The following considerations, however, appear to show that this conclusion is unwarranted:—

The chance of two unconnected stars of magnitudes 3·5 and 5·5 being within 5″ of each other and having the same proper motion of 3″ per century in the same direction is so small as to be absolutely negligible. Moreover, the assumption of physical connection does not involve an unreasonable value of the masses. The spectroscopic parallax of component B is 0·018″ and the angular separation 4·7″, or 260 astronomical units (if unforeshortened); a joint mass equal to that of the sun would give a relative velocity in a circular orbit of 1·84 km./sec. The actual relative velocity is 5·0 in the line of sight and 1·6 at right angles, the position angle having altered by 6° in eighty years. The combined velocity is 5·25, giving a joint mass of $(5{\cdot}25/1{\cdot}84)^2$, or 8·14 times that of the sun. We know of many greater stellar masses; for example, in a paper by Herr P. Hügeler in *Astr. Nach.*, No. 5098, the masses of the components of u Herculis are calculated to be 7·43 and 2·84 in terms of the sun.

Administration of Scientific Work.

LORD HALDANE presided at a meeting of the National Union of Scientific Workers held at University College, London, on May 30, at which Prof. L. Bairstow gave an address on "The Administration of Scientific Work."

Lord Haldane said that the occasion was most interesting to him, as he was presiding over a meeting of what bore a resemblance to a trade union. We were apt to forget that an organisation must have another purpose than merely the promotion of the interest of the individuals who belong to it. An organisation sometimes helped to keep standards high and shield the right, and that was one of the dominant aims of the National Union of Scientific Workers. The problem of how science and administration were to be related was a difficult one. Scientific men were often impatient of administration and the Treasury, but though these institutions hindered imaginative enterprise, he was not altogether sure the case was against them. Considering the expenditure now afforded on scientific research, we had little cause to lament the present period. The highest science did not allow itself to be organised, but it did not follow that for this reason there was to be no limit placed on expenditure.

Prof. Bairstow avowed as his ideal world one which was so administered as to ensure remuneration adequate for work, and thus secure in great abundance that desirable product, the work of the worker. Though most people would subscribe to that idea, it was the failure to work it out effectively that was responsible for most of our troubles. We lived in an age of "brain-waves," of disproportionate rewards for accidental discoveries, and the union was strongly opposed to such rewards. Scientific research was the foundation of progress; stop it, and industry would stagnate on the scientific side. Scientific ability should not be used up in applied research, which under existing conditions afforded more opportunities to the young and ambitious scientific worker than research at a university. University workers were under the perpetual shadow of financial anxieties, and could not, therefore, give their best work to instruction and research. The root of the problem was the resistance of the administrator to the idea of co-operation with the worker. Prof. Bairstow illustrated this point by reference to the programme for aeroplane construction prescribed in 1917 for the following year. Specifications for a number of types of machine were laid down without reference to the assistance of the technical *personnel* of the Air Board or of the aeronautical industry, with the result that manufacturers were unable to accept contracts on the basis of the specifications. The effect of this action was to denude the Department of its best technical men the moment the armistice was signed.

In proposing a vote of thanks to Prof. Bairstow, Sir Frank Baines congratulated him on the moderation he had shown, though he was convinced that under his reserve there was evidence of indignation against the position in which the scientific worker was placed to-day.

Dr. George Senter, in thanking Lord Haldane, ventured the opinion that only a short time would elapse before the whole nation would realise what scientific men realised already, the great value of the work he had done as the head of two Government Departments—work that was carried out in the true scientific spirit.

New Technical Applications of an Electrostatic Principle.

ON May 26 Messrs. A. Johnsen and K. Rahbek, two Danish engineers, gave a most interesting demonstration to the Institution of Electrical Engineers of new electrostatic microphones, telegraphic relays, etc., based on a little-known electrical phenomenon. If a smooth plate of brass is placed on a smoothly polished slab of lithographic stone about 1 in. in thickness resting on a conductor, and a potential difference of 400 volts is applied between the metal plate and the conductor, a strong attraction will be developed between the plate and the stone. Messrs. Johnsen and Rahbek demonstrated that the attraction between a metal disc about 2 in. in diameter and the stone was greater than 1 kg., although the current flowing was only a few micro-amperes. Provided the disc is in contact with the stone and the microscopic current is flowing, it lifts the stone as a magnet lifts its keeper. But when the current is broken the attractive force vanishes. The stone is a semi-conductor, but the voltage drop across the stone is very small compared with the voltage drop due to the resistance of the film between the brass plate and the stone. The force, therefore, is due to electrostatic attraction, which for a plate condenser varies inversely as the square of the distance between the plates.

This phenomenon has been utilised by the authors in the development of apparatus which will prove of great value in electrotechnics. Lithographic stone, slate, limestone, agate, flint, and many other semi-conductors can be used to show the electrostatic attraction. If the semi-conductor be rotating and a metal band slides on it, the friction between them will vary largely with the slightest variation of the microscopic current between them. As very appreciable mechanical forces are called into play, it is possible to utilise them in technical applications. In radio-telegraphy, for instance, it is useful as a thermionic recorder, the current from the ordinary small valves being amply sufficient to operate it at a speed of several hundred words per minute provided that at least 100 volts be used for the valves. Excellent records obtained in Copenhagen were shown of the messages sent out from the Eiffel Tower. As the recorder is free from self-induction, there is no practical limit to the speed at which records can be taken. If the metal band be connected to a sound-producing diaphragm and telephonic currents pass between it and the rotating semi-conductor, an extraordinarily loud-speaking telephone can be obtained. Using the body of a violin as the diaphragm, it was shown that the sounds produced by a violin played at a distance could be perfectly reproduced in the lecture theatre. Ordinary speech also was excellently reproduced and could be heard all over the room.

In connection with their inventions it is interesting to recall that Edison's first loud-speaking telephone depended for its action on electrostatic attraction. A chalk cylinder was rotated and a metallic spring pressed against it, a current passing between them. Sir William Barrett described this instrument to the Royal Dublin Society on January 19, 1880, and a summary of his lecture was given in NATURE (March 18, 1880, vol. xxi., p. 483). The electrostatic theory, however, was not then favoured. In 1905 Mr. Rollo Appleyard in a paper to the Physical Society described the adhesion which occurs between a metal plate and a dielectric when a very minute current passes between them. Electricians also have attributed to the effects of electrostatic attraction the alteration in the insulation resistance of paper condensers as the voltage varies.

Dalton and Atomic Symbols.

IN an article in the *Moniteur Scientifique Quesneville* Prof. Maurice Delacre, stimulated by a passage in "The Life and Work of Gerhardt" by E. Grimaux, severely criticises the attitude which was taken up by Berzelius in his celebrated "Essai sur la théorie des proportions chimiques" (Paris, 1819) towards the work of Dalton. The chief ground of the criticism is that in this work, the original of which appeared in Swedish in 1818, Berzelius describes his well-known system of chemical symbols without making any mention of the fact that Dalton had more than ten years previously introduced true atomic symbols and used them for the construction of formulæ. The passage in the "Essai" of Berzelius reads as though he himself had been the first to conceive this happy idea, and has thus given rise to the erroneous view entertained by some writers on the history of chemistry that Berzelius invented atomic symbols, whereas the credit is entirely due to Dalton.

Berzelius further, in the opinion of the author, exaggerated the importance of the work of Wenzel and Richter and minimised that of Dalton in connection with the discovery of the laws of chemical combination, whereas, in fact, these laws were clearly enunciated only after Dalton's ideas about atoms had become known. Prof. Delacre propounds the thesis that there is only one chemical law of weight, and this he proposes to call the "law of the symbol," regarding the laws of definite and multiple proportions as corollaries of this fundamental law.

There is here some confusion between experience and theory, and we do not regard this suggestion as judicious. It is, of course, true that Dalton's atomic theory has as necessary corollaries the laws of chemical combination, but the theory rests ultimately on the observations by which these laws were established, and to these observations it is undeniable that Wenzel and Richter made important contributions. In the matter of atomic symbols Dalton has, in this country at least and in most of the historical works with which we are acquainted, received full credit, and it is with surprise that we learn that some writers still erroneously attribute this important advance to Berzelius.

The Melbourne Meeting of the Australasian Association.[1]

II.

Abstracts of Presidential Addresses to Sections.

SECTION A (*Astronomy, Mathematics, and Physics*).—Prof. H. J. Priestley, of the University of Queensland, in his presidential address traced the development of the theory of relativity. In discussing the Einstein spectral-line effect, he pointed out that the usual treatment of the question involves the assumption that the time-period of the source is transmitted by the radiation to the observer. He gave reasons for making the alternative assumption that the Einstein interval *ds* is transmitted by the radiation, in which case the displacement of spectral lines should arise from a change in the field of the observer, not in that of the source. To meet the possible objection that the usual method of establishing the deviation of light in a gravitational field appears to imply an underlying constant time-period in the radiation, Prof. Priestley showed that the light path in a gravitational field could be found by a method which made no appeal to pre-relativity physics, and implied, therefore, no assumption as to the constancy of the time-period.

Section B (*Chemistry*).—Prof. N. T. M. Willsmore, in the course of his presidential address, referred to the indispensable work of British chemists during the war, stating that in the manufacture of explosives and in devising counter-measures against the enemy the chemist held the key to the position. Chemists were needed to deal with poison gas, to supervise water-supply, for the manufacture and use of artificial fog in the Navy, in the munition factories, and in numerous other spheres. In future wars chemistry would play an even greater part, and in the United States the Chemical Warfare Service had been organised as an independent branch of the Army. Prof. Willsmore then indicated the immense amount of work done by the chemists in the explosives and other factories in Great Britain.

Section C (*Geology and Mineralogy*).—"Recent Advances in our Knowledge of New Zealand Geology" was the title of the presidential address delivered by Prof. W. Noel Benson. The geological history of New Zealand was divided into three major periods, the oldest closing about Carboniferous times, the second in Lower Cretaceous times, and the third at the end of the Pliocene period. Comparative tables showing the classification of the strata in each period by many students of New Zealand geology illustrate the gradual evolution of the knowledge of New Zealand stratigraphy. It has been customary to consider the complex of gneisses and associated rocks in "Fiordland" as of Cambrian or pre-Cambrian age, but recent work by various investigators tends to show that this view is incorrect. Prof. Benson concludes that while some of the crystalline complex may be pre-Ordovician, the bulk of it is probably post-Ordovician, and some may be even of Mesozoic age. These rocks have been invaded by more or less gneissic plutonic rocks during a period of orogeny, followed either immediately or at a later orogenic period by massive plutonic intrusions. To the second period belong the "Maitai" (? Permian) and the "Hokonui" (Trias-Jurassic) systems. The relationship between the Hokonui series and the underlying Maitai series was discussed at length, and the conclusion reached that there is little evidence of a great unconformity, though crust-warping probably occurred. An interesting problem of New Zealand geology, the origin of the Otago schists, was also discussed. These rocks have been assigned to ages ranging from pre-Cambrian to Mesozoic. Prof. Benson suggested that they occurred as a series of sheet-folds, occasionally upturned and crushed, and composed for the most part of the metamorphic equivalents of Middle and Lower Triassic and Permian formations. The varying views as to periods of orogeny and plutonic intrusion and the general direction of folding were described and a new interpretation of the facts was suggested. Following the Hokonui orogenic movements, marine deposits were laid down, commencing with Middle Cretaceous and extending into Upper Pliocene beds. The diverse views of the relationship between these series were discussed and a complete bibliography of the literature was given. It was pointed out that during the deposition of these marine beds only in Otago is there evidence of a persistent land surface. The affinities of the fossil

[1] Continued from p. 410.

faunas and floras of New Zealand were then outlined and various views as to the existence of a land connection between New Zealand, Antarctica, Australia, and Malaysia were reviewed. The latter portion of the address dealt with igneous rocks from Cretaceous to more recent times and with the later orogenic movements and resultant physiographic features. In conclusion, Prof. Benson appealed for detailed investigations in New Zealand in all branches of geology.

Section D (*Biology*).—The president, Prof. A. J. Ewart, gave a summary of the work done in botany and geology during the war period, and pointed out that, large as it was, these sciences were not stimulated by war activity, as chemistry and physics were. With the increased productive activity now necessary to replace the waste of war, botany and geology would resume their original importance as the primary sciences connected with productive activity.

Section E (*Geography and History*).—"Geographical Problems of To-day and the Status of Geography in Science" was the subject of the presidential address delivered by Sir Douglas Mawson. He referred to the geographical changes brought about by the war. The war had put a temporary brake on geographic exploration and curtailed the study of geography at the universities, but it had been a great stimulus to map-making. Three recent events, each of which marked a stage in the geographical development of Australia, were the completion of the transcontinental railway, the first aerial link with Europe established by Sir Ross Smith, and the founding of an associate professorship in geography at Sydney University. It was gratifying to record the beginning of what might confidently be expected to be a more general recognition of geography as a definite science subject in Australasian universities. Such a movement would be greatly advanced by the existence of a vigorous geographical organisation in Australia. There was an unrivalled field for geographical inquiry in the Commonwealth, and under the stimulus of modern movement great things were to be expected. Even the coast-line of Australia was as yet only partly charted. Now that the Commonwealth had instituted its own Navy it had need also of organising an efficient hydrographic service to cope with this undertaking. In this a beginning had already been made, but to do justice to the Melanesian dependencies as well an extensive and well-founded organisation was needed. Fields for general exploration included parts of central and north-western Australia, Papua, and those territories for which Australia held mandates. Good geographical research could also be undertaken anywhere in Australia if investigators selected a definite area and worked it out in complete geographical detail.

Section F (*Ethnology and Anthropology*).—"Anthropology and the Government of Subject Races" was the title of the presidential address delivered by Mr. Justice Murray, Lieutenant-Governor of Papua. He pointed out that there were two methods of governing native races: (1) to abolish all native customs and institutions and introduce European substitutes, or (2) to use as an instrument of good government such customs as appeared to be useful, or even harmless. Anthropology was of service only with the latter, the "indirect" method, favoured by the British. Among savage races the different departments of thought and action were not clearly distinguished, as with us, and this must be borne in mind when dealing with them. Anthropology had so far not played an important part in administration. In the future, however, it was likely to become of the greatest help, either through the appointment of specialists or by encouraging the study among Government officers. The capacity of "thinking black or brown" required more sympathy and insight than the average man possessed, but it was very necessary, for there was always danger that natives would misconstrue some policy. The best remedy was the study of anthropology. It was partly to encourage this study among officers, and partly to assist the Government more directly, that arrangements were being made for the appointment of an officer as Government Anthropologist.

Section G (*Social and Statistical Science*).—Mr. G. H. Knibbs, Commonwealth Statistician, selected as the subject of his presidential address "World and Empire Development." Mr. Knibbs pointed out that the huge destruction of material wealth and the world-wide dislocation of economic relations had accentuated the importance of obtaining systematised statistics. This was recognised in the endeavour to establish a statistical branch for the League of Nations, as well as the International Institute of Statistics at The Hague and the International Institute of Agriculture at Rome. The rate of growth in the population of the white races which had characterised the last century was about 1 per cent. per annum, so that the population doubled itself in slightly under seventy years. Such a rate could not possibly continue, because of the limitations of food- and water-supply. Various materials, especially aluminium, were also being used up at a rate which was increasing more rapidly even than the population. Statesmen must perforce take account in the widest possible way of the rates of development and of exhaustion of supplies. The British Empire Trade Commission which visited Australia in 1913 realised that British business interests necessitated Imperial statistics, and it recommended a conference of the statisticians of the Empire. The conference recommended the establishment of a British Empire Bureau of Statistics, incorporated by Royal charter, the Prime Minister of the United Kingdom to be president in his capacity as *ex-officio* president of the Imperial Conference. The general aim was to facilitate the analysis of the drift of the past and to forecast the future position of the Empire. The falling-off of productive efficiency in Australia was an ominous fact for a young nation possessed of a valuable heritage and needing population for its development.

Section H (*Engineering and Architecture*).—In his presidential address on "The Present System of Education of Engineers and Architects" Mr. M. E. Kernot found grave faults in the education and training of men who were entering the profession. Experience with men who commenced at practical work and got into a groove often showed how much they might have done had they had the advantage of university training. With the system of articles results were also very variable; pupils who had completed their training in this way frequently showed themselves incapable of any design or construction work. The best hope for improvement in professional education lay in assuring university training to those fitted for it. Engineers recognised, too, that the community would be better served if more were made of the workman's brains and less of his muscle. The rough-and-ready estimating now in vogue should give place to scientific calculation.

Section I (*Sanitary Science and Hygiene*).—Taking as the subject of his presidential address "Accuracy in Medicine," Dr. J. H. L. Cumpston stated that two things were urgently necessary: (1) the education of the public to a proper conception of the need for accurate methods in medical diagnosis and treatment, and (2) the provision, within

practicable access of all medical practitioners, of the equipment necessary for the employment of these methods. Some form of common service must be provided so that each practitioner could have access either to the necessary instruments or apparatus or to some specialist who had the necessary knowledge and equipment. In the metropolitan areas such service was already largely provided by hospitals, specialists, and laboratories, but the provincial and country towns were at a disadvantage. The prevention of disease should be the first aim of medical science. The technical apparatus required for the application of many of the laws of public health was not unduly extensive, and could be made to serve large populations. There were enough trained medical men to make a commencement, and laboratories to serve all public health purposes should be forthwith established at all the principal country centres.

Section J (*Mental Science and Education*).—"The Need for the Scientific Study of Education" was the subject of Prof. A. Mackie's presidential address. He urged the need for a survey of the mental character of the school population for the effective practice of teaching and organisation, pointing out that the tests of general and scholastic intelligence devised by standard authorities must be re-standardised before they can be usefully employed for Australian children. The question of school examinations also stood in need of scientific investigation. The study of the errors made by pupils in the various branches of school-work might be expected to throw much light on the curative and preventive measures that should be adopted.

Section K (*Agriculture*).—That education should be general rather than special up to the age of fifteen was the plea of Prof. A. J. Perkins in his presidential address entitled "Agricultural Education." The bulk of those following agricultural pursuits were, in the main, home-trained, and the need for any other form of training was to some extent forced into the background. The State would do well to maintain agricultural colleges as half-way houses between the town and the country. Practical training in farming was of importance in conjunction with theoretical instruction, and the establishment of university training and chairs of agriculture must be backed up by the selection of adequate scientific staffs. Every effort should be made to overcome the effects of isolation of those engaged in agricultural pursuits. An extension of the agricultural bureau system of South Australia was advocated, under which agriculturists were grouped into local branches, where local interests were discussed and arrangements made for visits of experts and experimental work.

Section L (*Veterinary Science*).—The president, Prof. H. A. Woodruff, delivered an address on "The Development of the Present Conception of Immunity."

At a joint discussion (Sections A and B) on "The Applications of Physical and Chemical Science in the Great War" Mr. A. E. Leighton (Director of the Commonwealth Arsenal) gave a brief sketch of two war activities on the part of applied chemistry and the particular significance they held for Australia. These were the important factors of cordite and high explosive. It must be remembered, said Mr. Leighton, that Australia was not in a fortunate position as a manufacturing country, and her provision against attack must take the form of finished munitions. Until the industries of Australia were in a position to maintain a flow of munitions commensurate with requirements, they must adhere to the policy of importing and holding stocks. Australia had illimitable quantities of iron-ore, but what the munition-worker wanted was steel rolled to a certain shape. He wanted caustic soda and chlorine. The tariff and recent legislation had given promises that the Ministry intended to encourage supply. But to become a manufacturing community was a slow and costly process. Protection should be scientific in the sense that in protecting the industry the people should also be protected from rule-of-thumb methods. The number of chemists and engineers should be increased, for without them the illimitable resources of the country could not be treated.

Dr. A. C. D. Rivett particularly directed attention to the lesson already learned by Germany and England, that the possession of flourishing chemical industries was not merely a means to material prosperity in times of peace, but also absolutely essential as an instrument of warfare. Men in Australia had to realise that to build up the chemical manufactures of Japan or America, or any other country, and to neglect their own, was precisely the same as building up other armies and navies while forming none of their own. Dr. Rivett urged the adoption of the following motion:—"That these sections of the Australasian Association for the Advancement of Science, recognising the vast importance of chemical science in modern warfare, recommend that the general council urge upon the Federal Ministry the necessity for fostering chemical industries in Australia under such conditions as will ensure the maximum readiness for the production of munitions of war in case of need." The motion was seconded by Prof. Orme Masson, and agreed to unanimously.

Prof. T. H. Laby read a paper on "The Organisation of Science in Australia." Prof. Laby pointed out that, although during the war period science had been applied most successfully to assist in the exploitation of Nature's resources for our material benefit, a greater achievement would be to instil into the national mind the high ideals which have actuated so many men of science. This would be assisted by a re-organisation of science such as had been undertaken by Great Britain, the United States, and Japan. The lack of any single Australian scientific society was also commented on, the political control exercised over the Commonwealth Institute of Science and Industry was criticised, and the position of the mathematical and physical sciences in Australia was indicated as illustrative of the need for organisation. In conclusion, the author urged the formation of an Australian scientific society representative of all research workers in science in Australia, which would be able to act in an advisory capacity to the Commonwealth Government upon scientific matters. This plea has now been answered to a large extent by the formation of the National Research Council referred to last week.

Numerous papers were read to the various sections and a number of joint discussions on problems common to more than one section were held. Especially is the association to be congratulated on the formation of a National Research Council, which should prove a real asset for the advancement of science in Australia.

University and Educational Intelligence.

BRISTOL.—Sir Isambard Owen, vice-chancellor of the University, is to retire at the end of the present session, having reached the age limit of seventy years prescribed by the rules of the Treasury with regard to superannuation.

LONDON.—Dr. R. R. Gates has been appointed to the University chair of botany tenable at King's Col-

lege in succession to Prof. W. B. Bottomley. He was appointed University reader in botany at that college in 1919, and has since that date been in charge of the department in the absence of Prof. Bottomley.

Mr. D. M. S. Watson has been appointed as from August 1 next to the Jodrell chair of zoology and comparative anatomy at University College in succession to Dr. J. P. Hill, now professor of embryology. Since 1912 Mr. Watson has been lecturer in vertebrate palæontology at that college. He has also lectured in the Universities of Munich, Cape Town, Sydney, California, Michigan, and Chicago.

Mr. H. G. Jackson has been appointed as from August 1 next to the University readership in zoology tenable at Birkbeck College. In 1912 Mr. Jackson was appointed research assistant to Prof. Herdman at the University of Liverpool, and since 1913 has been lecturer in zoology at the University of Birmingham.

Dr. William Wilson has been appointed as from September 1 next to the University chair of physics tenable at Bedford College. Since 1919 Dr. Wilson has been senior lecturer in physics at King's College, and in 1920 he received the title of reader in physics.

The following doctorates have been conferred:—*D.Sc. in Botany:* Mr. F. G. Gregory, an internal student of the Imperial College—Royal College of Science, for a thesis entitled "The Increase in Area of Leaves and Leaf-surface of *Cucumis sativus*." *D.Sc. in Chemistry:* Mr. H. Yaroslav, an internal student of University College, for a thesis entitled "The Electro-affinity of Aluminium." *D.Sc. in Zoology:* Mr. L. T. Hogben, an external student, for a thesis entitled "Studies on Synapsis." *D.Sc.* (*Engineering*)*:* Mr. F. E. Rowett, an external student, for a thesis entitled "The Resistance to the Flow of Oils through Rubber and Steel Pipes," and other papers.

Mr. L. H. Dudley Buxton has been elected to an Albert Kahn travelling fellowship for the year 1921–22. These fellowships, which are now of the value of 1000*l.* each, were founded in 1910 by Mr. Albert Kahn, of Paris, to enable the fellows to travel for at least one year in foreign countries, so that by the study and comparison of national manners and customs, and of political, social, religious, and economic institutions, they may become better qualified to instruct and educate their fellow-countrymen.

DR. A. G. GIBSON, lecturer in morbid anatomy in the University of Oxford, is to deliver the Schorstein memorial lecture at 4 o'clock on Friday, June 3, at the London Hospital Medical College. The subject will be "Chronic Inflammatory Diseases of the Spleen."

THE summer meeting of the Association of Science Teachers will be held at Cambridge on Saturday, July 9. There will be a short business meeting in the morning at Girton College (by kind permission of the Mistress of Girton), where members will have lunch. In the afternoon Dr. F. W. Aston will give a lecture on "Atoms and Isotopes."

Two research scholarships of the annual value respectively of 100*l.* and 75*l.* are being offered by the Huddersfield Technical College, the object being the encouragement of research upon problems connected with the coal-tar industry in Great Britain. Further information can be obtained from Dr. H. H. Hodgson, Colour Chemistry Department, Technical College, Huddersfield.

Two lectures entitled "The History of Map-making" and "Maps of the Principal Voyages of the Sixteenth Century" are being delivered at 7 p.m. on Mondays at Birkbeck College (University of London), the first on Monday last and the second on June 6, by Mr. W. H. Barker. In connection with these lectures there is being held an exhibition of maps, charts, and globes illustrating the history of map-making and geographical discovery. Admission to the lectures is free without ticket.

RESEARCH scholarships in agricultural and veterinary science (not more than five in number), each of the annual value of 200*l.* and tenable for two years, are being offered by the Ministry of Agriculture and Fisheries. The agricultural scholarships are open to graduates with honours in science of a British university. The veterinary scholarships are open to students who have secured the diploma of the Royal College of Veterinary Surgeons. Nominations on the prescribed form must reach the Secretary, Ministry of Agriculture and Fisheries, 4 Whitehall Place, S.W.1, by, at latest, July 15 next.

THE University of the West at Bristol, of which Lord Haldane is the Chancellor, has issued a striking illustrated appeal for the sum of 1,000,000*l.* for endowments and maintenance. The appeal takes the form of a series of thirty delightfully executed and printed folio drawings, not only of existing buildings connected with the University in Bristol and in its neighbourhood, but also of buildings in the course of erection on an admirable and unencumbered site of 13½ acres near the centre of the city, which are due to the munificence of the late Mr. H. O. Wills and his sons, Messrs. G. A. and H. H. Wills. The appeal is accompanied by a sheet of three remarkable cartoons by Mr. Louis Raemaekers illustrating the need for the more complete education of the youth of the nation, both men and women, who did it such splendid service in the eventful years 1914–18. Under the cartoons are respectively the remarkable, but true, words: "Genius is not drawn from any exclusive class or caste, but from the cradles of the nation; no longer can we afford to waste the development of ability if we are to maintain leadership." "It is the universities which train; it is in them that the fullness of knowledge dwells." "They look forward to an era of research, experiment, discovery, invention, and intellectual progress that shall surpass even the record of the century that is past." Not only are efficient buildings and equipment essential, but even more so are opportunities of free development unhampered by bureaucratic regulations, and of adequate maintenance for teachers and their satisfactory superannuation, whilst the provision of numerous maintenance scholarships is a necessity if the able children of the working community are to enjoy the advantage of a university education. No difficulty should be found in raising the funds necessary to ensure adequate support for the universities now so urgently appealing for funds in various parts of the country if only the wealthy members of society and the various local authorities within their respective areas would realise their responsibilities. There has arisen a great demand of late throughout England for the more complete provision of continued and higher education, and if this demand is to be met it is essential that the universities from which the chief inspiration should be derived shall be maintained in the fullest efficiency of means and methods.

Calendar of Scientific Pioneers.

June 2, 1886. James Apjohn died.—A lecturer and professor of chemistry at Dublin for more than fifty years and a vice-president of the Royal Irish Academy, Apjohn wrote on chemistry, mineralogy, and meteorology, and his name is connected with a formula for ascertaining the dew-point.

June 2, 1901. John Viriamu Jones died.—After a distinguished career at Oxford, Jones in 1881, at the age of twenty-five, became principal of Firth College, Sheffield, and two years later was made the first Principal of University College, South Wales. His principal scientific work referred to accurate determinations of electrical and physical standards.

June 2, 1903. Andrew Ainslie Common died.—An engineer by profession, Common devoted himself to the construction of large reflecting telescopes with silver-on-glass mirrors. Harvard and Lick Observatories possess instruments from his Ealing workshops. He received the gold medal of the Royal Astronomical Society for his photographs of the great nebula in Orion, and in 1895–96 was president of the society.

June 3, 1657. William Harvey died.—Born at Folkestone on April 1, 1578, Harvey was educated at Canterbury, Cambridge, and Padua, and, after graduating in medicine, settled in London. Appointed physician to St. Bartholomew's Hospital in 1609, six years later he became Lumleian lecturer at the College of Physicians, where he first publicly taught the doctrine of the circulation of the blood. His celebrated treatise, "Exercitatio Anatomica de Motu Cordis et Sanguinis," was published at Frankfort in 1628. He was physician to James I. and Charles I. His tomb is at Hempstead, near Saffron Walden.

June 3, 1822. René Just Haüy died.—After many early privations, Haüy became a teacher in the College of Navarre in Paris. An accident to a crystal of calcareous spar led him to the discovery of the law of crystallisation. His first memoir on the structure of crystals appeared in 1784. He afterwards held important official positions, among which was the chair of mineralogy at the Jardin des Plantes.

June 5, 1716. Roger Cotes died.—In 1706, at the age of twenty-four, Cotes became the first Plumian professor of astronomy and natural philosophy at Cambridge. He assisted Newton in the revision of the "Principia," with Whiston gave one of the earliest courses of experimental philosophy, and in Trinity College erected an observatory. A man of exceptional genius, Newton, referring to his work on optics, remarked: "If Mr. Cotes had lived we should have known something."

June 7, 1826. Joseph von Fraunhofer died.—A glass-cutter's apprentice, Fraunhofer in 1804 became associated with Reichenbach, the instrument-maker. A skilful maker of telescopes, he invented the stage micrometer, the diffraction grating, and a form of heliometer. He discovered the dark lines in the spectrum previously seen by Wollaston, and laid the foundations of solar and stellar chemistry.

June 8, 1695. Christiaan Huygens van Zuylichem died.—The greatest of Dutch physicists, Huygens is a connecting link between Galileo and Newton. Born at The Hague in 1629, he spent many years of his life in Paris. He improved the telescope, discovered the first of Saturn's satellites, explained the nature of Saturn's ring, adapted the pendulum to clocks, and advocated the undulatory theory of light. His principal works were his "Traité de la lumière" and his "Horologium Oscillatorum." He is buried in St. Peter's, Leyden.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, May 26.—Prof. C. S. Sherrington, president, in the chair.—Sir Alfred **Ewing**: The atomic process in ferro-magnetic induction. The author's modification of Weber's theory of magnetisation is reconsidered in the light of (1) modern views regarding the structure of the atom and (2) the X-ray analysis of crystal structure. The rotatable Weber magnet seems to be an attribute of the atom, probably an electron system within it. Metallic iron is now known to be an aggregate of crystals, in each of which the space-lattice is the centred cube, with its atoms most closely grouped along the trigonal axes. It is along these axes that the Weber elements will point. Consequently an iron crystal is not magnetically isotropic. The small quasi-elastic or reversible part preceding the much larger changes which involve hysteresis corresponds to a reversible deflection of the Weber magnets through a small angle, generally of an order of 1°. The theory of the equilibrium of a row of magnets is considered. Experiments in which rows of Robison magnets with ball ends have their equilibrium upset by an extraneous field confirm the theory. The field which would break up rows of magnets set in the space-lattice close enough together to bring the reversible deflection within the above limit is calculated; it is larger than the field that suffices to produce strong magnetisation in iron, suggesting that the ordinary laws of force between magnetic elements cease to apply at interatomic distances.—C. D. **Ellis**: The magnetic spectrum of the β-rays excited by the γ-rays. The magnetic spectra of the β-rays ejected from various elements by the γ-rays of radium B have been examined by the focussing method. The positions of three strong lines occurring in the magnetic spectrum of radium B depend on the metal target used. Assuming that each of these three lines is due to a definite γ-radiation, it is shown that the energy of the β-rays forming a line is equal to an energy characteristic of the γ-radiation *minus* the work necessary to remove an electron from the K ring of the atom. By application of the quantum theory the frequency of the γ-rays can be determined from these characteristic energies. The natural β-ray spectrum of radium B can be explained in this way, the stronger lines resulting from the conversion of the γ-rays in the K ring, and the weaker lines from a similar conversion of the same γ-rays in the L ring.—S. **Datta**: The spectra of the alkaline earth fluorides and their relation to each other. A survey of the spectra of these compounds has been made and several new bands observed. These helped in the identification of homologous series of bands in the different spectra, and have suggested an empirical relation amongst them, based on the constants of the series equations and the molecular weight or the molecular number of the respective compounds. Starting with the series equation of the band-heads, an explanation has been given of the appearance of a "tail" in some of the bands. It has been shown that the frequency of the "tail" is a maximum or a minimum, and that the difference in wave-numbers of the heads and tails of the similar series is constant for the same compound, but varies from one another in a definite way.—Dr. W. L. **Balls**: A simple apparatus for approximate harmonic analysis and for periodicity measurements. The error involved in the use of this apparatus need not exceed 3 per cent. Its outstanding advantage is the speed with which determinations may be made. Thus in determinations of periodicity some fifty trial periods can be examined in less time than is required for the

computation of a single trial period under the periodogram arithmetical method.—Dr. G. R. **Goldsbrough**: The influence of satellites upon the form of Saturn's ring. The ring is supposed to be made up of small particles arranged in concentric circles and rotating about the primary. The satellite is assumed to follow an unperturbed circular orbit, and the influence of the rings upon one another is assumed negligible. To a close degree of numerical approximation the satellite Mimas is responsible for the position and width of Cassini's Division and for the clean-cut termination of the whole ring. Satellite Rhea accounts for the clean-cut commencement of the inner ring (or ring B), while a probable explanation is offered of the existence of the crêpe ring. If m be the mass of any particle, and M the mass of Saturn, and n the number of particles in any single ring, it is shown that

$$0<m/M<1\cdot8/n^3.$$

The maximum mass of a particle is thus just below the limit given by Maxwell.—Dr. H. **Jeffreys**: Certain geological effects of the cooling of the earth. Mechanical consequences of the cooling of the earth from its formation to its present state are considered. The former fluidity of the earth is assumed and the information provided by radio-activity is utilised. The thermal contraction available for mountain-building is of the same order as that required to account for existing mountains. The Pacific type of mountain range can be explained as due to greater cooling and consequent greater strength of the rocks below the ocean. Isostatic compensation of surface inequalities is due to variation in the thickness of the light rocks constituting the crust, combined with plastic flow below. The fact that oceans have extensive regions of less depth in the middle is explained and theories of the formation of continents and geosynclines are suggested.—T. **Kikuchi**: The moving striations in a neon tube.

Geological Society, May 4.—Mr. R. D. Oldham, president, in the chair.—H. Hamshaw **Thomas**: An Ottokaria-like plant from South Africa. The discovery in the Vereeniging Sandstones of the Transvaal of a fossil plant which bears considerable resemblance to the genus Ottokaria is recorded. The specimen agrees with known examples in size, and in having an almost circular head seated upon a stalk; an additional feature is a thin flattened structure projecting beyond the head, provisionally called the "wing." Ottokaria was probably a reproductive structure, and its association with Glossopteris suggests a possible connection with this plant. The name of *Ottokaria Lesliei* is assigned to the specimen.—Dr. A. B. **Walkom**: On Nummulospermum, gen. nov., the probable megasporangium of Glossopteris. Seeds associated with some fronds of Glossopteris from Queensland are described under the name *Nummulospermum bowenense*. The vascular system is also partly described. The seeds have not been found in actual connection with Glossopteris fronds. Remarks are added on the scale-leaves of Glossopteris, and on the affinities of Glossopteris, which is classed with the Cycadofilicales. The anatomical features of the seeds suggest relationship with the Trigonocarpales.—Agnes **McDonald** and Dr. A. E. **Trueman**: The evolution of certain Liassic gastropods, with special reference to their use in stratigraphy. The gastropods dealt with are turriculate forms, formerly called Cerithium, now referred to the family Procerithidæ, Cossmann, and Chemnitzia, now referred to the family Loxonematidæ, Koken. Suggestions for the classification of these gastropods, based on ontogenetic and other evidence, are made. The position and characters of the ornamentation have proved of value in classification, when taken in conjunction with the other characters of the shell. In numerous series acceleration or retardation of development is indicated, and examples of homœomorphy of several types have been noted. The Procerithidæ of the Lower Lias are chiefly species of Procerithium, in which the flattish whorls have reticulate ornament based on three spirals. This series probably gave rise to many recent Cerithidæ which have more than four spirals. Other genera of Procerithidæ are recognised. The pupoid forms which have been grouped in the genus Exelissa are regarded as catagenetic descendants of diverse species of Procerithium. The Loxonematidæ of the British Lias are of two types, one with axial ornament (Zygopleura), the other with axials and feeble spirals (Katosira). Each of these genera shows during the Lias an increase in the number and curve of the axials. In development axials always appear before spirals among the Loxonematidæ, while spirals are developed first among the Procerithidæ.

Physical Society, May 13.—Sir William Bragg, president, in the chair.—L. **Hartshorn** and E. S. **Keeping**: Notes on vacuum tubes used as detectors of electrical oscillations. The paper describes the development of a robust form of vacuum tube which was used as a detector of electrical oscillations in the "wireless" circuits carried by aeroplanes. Platinum electrodes are avoided, being replaced by strips of tinfoil, to which contact may be made by the spring clips holding the tube in position. It was found that when a discharge is passed through such a tube the walls are affected in such a way that thenceforth it is much easier to get a discharge to pass. The change produced by the first discharge is annulled by heating the tube above 210° C. Further, if the walls are coated on the inside with a metallic film, this first discharge is unnecessary, and the tube is unaffected by heating, but when the walls are coated with an insulator it is, if anything, more difficult to pass a discharge. A silica tube behaves like one coated with metal. It seems possible that the change in the tube may be due to the formation of a layer of gas molecules on the walls by the first discharge. The explanation of the behaviour of the silica tube is a difficulty.—B. W. **Clack**: The coefficient of diffusion of certain saturated solutions. This paper gives an account of experiments on the diffusivity of saturated solutions of KCl, NaCl, and KNO_3 at constant temperatures near 18° C., when the steady state of diffusion has been attained, employing a method similar to that previously used by the author (Proc. Phys. Soc., vol. xxi., p. 863, 1908; vol. xxiv., p. 40, 1911; vol. xxvii., p. 56, 1914; vol. xxix., p. 49, 1916). The solution under investigation is maintained at complete saturation by the presence of salt crystals in the diffusion vessel; the theory takes into account the change in volume of this salt as it dissolves, and an expression is obtained for the coefficient of diffusion at complete saturation, which depends on the rate of change in weight of the diffusion vessel with time. The experimental results are found to agree very closely with the values obtained by extrapolation from the results previously found for less concentrated solutions. By the present paper the author has thus extended the range of concentration over which he has studied diffusion from very dilute solutions right up to complete saturation.—Dr. G. D. **West**: Experiments on thermal transpiration currents. Theoretical considerations are first introduced to show that if a radial temperature gradient be maintained over a disc so that the centre is the hottest part, thermal transpiration currents sweep radially inwards over the surface of the disc, and discharge themselves more or less radially outwards in the upper regions. To detect

these currents a narrow strip of foil is used which is placed perpendicular to the disc and to one side of the hot region. When at a considerable perpendicular distance from the disc, and when the gas pressure is sufficiently low to eliminate convection currents, the deflections of the strip of foil are always away from the hot region. When, however, the strip is placed very close to the disc its deflections over a certain range of gas pressure are towards the hot region. These facts are explained by the tendency of the thermal transpiration currents to drag the strip with them. The paper emphasises one of the essential differences between thermal transpiration currents and convection currents, namely, that while the latter clearly depend on gravitation, the former do not.

CAMBRIDGE.

Philosophical Society, May 2.—Prof. A. C. Seward, president, in the chair.—E. K. **Rideal**: Active molecules in physical and chemical reactions. The chemical nature of evaporation is established by the calculation of heats of reaction from spectral data with the aid of the quantum theory. Evaporation is regarded as a monomolecular chemical change; equating the rate of evaporation to the rate of condensation when equilibrium is attained, the unknown integration constants of the Clapeyron-Clausius equation, and thus the chemical constants of Nernst, have been determined. The values obtained agree closely with those experimentally derived. The energy of activation is probably an average value representing the mean energy of activation of a gram-molecule of reactant, and a formula from which it can be calculated is given. The hypothesis receives support from the fact that at the critical temperature the radiation intensity is at a maximum for light of the particular frequency with which the active molecules are in equilibrium. Wien's law $\lambda_m T = \text{constant} = 0{\cdot}28986$ is shown to be a simple variant of Trouton's rule $L = KT_c$. The value of K as calculated from the purely radiation-derived data of Wien is found to be 9·866. The latent heats of evaporation calculated from Wien's law are found for non-associating liquids to agree very closely with those derived from vapour-pressure data. The equilibrium of the active molecules with the radiation may be ascribed to resonance.—Dr. **Hartridge**: (1) An experiment which favours the resonance theory of hearing. When the phase of a musical note is suddenly altered by π the note fades momentarily to silence, and returns a moment later to its former intensity. (2) A criticism of Wrightson's theory of hearing. A mathematical analysis is advanced to demonstrate the existence of the coincidences required by the theory between the lengths of the periodically repeated time-intervals in the separate tones and those present when all the tones are sounding together. They are found to be imaginary. (3) A method of projecting interference bands. If a celluloid replica diffraction grating be mounted in optical contact with a polished metal surface, and a beam of approximately monochromatic light be projected into it, the spectra produced are crossed by interference bands. (4) A method of projecting absorption spectra. If a celluloid replica diffraction grating be mounted on the hypotenuse of a right-angled glass prism, with the rulings parallel to the apex, and a beam of approximately parallel light be caused to enter along the normal to the base, a spectrum of wide dispersion and great intensity is produced. (5) The shift of absorption bands with change of temperature. The absorption bands of blood pigment in the visual region of the spectrum have been observed at the temperature of evaporation of liquid air and liquid nitrous oxide by drying films of a solution of the pigment in gelatine on glass slabs and then immersing them in the cold liquids. It is found that such films retain their transparency. The reversion spectroscope shows that both α- and β-bands are sharper at low temperatures, and that they are displaced towards the violet end of the spectrum approximately 41 Å. The change in wave-length cannot be due to change in refractive index of the solvent, because dissolving blood pigment in glycerine instead of in water leaves the band unchanged.—Dr. H. S. **Carslaw**: The cooling of a solid sphere with a concentric core of a different material. The method used is to study the contour integrals over a certain standard path. Estimates of the age of the earth founded upon the present surface temperature gradient are discussed.—C. R. G. **Cosens**: An alignment chart for thermodynamical problems.—Dr. T. J. I'A. **Bromwich**: Symbolical methods in the theory of conduction of heat.—C. V. **Hanumanta Rao**: A property of focal conics and of bicircular quartics.

DUBLIN.

Royal Dublin Society, April 26.—Dr. F. E. Hackett in the chair.—J. **Davidson**: Biological studies of *Aphis rumicis*.—H. G. **Becker**: A new principle in blow-pipe construction. The essential features of a quick-change blow-pipe to operate with air at constant pressure, such as is supplied by a blower driven by power, are discussed and the necessity for air-jets of different bore for the different flames is emphasised. The tubular shape common to all hitherto existing blow-pipes is shown to be unnecessarily cumbersome, and is therefore abandoned. A form of blow-pipe giving a great range of flames (including a flat blow-pipe flame), each provided with an air-jet of suitable size and allowing of instantaneous change from one to the other, was described, and an actual blow-pipe constructed on this principle was shown in operation.

PARIS.

Academy of Sciences, May 9.—M. Georges Lemoine in the chair.—F. **Widal**, P. **Abrami**, and J. **Hutinel**: Comparative researches on the working of the liver following surgical anæsthesia produced by chloroform, ether, nitrous oxide, or novocaine. It has been shown in previous communications that slight functional alterations in the liver can be detected by simple leucocyte counts, after absorption of a glass of milk. The method has been applied to the study of the functional derangements of the liver produced by anæsthetics. Chloroform, ether, and nitrous oxide produced derangements of function, chloroform acting most powerfully. Injections of novocaine were without effect on the liver.—M. Georges Urbain was elected a member of the section of chemistry in succession to the late M. Emile Bourquelot.—F. **Vaney**: The polynomials of Laguerre.—A. **Angelesco**: A representation of polynomials by integrals.—R. **Birkeland**: The convergence of the developments which express the roots of the general algebraic equation by a sum of hypergeometric functions of several variables.—B. **Gambier**: Real non-unicursal algebraic curves with constant torsion.—M. **Idrac**: Experimental studies on hovering flight. In an earlier note the opinion was expressed that wherever birds are hovering in stationary flight they are always in a zone where the wind has a vertical ascending component. Results confirming this view are now given, and records of the variations in temperature and pressure of the air taken on apparatus carried by captive balloons are reproduced.—J. **Vallot**: Study of the diffuse radiation of the sky compared with the direct solar radiation. The total diffuse radiation is considerable, and may amount to one-third of the solar radiation.—A. **Leduc**: A new equation of state for gases based on a know-

ledge of the internal pressures.—H. **Abraham** and R. **Planiol**: The use of the Baudot telegraph in wireless telegraphy. The Baudot quadruple instrument used in the ordinary way records 7200 words per hour. A description of the adaptation of this to wireless transmission is given. The first experiments were made across Paris; later the apparatus was successfully used between Paris and Nogent-le-Rotrou.—M. St. **Procopiu**: Electrical double refraction of mixed liquids and crystalline structure.—A. E. **Lindh**: The absorption spectra of chlorine for the X-rays. All chlorides in which the chlorine is monovalent have similar X-ray spectra, but there is a displacement of the limits of absorption in $KClO_3$ and $KClO_4$, compounds in which the valencies are 5 and 7.—D. **Coster**: The principle of combination and the law of Stokes in the X-ray series. —MM. M. **Menard** and **Pestel**: Concerning the danger of radiological installations. The authors conclude that, provided the usual precautions required for the safety of the operator are taken, there is no real danger to third parties in neighbouring rooms.—A. **Tian**: A theory of the slow hydrolysis of salts.—MM. P. **Jolibois** and **Bouvier**: The reversibility of the reaction $CaCO_3 = CO_2 + CaO$. The self-recording apparatus described in an earlier paper has been applied to the study of the dissociation of calcium carbonate. The heating and cooling curves are not the same, and hence the reaction is not strictly reversible.—G. **Dupont**: Contribution to the study of the acid constituents of the exudation of the maritime pine. The composition of pimaric acid. Pimaric acid purified by Vesterberg's method is a mixture of 37 per cent. of dextropimaric acid and 63 per cent. of the lævo-acid.—L. **Longchambon**: The measurement of the rotatory power in biaxial crystals.—L. **Cayeux**: The petrographic *rôle* of fossil Alcyonaria deduced from the analysis of the Jurassic iron minerals of France.—L. **Joleaud**: A deep boring which demonstrates the existence of transported strata in northern Tunis. A trial boring for oil made at Aïn-Rhelal started in the Middle Miocene, then passed through the Trias (630 metres), and finally met with strata undoubtedly belonging to the Upper Cretaceous.—F. **Ehrmann**: The Trias of the Kabylie des Babors (Algeria).—J. **Beauverie**: The resistance of mitochondria and plasts, and relations with attacks by parasites.—G. **Mangenot**: The structure of the antherozoids of the Fucaceæ.—R. **Lance**: The use of coloured screens for fighting against cryptogamic diseases of plants. The plants are sprayed with solutions containing blue, green, and violet dye. The fluid dries and leaves the parts of the plant covered with a colour screen allowing blue, violet, and ultra-violet light to pass. No results of the treatment are given.—R. **Lance**: An anticryptogamic product. A proposal to use salts of zinc for spraying plants.—M. **Mirande**: Seeds giving hydrogen sulphide by fermentation belonging to the family of the Papilionaceæ. Many leguminous seeds, including beans, peas, and lentils, when moistened with water undergo a spontaneous fermentation, one of the products of which (sulphuretted hydrogen) is poisonous.—C. **Champy**: The experimental change of sex in *Triton alpestris*. A male, subjected to starvation, had its testicle replaced by a fatty band containing neither spermatocytes nor spermatozoids. Two animals after winter starvation were intensively fed. The external colouring changed from male to female in character. One of these was killed, and showed the adipose band; the second, killed two months later, showed a genital gland (section shown in diagram) corresponding to the ovary of a young female.—L. **Roule** and F. **Angel**: Fishes of the family of the Diretmideæ and their place in classification.—A. **Gruvel**: The geographical distribution of some Madagascan lobsters and their commercial exploitation.—J. **Dragoiu** and F. **Vlès**: The cytological consequences of the osmotic arrest of cell division. The increase of the external osmotic pressure first retards, then stops, the division of the cytoplasm. With additional increase of osmotic pressure the internal evolution of the cell is progressively changed in a regular manner. The whole process simulates a kind of regression of nuclear evolution.—M. **Doyon**: The use of chloroform for the preparation of nucleo-proteids and nucleic acids active *in vitro* on the blood. The complexity of the action of the nucleic acids *in vitro*.—M. **Bordier**: The usefulness of diathermal d'Arsonvalisation in atonic wounds.

Diary of Societies.

THURSDAY, JUNE 2.

INDUSTRIAL WELFARE SOCIETY (at 51 Palace Street, S.W.1), at 10.30.—Dr. R. M. Wilson: Medical Service in Industry.—Prof. E. L. Collis, Dr. T. M. Legge, and Dr. H. Ross: Discussion on Health Problems in Industry.

ROYAL SOCIETY OF MEDICINE (Laryngology Section) (Summer Meeting), 2.30 to 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir Alexander C. Mackenzie: Beethoven.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital), at 4.30.—Prof. G. Dreyer: A New Departure in the Serum Diagnosis of Syphilis.

ROYAL SOCIETY, at 4.30.—Dr. T. M. Lowry and Dr. C. P. Austin: Optical Rotatory Dispersion (The Bakerian Lecture).

LINNEAN SOCIETY, at 5.—Prof. Garstang and Others: Discussion on Biogenetic Law (Recapitulation).

CHILD-STUDY SOCIETY (at Royal Sanitary Institute), at 6.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—H. M. Fletcher: Building a House.

CHEMICAL SOCIETY, at 8.—H. King: Derivatives of Sulphur in Commercial Salvarsan. Part I.—S. Glasstone: Physical Chemistry of the Oxides of Lead. Part I. The Solubility of Lead Monoxide.—M. O. Forster and W. B. Saville: Studies in the Camphane Series. Part XXXIX. p-Aminophenylaminocamphor (Camphoryl-p-phenylenediamine).—K. Stratton and J. R. Partington: Latent Heats of Fusion. Part I. Benzophenone, Phenol, and Sulphur.—G. T. Morgan and H. D. K. Drew: Researches on Residual Affinity and Co-ordination. Part V. Gallium Acetylacetone and its Analogues.—J. C. Thomlinson: Analysis of Cresol Disinfectants.—G. T. Morgan and D. Webster: Diazo-derivatives of 4-aminophenyl-4′-methylbenz-2′:7′-thiazole (Dehydrothio-p-toluidine).—A. K. Macbeth and D. D. Pratt: The Labile Nature of the Halogen Atoms in Substituted Nitromethanes.—K. G. Naik: The Formation and Properties of Dithioketones ($R_2C:S:S$) and Dithioethers ($R_2S:S$). Part II.—K. G. Naik: The Formation and Properties of Dithioketones ($R_2C:S:S$) and Dithioethers ($R_2S:S$). Part III. Interaction of Sulphur Monochloride with Organic Compounds containing the grouping

$$—CO—CH_2—CO—CH_2—CO—.$$

K. G. Naik: The Formation and Properties of Dithioketones ($R_2C:S:S$) and Dithioethers ($R_2S:S$). Part IV. Interaction of Sulphur Monochloride with Organic Compounds containing —CO—CH_2—CO— grouping, forming the Part of a Closed Ring.—K. G. Naik: The Formation and Properties of Dithioketones ($R_2C:S:S$) and Dithioethers ($R_2S:S$). Part V. Nitration of Dithioketones and Dithioethers.—K. G. Naik: Interaction of Sulphur Monochloride with Organic Acid Amides.—S. J. Lewis and F. M. Wood: A New Adjustable Thermostat for all Temperatures between 0° and 100°.—H. Burton and J. Kenner: The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part III. The Partial Reduction of the Dinitrotoluenes by Stannous Chloride and Hydrochloric Acid.—J. Kenner and E. Witham: The Influence of Nitro-groups on the Reactivity of Substituents in the Benzene Nucleus. Part IV. The Condensation of Ethyl 3- and 5-nitro-o-Chlorobenzoates with Hydrazines.

SOCIOLOGICAL SOCIETY (at 65 Belgrave Road), at 8.15.—Prof. Abercrombie: The Municipal Survey of Sheffield.

FRIDAY, JUNE 3.

ROYAL SOCIETY OF MEDICINE (Laryngology Section) (Summer Meeting), 10 to 1.

ASSOCIATION OF ECONOMIC BIOLOGISTS (in Botanical Lecture Theatre, Imperial College of Science), at 2.30.—F. L. Engledow: Methods of Increasing Yield in Crop Plants.—C. B. Saunders: Some Problems of Seed Testing.—W. Brown: The Physiology of Infection.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at 11 Chandos Street, W.1) (Adjourned Meeting), at 5.—Lt.-Col. H. Kirkpatrick: Some Points on Trachoma.—C. França: An Early Portuguese Contribution to Tropical Medicine.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—M. Adams: Eyes in Portraiture.

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. L. Huxley: Chronicles of the *Cornhill*.

SATURDAY, JUNE 4.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Dr. R. S. Rait: Scotland and France.

MONDAY, JUNE 6.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Rev. Prebendary H. E. Fox: The Roman Wall in North Britain.

INSTITUTE OF ACTUARIES (Annual General Meeting), at 5.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—Dr. L. Levy: Industrial Respirators.—Prof. K. G. Naik: The Gold and Silver Thread Industry in India.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—E. Teichman: Journeys in Kam.

TUESDAY, JUNE 7.

ROYAL HORTICULTURAL SOCIETY, at 3.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Sir James Frazer: London Life: Time of Addison.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND (at Maudsley Hospital, Denmark Hill), at 4.30.—Sir Frederick Mott: Second Maudsley Lecture.

ZOOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. F. M. Chapman: The Distribution of Bird-life in the Urubamba Valley of Peru.—S. Maulik: New Indian Drilid Beetles.—Prof. J. P. Hill: Exhibition of Some Marsupial Embryos, especially the Koala and the Wombat.—R. I. Pocock: The External Characters of the Koala (Phascolarctos) and Some Related Marsupials.—Dr. C. F. Sonntag: The Comparative Anatomy of the Koala (*Phascolarctos cinereus*) and the Vulpine Phalanger (*Trichosurus vulpecula*).

WEDNESDAY, JUNE 8.

BRITISH SCIENCE GUILD (Annual Meeting) (at Goldsmiths' Hall, Foster Lane), at 3.—Lord Montagu of Beaulieu: The Work of the Guild.—The Dean of St. Paul's: The Road to Ruin and the Way Out.—Sir Richard A. S. Redmayne: The Importance of Research in Promoting the Development of the Mineral Industries.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—Dr. W. Fraser Hume: The Relations of the Northern Red Sea and its Associated Gulf Areas to the "Rift" Theory.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section) (at Savoy Place), at 6.—Prof. J. S. Townsend: Electric Oscillations along Straight Wires and Solenoids.

THURSDAY, JUNE 9.

INSTITUTION OF MINING ENGINEERS (at Geological Society), at 11.—Third Report of the Committee on "The Control of Atmospheric Conditions in Hot and Deep Mines."—J. P. Rees: Observations of Temperature and Moisture in Deep Coal-mines.—Prof. H. Briggs: Characteristics of Outbursts of Gas in Mines.—H. C. Harrison: The Use and Distribution of Shale-dust in Mines. The following papers, which have already appeared in the Transactions, will be discussed:—A. E. Beet and A. E. Findley: The Better Utilisation of Coking Slack.—J. I. Graham: The Normal Occurrence of Carbon Monoxide in Coal-mines.—T. L. Galloway: An Improved Method of Determining the Relative Directions of Two Reference-lines or Bases for Mining Surveys.—E. Bury, W. Broadbridge, and A. Hutchinson: Froth Flotation as Applied to the Washing of Industrial Coal.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital), at 4.30.—Dr. H. Head: Release of Function in the Nervous System.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Prof. C. S. Sherrington: Break-shock Reflexes and "Supramaximal" Contraction-response of Mammalian Nerve-muscle to Single-shock Stimuli.—R. J. Ludford and J. B. Gatenby: Dictyokinesis in Germ Cells, or the Distribution of the Golgi Apparatus during Cell Division.—Dr. F. W. Edridge-Green: The Effect of Red Fatigue on the White Equation.—E. Ponder: A Method for Investigating the Hæmolytic Activity of Chemical Substances.—W. H. Pearsall: The Development of Vegetation in the English Lakes, considered in Relation to the General Evolution of Glacial Lakes and Rock Basins.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—M. J. Conran: Curvature and Torsion in Elliptic Space.—J. L. S. Hatton: The Inscribed, Circumscribed, and Self-conjugate Polygons of Two Conics.—M. J. M. Hill: The Differential Equations of the First Order derivable from an Irreducible Algebraic Primitive.—F. S. Macaulay: Note on the Resultant of a Number of Polynomials of the Same Degree.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. F. L. Golla: The Objective Study of Neurosis (Croonian Lecture).

OPTICAL SOCIETY (at Imperial College of Science), at 7.30.—H. Lee: Achromatism.—W. L. Custance: Demonstration of the Société Genevoise Universal Measuring Machine.

FRIDAY, JUNE 10.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir George Seymour Curtis: The Development of Bombay.

ROYAL ASTRONOMICAL SOCIETY, at 5.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Sir Ernest Rutherford: The Stability of Atoms (Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. A. G. Webster: Absolute Measurements of Sound.

Co-operative Indexing of Periodical Literature.

THE selection, examination, and classification of the valuable matter contained in periodical literature is performed by two agencies, viz. certain abstracting and indexing societies and journals. "Science Abstracts" and the abstracts published by the chemical societies of England, France, Germany, and the United States are examples of the former class, while the "International Catalogue of Scientific Literature," the "Engineering Index," the "Index Medicus," the "Index to Legal Periodicals," and the various indexes published by the Anglo-American library associations represent the latter. Almost without exception, where the same field is covered by both types of publication, the two agencies work independently of each other. Further, in this country the publication of abstracts generally precedes the corresponding index publication, especially where the latter makes any pretence to completeness. This obviously is an indefensible arrangement; for the index material, which is the result of the wider survey, should be accessible to the abstractor prior to the preparation of the abstracts. We propose to indicate how this change could be accomplished with a minimum of disturbance to existing interests. It should be observed that the phrase "periodical literature" is used in its widest sense to include society publications and institutional reports, as well as annual, quarterly, monthly, and weekly publications.

The growth of periodical literature owing to the increased specialisation of knowledge is one of the most significant features of our times. A union catalogue of the current periodicals preserved in the German libraries, published in 1914, comprised some 17,000 entries. A similar list for the periodicals filed in the libraries of the United Kingdom, prepared in 1914–15 by some English State and Copyright librarians, was submitted for publication to the Department of Scientific and Industrial Research, but the proposal met with no encouragement. Yet the compilation of such a list is an essential preliminary to the proper national organisation of knowledge. For a union list indicates the relative strength and weakness of our national libraries in respect of their periodical collections: it enables the librarian to correct the latter without unduly increasing the expenditure of the library in that department of literature. Moreover, while primarily a time-saving expedient for locating the place of deposit of a periodical, it emphasises the essential unity of the library service in the satisfaction of the legitimate requirements of research. Our first proposal, therefore, is that representations should be made to the Trustees of the British Museum with the view of inducing them to undertake this necessary piece of national work. These representations would carry greater weight if accompanied by some guarantee of financial support. The work done in 1914–15, which is in the custody of the British Museum library authorities, would, of course, require considerable revision and extension, but the cost of its publication should not exceed 500*l.*—a portion of which would be recouped by its sale.

That a large proportion of periodical literature is of an extremely composite character is, of course, a commonplace; but the labour which this feature entails upon those responsible for the collection of material relevant to their particular fields of inquiry is not equally well realised. This composite character applies not only to the popular magazines and journals, but also to the repositories of original investigations in all branches of knowledge. The *Comptes rendus* of the Paris Academy, for example, furnish material not only for the seventeen sections of the "International Catalogue," but also for psychology, education, archæology, and technology. In the *Sitzungsberichte* of the Berlin Academy theories of relativity jostle with disquisitions on Hittite inscriptions and Turco-Tataric philology. In short, periodical literature may be said to consist of two classes: (*a*) watertight

Q

compartments containing homogeneous material, and (*b*) compartments which admit freely any literary matter of sufficient merit or popular appeal. The problem, therefore, is to devise a scheme by which information contained in the latter class—for class (*a*) presents no special difficulties—can be made to flow towards its proper recipient, and this, obviously, can be effected economically only by the acceptance of a common system of classification.

So far as the literature of science is concerned, a classification already exists in the scheme adopted by the "International Catalogue of Scientific Literature." This scheme has been incorporated in that of the Library of the United States Congress—a library the staff of which appears to possess special qualifications for dealing with the literature of the exact sciences. Further, this scheme has been published in two forms: (*a*) with its headings arranged in class order and issued in separate sections, *e.g.* Q = science in general [QA = mathematics, and so forth]; and (*b*) with its headings arranged in one general alphabet. Thus science possesses a classification stamped with its own hall-mark, but grafted on to a scheme for the general classification of knowledge. Still, the acceptance of the Library of Congress classification is not an essential feature of these proposals, which are based on the recognition (1) of the division of periodical literature into (*a*) the homogeneous and (*b*) the non-homogeneous classes; (2) of the economic advantage of dealing on a co-operative basis with the latter; and further, since the non-homogeneous periodicals cover all departments of knowledge, (3) of the necessity of adopting some agreed system of classification for the purpose of establishing a means of exchange between the different interests.

Thus we have shown that the core or *umbra* of a subject is comprised in a body of homogeneous literature which unquestionably can best be dealt with by its representative professional society, but that outside this core there exists a *penumbra* of relevant matter dispersed through a literature of gradually increasing irrelevance, with the result that the recovery of the relevant matter can be effected economically only by co-operative effort. The solution, therefore, would appear to be to bring into existence a Central Bureau which should deal solely with the indexing of periodicals of the non-homogeneous character—and in the first stages of its work, with a restricted list of periodicals assigned to it by the contributory bodies. These bodies would receive from the Central Bureau entries from the periodicals examined corresponding to their specified requirements. But as the professional abstracts became more fully representative of progress in their respective fields the need for the publication of the corresponding indexes would tend to disappear. The institution, therefore, of a Central Bureau would ultimately make for economy in all branches of science in which the publication of abstracts is admittedly indispensable.

So far as science is concerned, it will probably be found that the simplest and most effective method for obtaining the necessary index slips would be to invite the Central Bureau of the "International Catalogue of Scientific Literature" to provide them. Indeed, the possibility of co-operation between the "International Catalogue" and the abstracting journals was one of the subjects considered at the conference held last September. Any such arrangement would probably begin with the year 1921, and, as a preliminary, the "International Catalogue" should be brought up to date by the publication of volumes for 1915–20. The provision of funds for this purpose is an urgent necessity, as explained in NATURE for October 7, 1920, vol. cvi., p. 195.

In the foregoing observations we have assumed that the proper bibliographical equipment of the sciences will in the main be founded upon the possession of adequate abstracts. But if the subject were threshed out in an open conference at which representatives of all branches of knowledge were invited to attend, this proposition would not be accepted as holding good universally. Some branches would probably prefer periodical critical reviews or summaries of the year's progress, while others would be content with alphabetically arranged index entries. Our final proposal, therefore, is that such a conference should be held in order that the special requirements of each division of knowledge should be authoritatively ascertained, and the feasibility of co-operative or co-ordinated action discussed.

Piezo-chemistry.

Piezochemie kondensierter Systeme. By Prof. E. Cohen and Dr. W. Schut. Pp. ix + 449. (Leipzig: Akademische Verlagsgesellschaft m.b.H.: Gustav Fock, 1919.)

THE direction and extent of a physical or chemical change are frequently determined or modified by pressure. This fact has long been

known, and has been the subject of occasional investigation at various times, even from the earliest periods of systematic scientific inquiry. It occupied the attention of the first Italian academies, and was among the matters experimentally studied by the Fellows during the early years of the Royal Society. Until comparatively recent times, however, work on the subject was sporadic, intermittent, and directed mainly to the investigation of particular cases rather than to the elucidation of general principles. The necessities of modern chemical manufactures have created a demand for further and more accurate knowledge, inasmuch as the whole course of a chemical reaction and its economic aspect may depend upon it. Many instances of this fact might be cited. One of the most recent, and also one of the most striking, is seen in the case of the synthetic production of ammonia from its elements under the influence of catalysts, in which the question of the appropriate pressure is of fundamental importance.

Prof. Ernst Cohen, of the van't Hoff Laboratory of the University of Utrecht, and his collaborator, Dr. W. Schut, have placed chemists and physicists under a great obligation by their compilation of the book now under review. It does not profess to be a text-book on the subject. It is, as stated, a compilation of the facts known, or allowed to transpire, scattered through the volumes of some fifty different periodicals, and was originally made for the convenience of workers on the subject of piezo- (or pressure) chemistry in the laboratory which Prof. Cohen directs. The material thus accumulated has been arranged in a systematic and orderly manner. We have, first, a description of the methods of creating and measuring high pressures; next, a general discussion of compressibility, its methods, direct and indirect, with some account of their relative merits and defects. Then follows a full historical description of the several attempts to obtain accurate values of certain fiduciary constants generally necessary in piezometric work—viz. the compressibility coefficients of glass, mercury, water, and incidentally of ice, and their relation to temperature. Each section is accompanied by bibliographical references to the original sources of information.

The authors then treat of the compressibility coefficients of the various elements and such of their compounds as have been studied. Special attention is, of course, paid to the work of Richards, of Harvard, and his co-workers, and the question of the compressibility of atoms and the existence of interatomic spaces in solids and liquids is shortly discussed, mainly in the light of the American chemist's published views on the subject. As regards liquids, an attempt is made to group them in conformity with their chemical relationships. Thus all the hydrocarbons are brought together, as are the alcohols, esters, halogen compounds, acids, etc., obviously with the view of facilitating the detection of general principles. It must be confessed, however, that as yet the data afforded by different investigators are too discrepant to afford a satisfactory basis for generalisations. This is due mainly to imperfections in the method of observation, and in a less degree in some cases to insufficient care in the purification of the liquids employed. Accurate work, like that of Bridgman, suffers by association with that of earlier inquirers whose measurements were largely of the pioneering order.

Although definite numerical values are lacking in many cases, certain conclusions may be said to be fairly well established. Thus, for example, Bartoli has shown that the compressibility-coefficient in an homologous series of the liquid paraffins decreases with the increase of molecular weight. That the same is true of the aromatic hydrocarbons appears from the observations of Richards and his co-workers. Measured at equal temperatures and pressures, benzol is more compressible than toluol, and toluol than xylol. The various isomerides of xylol have, however, different compressibilities, *o*-xylol being less compressible than *m*-xylol, which in its turn is more compressible than *p*-xylol, and still less compressible than ethyl-benzol. Identical thermometric temperatures, strictly speaking, are not absolute evidence of a comparable physical condition. Before any sound deductions can be made it will be necessary to establish what is a valid comparable condition. There is a considerable volume of work on the compressibility of liquids, but its treatment and discussion are vitiated by the circumstance that this point has hitherto been insufficiently appreciated. For a fuller account of the relation of compressibility to the chemical nature and constitution of liquids, Prof. Cohen's volume must be consulted.

The influence of pressure upon the expansion-coefficients of substances—solids, liquids, solutions, and alloys—and upon surface tension and melting-point has been studied by many observers. Their work has been systematically collated by the authors, and its outcome discussed. The case of water is of special interest, on

account of the abnormality it displays in so many particulars. It is well known that the temperature of maximum density of water is lowered by pressure, a fact which was established by Tait in 1883, and, later, by Amagat, and confirmed on theoretical grounds by van der Waals and Puschl. Each increment of 1 atmosphere pressure lowers the temperature of maximum density by 0·0217° C. The influence of pressure on the melting-point of ice is equally well known, and has been frequently studied since it was first pointed out by James Thomson and his brother, Lord Kelvin, in 1849, and its natural effect traced by Faraday and Tyndall in the phenomenon of regelation and the movement of glaciers. The large body of evidence on the relation of pressure to melting-point has been carefully collected and displayed in tabular form. For its discussion we must refer to the work itself.

A considerable section of the work is devoted to a consideration of the influence of pressure upon the flow and permanent increase of density of solid substances, and upon the viscosity of liquids. As regards water, the viscosity diminishes with increasing pressure up to 900 atmospheres, between 0° and 32° C., when it attains a minimum. Above this temperature it increases by pressure; below it it decreases in proportion to the increase of pressure. All the phenomena of the compressibility of water serve to confirm the general belief that it is an associated liquid —*i.e.* its molecular complexity under ordinary natural conditions is not properly represented by the simple formula H_2O.

Space will not permit of more than the briefest possible reference to the remaining sections of this valuable work. These treat of the influence of pressure on the electric conductivity of solutions and solids; on the thermo-electric properties of metals; on dielectric constants; on the validity of Faraday's first law; on solubility, diffusion, refractive index, and polarimetry.

It will be seen from this account that the work is mainly concerned with the influence of pressure upon the physical properties of substances, and to that extent its title is rather a misnomer. It might, perhaps, be more fittingly styled piezophysics. However, the border-line between physics and chemistry is becoming more and more ill-defined, for the spheres of the two sciences gradually merge into each other. There is some point in the good-natured gibe that chemistry, after all, is only the dirty part of physics. We may, however, express the hope that the authors will add to our obligation by extending their work so as to include the influence of pressure upon chemical change. There is now a fairly abundant literature upon the subject, but it requires to be collected, annotated, and digested, and its general principles elucidated.

T. E. Thorpe.

Social Degeneration.

(1) *Social Decay and Regeneration.* By R. Austin Freeman. With an introduction by Havelock Ellis. Pp. xx+345. (London: Constable and Co., Ltd., 1921.) 18*s*.

(2) *The History of Social Development.* By Dr. F. Müller-Lyer. Translated by Elizabeth Coote Lake and H. A. Lake. With an introduction by Prof. L. T. Hobhouse and Prof. E. J. Urwick. (Studies in Economics and Political Science.) Pp. 362. (London: George Allen and Unwin, Ltd., 1920.) 18*s*. net.

(1) SAMUEL BUTLER tells us that the Erewhonians destroyed all their machines and lived happily ever after. An Erewhonian financier pointed to the "magnificent ruins of the railway-station" as an object of interest in his park. Mr. Austin Freeman, in all seriousness, agrees with the Erewhonians. His book is a searching indictment of the machine as the cause of our present discontents.

> Ill fares the land, to hastening ills a prey,
> Where wealth accumulates and men decay.

The decay wrought by machinery is not numerical; it is something much worse. The ultimate factor of national decline is racial deterioration; and in modern societies this is very extensive and pernicious. Unfavourable variations are not eliminated, and there is a reversed natural selection in favour of the unfit. The essential character of modern civilisation is a war of mechanism on man.

"Mechanism has destroyed industry and replaced it by mere labour; it has degraded and vulgarised the works of man; it has destroyed social unity and replaced it by social disintegration and class antagonism to an extent which directly threatens civilisation; it has injuriously affected the structural type of society by developing its organisation at the expense of the individual; it has endowed the inferior man with political power which he employs to the common disadvantage by creating political institutions of a socially destructive type; and finally, by its reactions on the activities of war, it constitutes an agent for the wholesale physical destruction of man and his works and the extinction of human culture. It is thus strictly analogous to those anti-bodies by

which the existence of aggregates of the lower organisms is brought to an end."

These charges are driven home in the most forcible manner. The old craftsman, who made a pair of boots and enjoyed his work, has been displaced by a crowd of factory hands, not one of whom could make a pair of boots, and whose work is irksome drudgery. By absorption into an organised aggregate the workman has become functionally atrophied; he has undergone degeneration. The working class is composed of men of a low average intelligence, in adjustment to the relatively small demands for intelligence made by the conditions of machine production. "That the working class consists largely of men of very slight skill was clearly shown during the war, when so-called 'skilled' men were called up for service and were easily replaced by admittedly unskilled men, or even by shop-girls and domestic servants." Machinery has changed a skilled into an unskilled population. The crew of the *Mayflower* could have established a civilised community; a modern company of factory hands and the like, who are normally parasitic on some machine, would starve on an uninhabited island, or relapse into complete barbarism.

Mr. Freeman has some criticisms, as true as they are scathing, on the component parts of our society. "Mere learning or scholarship, unaccompanied by additions to the sum of existing knowledge, furnishes no evidence of faculty above the level of mediocrity." "The professional politician whom democracy has brought into existence differs entirely from other professional men. He is totally unqualified. Such knowledge as the old parliamentary hand has acquired has no relation to social phenomena. It is purely egoistic." Our Government is as absurd as if medical and surgical knowledge were cultivated only by detached savants, while medical treatment was conducted and surgical operations were performed by strenuous but unlearned "men of action." The First Lord of the Admiralty may be a publisher, a brewer, or a stockbroker. Now that Government control is being extended in every direction, the system is disastrous, and has already produced social, economic, and industrial chaos. Our elaborate technical education, instead of training artists and craftsmen, produces only art-school masters and mistresses and technical-school teachers. The trade unions "have made no effort to regain liberty for their members as free workers or collective owners; though the money spent on a great strike would be sufficient to establish co-operative works on an extensive scale." The manual workers are becoming frankly anti-social as well as anti-democratic. Their activities are directed, not against the employers, but against the community. "The working man tends to be a bad citizen." He plots "to starve the country into submission; to treat his fellow-citizens as a somewhat uncivilised invading army would treat an enemy population." "The profound lack of the most rudimentary ethical conceptions which underlies these anti-social actions becomes manifest when we contrast the implied standard of conduct with that of the more intelligent classes." We cannot imagine the medical profession striking for larger fees in the midst of an epidemic. The bulk of the men no doubt do not realise that they are committing a crime against their fellow-citizens; but this only proves the very low quality of their intelligence. "The sub-man is usually a radically bad citizen."

Society, in a word, is disintegrating. Parasitism, the curse of humanity, is becoming almost universal. "The manual labourer has long since ceased to support himself completely"; "he has obviously arrived at the belief that he has a definite lien on the property of his fellows." The industrious and intelligent—"the only class that matters"—are being taxed and bullied out of existence.

Mr. Freeman has perhaps not allowed quite enough for the power of a body politic, when attacked by disease, to generate anti-toxins to resist the invasion. But though his pessimism may seem too unqualified, the justice of his strictures can scarcely be denied. His remedy, however, is not practicable. It is the "voluntary segregation of the fit"; the establishment of self-contained communities of skilled craftsmen and others, who would help each other to live a wholesome and happy life. Such a community might well be founded in a new country—in Western Canada, Southern Chile, Tasmania, or Rhodesia; the experiment would be well worth making; but in this country the new community would not escape ruinous taxation for the benefit of incapables outside, and would, moreover, be attacked and destroyed by the trade unions.

(2) Dr. Müller-Lyer's book is as typically pre-war as Mr. Freeman's is post-war. It rests throughout on the assumptions of evolutionary optimism. Civilisation *must* be progressing towards a higher state. The author seems to be an admirer of Marx, for he repeats the false statement, so often refuted, that the course of industrialism has tended to make the rich richer and the poor poorer. The presuppositions of the book vitiate its argument, but it contains many

interesting facts and reflections, and, unlike English Socialists, the author sees clearly that the unchecked increase of population is the most fatal obstacle to social amelioration.

W. R. Inge.

X-rays in Medical Practice.

General Practice and X-rays. By Alice V. Knox. With chapters on the production of X-rays and instrumentation by Dr. R. Knox. (The Edinburgh Medical Series.) Pp. xiv + 214 + xxxii plates. (London: A. and C. Black, Ltd., 1921.) 15*s*. net.

In view of the great advance which has occurred in radiography and radiotherapy during the past ten years, the author is justified in her contention that the time has come to present to medical practitioners a general survey of the subject in order to enable them to gain a full appreciation of the value of X-rays in diagnosis and treatment. The author divides medical practitioners into three groups: (1) Those who look upon X-rays as something of a scientific plaything; (2) those who rely upon radiology to establish a diagnosis instead of making a careful physical examination; (3) those who recognise in the new science a powerful help in the daily fight against disease, to be applied after a thorough physical examination has been made, when it may be of the greatest use in establishing a diagnosis or in treatment.

When X-rays were first discovered, certain applications to medical diagnosis were at once obvious. These included the discovery and location of metallic foreign bodies, and the diagnosis of fractures and other injuries of the bones. As a natural corollary came the use of X-rays in the study of disease of the bones and joints. With improvement in the construction of apparatus, and with advance in technique, it was found possible to extend the uses of X-rays to the diagnosis of certain internal disorders, such as calculi in the kidneys, and disease of the lungs, heart, and aorta.

The most noteworthy advance of all dates from the discovery that insoluble opaque salts can be administered to patients in sufficient amount to fill the gullet, the stomach, and the intestines, and so enable these hollow organs to be studied. Not only are their size, shape, and position revealed by the opaque meal, but also their contractile activities can be studied. In this way many valuable additions have been made to our knowledge of the physiology and pathology of the organs of digestion. With this far-reaching addition to the uses of X-rays there remain few organs or parts of the body which are not accessible to investigation by them, with good prospect of settling a doubtful diagnosis. If this were all, it would be clear that no medical man could afford to dispense with the services of radiology in the practice of his profession; but X-rays have done a great deal more than this. They have revealed the fact—previously suspected by few—that all disorders of the digestive tract are interdependent: that the stomach, for instance, does not become the subject of a gastric ulcer if all other parts of the digestive tract are healthy, and that the appendix does not become diseased so long as it is in a healthy environment.

Text-books on medicine arrange all diseases under the headings of the various organs of the body. Each organ has a chapter to itself, and each disorder of this organ occupies a "water-tight compartment." For teaching purposes this arrangement, no doubt, has advantages, but it also has the great disadvantage of perpetuating the notion that a chronic disease can arise in an organ of a patient who is otherwise in perfect health. X-ray investigation of the digestive system has demonstrated the fallacy of this conception of disease; it has led to a wide recognition of the importance of "chronic intestinal stasis," a condition due to abnormal delay of the intestinal contents, setting up bacterial decomposition and leading to contamination of the blood-stream. The result of this "toxæmia" is that every tissue of the body receives vitiated blood and becomes depreciated, so that it loses some of its power of repelling the invasion of microbes. Many chronic ailments, such as rheumatism, arise in this way and resist all efforts to cure until the contamination of the intestinal contents has been rectified. The stretching of ligaments, which gives rise to spinal curvature, flat foot, etc., is likewise due to the toxæmia of chronic intestinal stasis. The far-reaching importance of this new conception is clear, for in prescribing remedial exercises to strengthen the muscles of the back, or those of the foot and leg, it is important to attend to the general nutrition of the patient and to the efficient drainage of the intestinal canal, for muscles that are depreciated by contaminated blood cannot respond to attempts to strengthen them by exercises, massage, or electrical treatment, although such treatment would certainly strengthen healthy muscles.

These are only a few instances of the way in which the radiological study of the digestive tract is modifying our entire conception of the causes and treatment of disease.

Our Bookshelf.

Report of the Proceedings of the Third Entomological Meeting held at Pusa on the 3rd to 15th February, 1919. Edited by T. Bainbrigge Fletcher. (In three volumes.) Vol. i., pp. xii+417+69 plates. Vol. ii., pp. vi+418–835+70–129 plates. Vol. iii., pp. vi+836–1137+130–182 plates. (Calcutta: Superintendent Government Printing, India, 1920.) Rs.17 8 annas (3 vols.).

THIS bulky report is a record of thirteen days' deliberations given to the discussion of almost every aspect of entomology which is likely to concern the Indian Empire. During the congress ninety-two papers were read, and these are printed in the three volumes before us, together with a verbatim report of the discussions which were the outcome of these papers. A good deal of the information has already been published elsewhere, but it is doubtless convenient to have it gathered together and made available within the compass of a single publication. It is gratifying to note that the meetings were attended by forty-six professional entomologists and other officials, a fact which indicates the importance which this aspect of zoology has attained in the East. It is also pleasing to find an instance where a Government Department has been sufficiently generous to allow the publication of so detailed and profusely illustrated a series of volumes during these times of financial stress.

The greater number of the papers directly concern the economic entomologist, and perhaps the two most important are those entitled "Borers in Sugar Cane, Rice, etc.," and "Stored Grain Pests," which are written conjointly by Messrs. T. B. Fletcher and C. C. Ghosh. The last-mentioned paper might well be read by all interested in the reports of the Grain Pests Committee of the Royal Society. A paper by Capt. F. de Mello on "The Trichonymphid Parasites of Some Indian Termites" is of general biological interest, and the author brings to light several new forms of these remarkable Protozoa. Major Fraser writes on certain night-flying dragonflies—a habit scarcely suspected among such insects. Mr. A. W. Slater contributes a paper on the preparation and reproduction of scientific illustrations, and Mr. C. F. C. Beeson details a method of subject-indexing entomological literature. These few examples fail to do any justice to the wealth of information embodied in this report, but they will perhaps serve to indicate the wide range of subjects which came up for discussion. The volumes are clearly printed and illustrated, and reflect great credit upon all concerned in their production.

A. D. IMMS.

Instinct in Man: A Contribution to the Psychology of Education. By Dr. J. Drever. Second edition. Pp. x+293. (Cambridge: At the University Press, 1921.) 10*s*. 6*d*. net.

DR. DREVER'S important book on "Instinct in Man," which was reviewed in NATURE of January 31, 1918, is enriched in this second edition with an appendix which will be read with great interest by all who have followed the controversy over the nature of the human instincts and their relation to the emotions. The chapter is entitled "The Emotional Phase of Affective Experience."

There are two divergent views concerning the place the instincts occupy in the psychology of man, though the facts are not in dispute. What is in question is rather a principle of classification, which at times may seem no more than a matter of nomenclature. According to one view, the human instincts are a kind of action-patterns, or it may be chains of actions, automatically or even mechanically set in motion, similar in nature to the nest-building instincts of birds. In this view the human instincts are few in number, most of them probably vestiges, and all comparatively unimportant; but the affective or emotional side of experience becomes important. This is not limited to specific responses, but built up into "sentiments," which are affective systems and the foundations of human character.

The other view is that the whole basis of human experience is instinctive, and that the instincts are distinguishable and may be enumerated; but they are not partial and intermittent; rather they are pervasive and comprehensive. Each instinct is bound up with a specific emotion and only functions in connection with it, and these primary emotions, with their instincts, are practically constitutive of human nature.

Between these two views Dr. Drever does not exactly steer a middle course—he is too original to be content with that—but he does in his criticism try to conserve what is valuable in each and reject what is untenable.

H. W. C.

Energétique Générale. By Dr. Félix Michaud. Pp. vii+229. (Paris: Gauthier-Villars et Cie, 1921.) 10 francs.

"ENERGETICS" deals with the relations between the various forms of energy according to a uniform plan. Each form is assumed to be representable as a product of two factors—an "extensity" or "capacity" (x), and an "intensity" (X), related by the equation $\partial U/\partial x = X$. In the case of heat the extensity is the entropy, Q/T, and the intensity the temperature, T. General laws are then reached connecting U, X, and x.

The problems considered in the present treatise are most varied; they include mechanics, electricity, heat, and chemistry. The applications of the general principles are very clearly and elegantly presented, and the treatment, which is mathematical, is strictly logical. The question arises as to whether thermodynamics, which is a branch of "energetics," according to the exponents of the latter, is best considered in this somewhat formal manner. Boltzmann and Planck have emphasised the essential distinction between heat and the other forms of energy, but the theory of probabilities seems to have no place in the scheme of "energetics."

Phenomena of "Intelligence" in the Protozoa.

I REGRET to observe the spirit of the letter in which Mr. Dunkerly (NATURE, May 26, p. 395) replies to Mr. Ludford, though, as being primarily responsible for the statement of the theory suggested, and periodically referred to of late years, I fully realise how extremely careful one should be in the choice of words in conducting the discussion. There is probably no theory occupying the attention of zoologists in connection with which the motto of the Royal Society, "Nullius in verba," applies with greater force. Unfortunately, the "journalistic instinct" of many writers on scientific subjects has led them to credit observers with views which they have—to put it mildly—not yet reached, and to saddle them with responsibilities which they have never assumed. For instance, in Prof. Boycott's letter on the same page he credits my friend Earland with my views on "the selective intelligence of the Foraminifera," which is the one subject upon which my esteemed collaborator does *not* entirely agree with me.

The term "gregarious instinct" used by Mr. Ludford is an unfortunate one. The "grouping" of Protozoa to which he refers must be considered with a cautious appreciation of the elements of (*a*) fear, (*b*) reflex action, and (*c*) surface tension, but the most indignant opponent of my views will scarcely deny that the sense of fear is perhaps the most elementary phenomenon dependent upon a sensory system. It is, no doubt, related to, but it must not be confounded with, the "intelligence" displayed by many arenaceous Foraminifera in building their tests of *adventitious* material, and in using that material in such a manner as to protect the surface of the test from naturally incidental dangers of damage, and to protect the apertures of the tests against the entrance of predatory parasites.

The "grouping" to which Mr. Ludford directs attention must not be confounded with the associations of marine Rhizopoda, which gain protection against suffocation in soft muds by the co-operative use of spicules, arranged as catamaran spars to maintain them upon the surface (as in *Psammosphaera rustica*, H.-A. and E.), or with the aggregation of simple arenaceous tests for purposes of strength and protection, which, unfortunately, has led some of the earlier rhizopodists to treat such associations as new genera or species. It is as if they were to describe a litter of little pigs huddled together for warmth (which is an elementary phenomenon of intelligence) as a new and "polythalamous" genus of pig.

EDWARD HERON-ALLEN.

Large Acres, Selsey, May 31.

An Algebraical Identity $4X=Y^2-37Z^2$.

THE following is a well-known theorem derived from the theory of numbers. Let p be any ordinary odd prime, and let $X=(x^p-1)/(x-1)$; then there is an algebraical identity

$$4X=Y^2 \pm pZ^2,$$

where Y, Z are polynomials of degree $\frac{1}{2}(p-1)$ and $\frac{1}{2}(p-3)$ respectively; and the sign of the ambiguity is $+$ or $-$ according as p is of the form $4n+3$ or $4n+1$. The cases up to $p=31$ inclusive have been published; the result for $p=37$ has just been communicated to me by Pundit Oudh Upadhyaya, research scholar of the University of Calcutta. He finds that

$$4X=Y^2-37Z^2$$

with

$$\begin{aligned} Y=\;&2x^{18}+x^{17}+10x^{16}-4x^{15}+15x^{14}-5x^{13}+17x^{12}-8x^{11}\\ &+11x^{10}-4x^9+11x^8-8x^7+17x^6-5x^5+15x^4-4x^3\\ &+10x^2+x+2.\\ Z=\;&x^{17}+0x^{16}+2x^{15}-x^{14}+3x^{13}-x^{12}+2x^{11}-x^{10}\\ &+2x^9-x^8+2x^7-x^6+3x^5-x^4+2x^3+0x^2+x. \end{aligned}$$

I have tested this result in various ways, and have no reason to doubt its correctness.

It should be noted that Y may be obtained by expanding $2(x-1)^{18}$, and reducing the coefficients to their absolutely least residues mod. 37. It would be interesting to know the least value of p for which this rule does not apply. It must be less than 61.

G. B. MATHEWS.

7 Menai View, Bangor, May 29.

Atmospheric Refraction.

THE following proposition regarding the effects of refraction may be known, but I do not remember to have seen it stated. It is: "The course of a nearly horizontal ray of light in the lower part of the atmosphere is a circular arc having a radius of 14,900 geographical miles."

The velocity of light in that lower part of the atmosphere for which the decrease of pressure with the increase of height is nearly linear is given by the relation

$$v_h=v_0\left(1-a\frac{H-h}{H}\right),$$

where v_0 is the velocity *in vacuo*, v_h the velocity at the height h above the ground, and H the height of

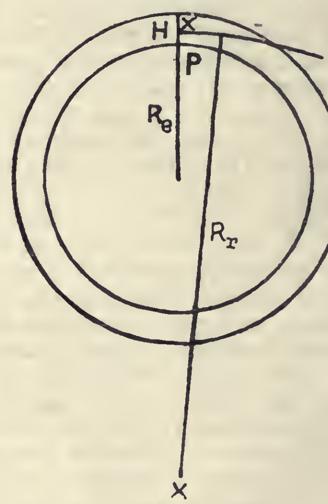

FIG. 1.

the homogeneous atmosphere ($a=00029$ nearly). At ground level the velocity is $v_0(1-a)$.

Let a plane vertical wave surface start from P as in Fig. 1. After the lapse of the time t it will have advanced v_0t at the height H, and $v_0(1-a)t$ at the surface of the ground. (This assumes the linearity of the relations between v_h and h to hold up to H, and though this is not true, the conclusions drawn from the assumption are correct, at any rate up to a few thousand feet.)

Thus at the time t the wave surface will be inclined forward, making an angle

$$\frac{v_0-v_0(1-a)}{H}t, \text{ or } v_0t\frac{a}{H},$$

with the surface at P. Since this angle is directly proportional to the distance between the two wave surfaces, the normal at any point—that is, the direction of the ray—varies at a constant rate, and is therefore the arc of a circle. If $v_0 t = x$ and R_r is the radius of this circle (which may be called the refractive radius),

$$R_r x \frac{a}{H} = x, \text{ so that } R_r = \frac{H}{a}.$$

In geographical miles $H = 4{\cdot}32$ about, which makes

$$R_r = 14{,}900 \text{ miles.}$$

The course of the ray is the same as it would be if it passed through an infinite number of vertically placed acute prisms of height H, having a refractive index $\mu_0/(1-a)$, with their bases occupying the whole surface of the ground. Since for horizontal rays these prisms are in the position of minimum deviation, rays which are pointed a few degrees up or down will still be arcs of the circle with 14,900 miles radius. The usual tables for the distance of the sea horizon assume that the horizon is x miles distant, when the height of the eye $(h) = \frac{x^2}{2}\frac{1}{R_e}$, R_e being the earth's radius.

If refraction is taken into account,

$$h = \frac{x^2}{2}\left(\frac{1}{R_e} - \frac{1}{R_r}\right),$$

or, in numbers, without refraction,

$$h = 0{\cdot}87\, x^2\,;$$

with refraction allowed for,

$$h = 0{\cdot}67\, x^2.$$

Thus the sea horizon viewed from a height h, or a mountain of this height just visible from sea-level, is a good deal further off than the ordinary tables would indicate.

If an atmosphere of the same height and density as that of the earth covered a globe of 14,900 miles radius, an elevation at any one point of its surface would be visible from every other point, and a light at one end of a diameter would appear to an observer at the other end as a bright line extending round the whole of his horizon. A. MALLOCK.

9 Baring Crescent, Exeter, May 12.

Young's Interference Experiment and the Spectrometer.

IN NATURE of April 28, p. 268, Dr. R. A. Houstoun directs attention to the use of the spectrometer for Young's double-slit experiment. In a letter on "The Visibility of Interference Fringes and the Double Slit" (NATURE, July 26, 1917, vol. xcix., p. 424) the present writer made reference to a similar optical arrangement. In that letter emphasis was laid, not on the advantages of the method for observing fringes and evaluating wave-length, but on its use for studying the changes in the visibility of fringes which occur as the width of the spectrometer slit is altered. In view of Prof. Michelson's recent use of the double slit for the measurement of the angular width of distant stars, I may be pardoned for directing attention to my note of some years ago, and for pointing out the ease with which an experiment similar in method to that of Prof. Michelson may be performed by means of an ordinary spectrometer. It is true that, instead of using a source of fixed (but finite) width and a variable double slit, the converse arrangement was employed, but in principle the methods are identical. It might be worth while, however, to vary the experiment by replacing the spectrometer slit by a small circular aperture and using a double slit of variable width.

May I also point out that the spectrometer may be used advantageously for an experiment on the limit of resolution of a telescope? It will be recalled that in the standard experiment a distant piece of gauze of fairly large mesh is viewed through a telescope before the objective of which an aperture is gradually narrowed until one set of wires disappears. If the slit of the collimator of a spectrometer be removed and in its place a piece of gauze of fine mesh be substituted, a much more convenient arrangement is available. During the past winter I found that students make quantitative measurements with such an arrangement without even darkening the laboratory.

In conclusion, it is well to note that for much of the above work even a spectrometer is not necessary. A telescope, a good lens, and adjustable slits are the only essentials. JOHN K. ROBERTSON.

Queen's University, Kingston, Canada, May 12.

The Reparation Act and Scientific Research.

THE columns of NATURE could, no doubt, be crowded with complaints concerning the Reparation Act, but as a sufferer I may be permitted to give the following instance of the extraordinary way in which this Act is used to hinder research.

I ordered a case of chemicals from Germany for myself and other workers in the Biochemical Laboratory, Cambridge, on February 2. In order that these should not come under the Reparation Act, they were dispatched on March 24 and arrived on April 8. Although the Reparation Act did not come into force until April 15, the goods were seized at Grimsby, and after a week's delay I was asked for all the original documents showing that the goods were ordered before March 8 and delivered before April 15. These were at once sent to London, but no reply was received from the Customs until I was forced to request the Medical Research Council, for whose work the chemicals were required, to apply to the Customs to free the goods as soon as possible. After three weeks' delay I received a letter from the Customs saying that the original documents were insufficient, and that a statutory declaration was required to confirm the particulars and to prove that the contract had not been fulfilled. This necessitated two visits to a commissioner of oaths and the preparation of a lengthy manuscript document adorned with red seals, the cost of which I have still to discover. This evidence was forwarded to the Customs a fortnight ago, and I have received no answer. The goods are still at Grimsby, the work of several people is being delayed, and the goods will apparently remain impounded (although they never came under the Act) unless I am prepared to submit to what might almost be called blackmail. To obtain the chemicals I must pay the full 50 per cent. myself, the funds of the Medical Research Council being unavailable for the purpose, and I must trust to recover the money from the Customs when my claim has been recognised—evidently a very doubtful eventuality.

All this delay, the expense, including the commissioners of oaths, not to speak of the worry and waste of time of an interminable correspondence, are apparently due to nothing but the red tape of a Government office. H. ONSLOW.

May 27.

British Laboratory Ware and Chemicals.

THE question of the quality, supply, and prices of British laboratory glassware, porcelain, and chemicals, including research chemicals, is under consideration by a committee of the British Science Guild. The

committee, the chairman of which is Sir Richard Gregory, is anxious, in view of the conflicting statements which have appeared from time to time on these matters, to obtain the views of scientific workers who have experience of recent articles of the kind described, both of British and foreign manufacture. It is obvious that the information can be of use only when it applies to goods of definitely known origin. The points on which information is desired are:—The quality of the goods; their price as compared with that of imported articles of the same quality; the facilities for obtaining supplies; and the effects, if any, on research work of restrictions imposed on the importation of German goods. The committee would also welcome statements made, or reasoned conclusions arrived at, by competent bodies who have investigated these questions recently, and from manufacturers who wish to add any further definite information to that which has already appeared in the Press. The information should be sent to the secretaries of the committee, Prof. J. R. Partington, East London College, or Mr. C. L. Bryant, 23 Peterborough Road, Harrow, as soon as possible.

J. R. PARTINGTON.
C. L. BRYANT.

Science and Technology in Palestine.

IN a lucid article, "Water-Power of Jordan," which appeared in the *Times* of May 18 the twofold scheme of the Jewish engineer, Mr. Rutenberg, was explained. Mr. Rutenberg proposes, first, to establish a barrage at the southern end of the Sea of Galilee to be used as the main power-house for the general purpose of electrification. Secondly, the malaria-breeding marshes of Lake Huleh are to be drained and a power-house constructed which will utilise the fall of the Jordan between Lake Huleh and the Sea of Galilee for power generation.

Readers of NATURE may be interested in a few further details of these plans. The latest calculations value the total potential water-power of Palestine at 1,000,000 h.p., *plus* a water-supply which will suffice to irrigate 1,200,000 acres of land. There is, of course, no intention of generating electricity to the full extent of this power; *e.g.* the proposed power station on the lower part of the Jordan, capable of generating 100,000 h.p. in twenty-four hours, would be sufficient to electrify the already existing railways of Palestine—which would need approximately 30,000,000 kw.h. per annum—as well as to supply the present general needs of Palestine. This station would also produce about 200,000,000 cubic yards of water for irrigation purposes; the installation would probably cost about 2,000,000*l*.

It is not necessary to emphasise the value of such schemes, both as regards increased fertility and productivity of the land, and in their effects on the social and economic life of the country.

In view of the local need for scientific knowledge, particular attention has to be paid to the Scientific Department which is to form the nucleus of the proposed University of Jerusalem. Already in 1913 Dr. Weizmann and the University Committee (whose chief scientific adviser was the late Prof. Paul Ehrlich) decided that research institutes should be founded, to be transformed as soon as possible into complete teaching faculties. Institutes of physics, chemistry, and microbiology were included in the initial scheme. It is hoped that through these institutes opportunity will be given for the solution of practical problems by Jewish experts on the spot. Obviously, from a practical point of view, it is better that Jewish talent should be utilised locally in this way, and from a wider point of view the University in its humanitarian as well as in its scientific aspects will form an integral part of the national life. DAISY L. ADLER.

The Zionist Organisation, 77 Great Russell Street, London, W.C.1, May 20.

Foreign Scientific Literature.

PROF. GARDINER in NATURE of May 19, p. 359, writes of the difficulty of obtaining Continental publications, whilst the complaint from Central Europe is all about the difficulty of getting English scientific literature. Perhaps something can be done by exchange. There are probably readers of *Die Naturwissenschaften* and of the *Elektrotechnische Zeitschrift* willing and eager to exchange with NATURE and the *Electrician*. Second-hand books with pages cut and owners' names inscribed would probably follow the analogy of worn clothes and be exempt from the interest of Customs officials. A year ago the Swiss bookshops in Berne seemed to carry a heavy stock of recent German scientific literature. Travellers returning from the Alps may wish to inspect these. For exchange of transactions of learned societies the mediation of the Anglo-American Library (hon. secretary, Mr. B. M. Headicar, School of Economics, Clare Street, London, W.C.2) might be invoked.

HUGH RICHARDSON.

Stocksfield-on-Tyne, May 26.

Flint Implements in the Cromer Forest Bed.

SINCE the reading of my paper on the humanly fashioned flints found upon the foreshore at Cromer before the Royal Anthropological Institute on May 3, I have again visited the Norfolk coast. This visit, in company with my friend Mr. Frank Barclay, of Cromer (who has recently collected close upon one thousand specimens of the ochreous artefacts from the foreshore), has resulted in the discovery of two flints, exhibiting the now well-known yellow coloration, *in situ* in the surface of the ferruginous "pan" or Stone Bed resting upon the chalk, and exposed, I conclude recently, at the base of the cliff above the beach deposits under Beeston Hills at Sheringham. This ferruginous deposit is of extreme hardness, and the two ochreous flints discovered could be dislodged only with great difficulty. There is, therefore, no doubt of any kind that the specimens form part of the deposit in which they occurred, which, without question, passes in under the very lofty cliff present at this spot.

Mr. Clement Reid ("Pliocene Deposits of Britain," p. 155) regarded the "pan" and Stone Bed at Sheringham as of Weybourne Crag age, and I think that, speaking generally, this opinion is correct. The two flints which have now been found were embedded in the surface of the Stone Bed, associated with a number of examples of clay pebbles such as occur in the lowermost strata of the Cromer Forest Bed deposits, and seem, therefore, to be referable to the horizon mentioned by me (NATURE, February 10, 1921) as that to which the Cromer artefacts might, in all probability, belong.

I have now found that the ochreous flint implements and flakes occur upon the foreshore exposed at low water at Sheringham and West and East Runton, as well as at Cromer, though they are much more numerous at the latter place. The peculiar form and technique of the specimens from all the sites mentioned are almost precisely similar, and I entertain no doubt that they may all be referred to one and the same "industry." The two flints now discovered, to which this letter especially relates,

are not large, and have attached to portions of their surfaces the very hard ferruginous matrix in which they were embedded. The larger specimen is a roughly shaped flint such as are found in some quantity at Cromer. The yellow-stained surfaces are typical, and exhibit the well-marked band of black unchanged flint under the layer of cortex. The other specimen is a small flake, with bulb of percussion, radiating fissures, and *éraillure,* and shows similar characteristics to the last-described flint, together with a whitish coloration on the bulbar surface, which is encroached upon extensively by the ochreous staining. This discovery establishes the fact of the occurrence at Sheringham of ochreous flints, comparable in every respect with many found at Cromer, *in situ* in the surface of the sub-Crag Stone Bed. It is established also that artefacts of the same order are to be found scattered among the large flints resting upon the chalk, and exposed at low water immediately opposite to the section in the cliff where the two flints were found *in situ.* There would seem, therefore, to be little doubt that the Cromer specimens are referable to the same horizon as those discovered at Sheringham, namely, the basal layer of the Cromer Forest Bed deposits.

In my paper read before the Royal Anthropological Institute I record the finding, at the Cromer site, of a large, yellow-stained flake exhibiting a mass of ferruginous "pan" material firmly adherent to a portion of its surface. This ferruginous deposit appears to be, in all respects, similar to that in which the two Sheringham flints were embedded, and its presence upon this flake supports the conclusion above stated as to the geological age of the Cromer artefacts.

The Physical Status of "Space."

It does not appear from Dr. Jeffreys's letter in Nature of May 26, p. 394, that we are at variance about anything really vital. What I do contend is this: that, thanks to the searching character of the theory of relativity, the time has come when it is profitable to attempt a much-needed unification of fundamental terms and conceptions, particularly in face of the curious indifference to such matters shown by some of those physicists who, with consummate skill, have developed the differential equations representing the natural forces. As the space of Nature is limited, may I briefly, in a series of categories, amplify my previous letters (April 7 and 21 and May 5), stating the case for the extension theory suggestively, but in no way dogmatically?

(1) If you objectify the pure spatial co-ordinate system of the mathematician you are of necessity dealing with attributes of some entity which, speaking within the limitations of human experience, must be supposed to answer to the designation "physical." I press for no other use of the term "æther," and this only as a safeguard against language suggestive of nothingness or absolute emptiness.

(2) The validity of the logical step (1) is supported by the theory of relativity, particularly the generalised theory, which actually affirms that the only objective space of human experience is physical space—out of which basis of experience the mathematician constructs his subjective spaces and pure geometries (in Dr. Jeffreys's sense of the word) representing various ideal, or possible, universes.

(3) The whole trend of twentieth-century physics is to teach us to think in terms of energy, not in those of matter. Matter is to be regarded as so much bound energy, as symbolised, indeed, in Einstein's expression, mc^2, for the energy equivalent of mass. It seems legitimate, therefore, to infer that the attribute of extension or extendedness ultimately belongs to energy.

(4) In the light of (1), (2), and (3), I submit that a desirable unification of ideas can be effected, and much confusion of thought avoided, if, instead of regarding the universe as *containing* energy, we regard it as *being* energy. Let the physical universe be defined as an evolutionary system of energy—that is to say, as an extensive entity the very nature of which is to express itself in changes and transformations (motions). This definition would render Comdr. McHardy's artifice of "container" and "content" (Nature, May 19, p. 360) unreal; and I cannot see that the distinction he makes is ontologically sound. Furthermore, does not the picture of the universe herewith presented throw into relief the necessary association of time with space, and illustrate that physical difference which leads us to regard time as *imaginary* space?

Finally, I would like to refer to the passage in Sir Oliver Lodge's article (Nature, February 17, p. 800) wherein he speaks of the necessity of "diving down into the æther." The metaphor is literally pregnant with meaning. It suggests, indeed, that when we shall have peered into the untold depths of the mere nameless *thing*—call it "space," "æther," "world," "metric," "substratum"—which is the scene of such momentous phenomena as light transmission and gravitational potential, it will prove to be a veritable mine of energy and a truly formidable physical reality. The great "æther" controversy seems now nearly spent, and I think it could be settled to-day if only the "non-ætherites" would frankly acknowledge that the world-energy is *continuous,* and the "ætherites" would think of their entity as an energy *continuum* rather than as functioning as a kind of independent luminiferous medium.

May 29.

The Colours of Primroses.

In view of the turn given to this discussion by Dr. Heslop Harrison's letter in Nature of May 19, it may be worth while to state that in the Island of Sark twenty-four years ago, in addition to an abundance of normal primroses, there were also plenty of (*a*) white, (*b*) pink, and (*c*) red flowers. Necessarily there can have been no appreciable difference of altitude.

Occasionally we find red primroses hereabouts, but my impression is—although I will not venture to write positively—that they do not run to the deep red of the Sark specimens. I remember finding one plant on the edge of a field three miles east of Polperro at an altitude of possibly 200 ft. or so.

I feel fairly certain that I never saw any cowslips in Sark—and I explored the island fairly thoroughly.

Gold-coloured Teeth of Sheep.

During the early part of the war the transport of sheep about the country districts was strictly regulated so that a local butcher could state definitely in which locality his meat had been fed. I noticed a large number of sheep's teeth encrusted with bright yellow tartar, identical in appearance with good average bright non-arsenical iron pyrites. I was assured that the sheep were fed upon Rye Marshes. I have a number of these jaws, and I should be pleased to send specimens to any museum interested in them or to anyone who would undertake to publish a full analysis and report upon the material.

W. J. Lewis Abbott.

Prehistoric Art in Caves and Rock-shelters.

By M. C. Burkitt.

PREHISTORIC art is a branch of prehistoric archæology or prehistory, and, as a study, is comparatively new. Although the discovery of the Altamira paintings was made many years ago, their palæolithic age was not accepted until after Rivière's discoveries at La Mouthe (Dordogne). Rivière, in the course of digging out the Magdalenian deposits of this cave, discovered an entrance leading to a long passage behind. The entrance had been completely obstructed by undisturbed layers of the deposit. Man could only have entered the inner cave previous to the deposition of these datable layers. In the cave behind were found a number of engravings, many of them quite primitive, and a few paintings. Once the palæolithic age of these drawings was accepted, M. Piette recalled the then almost forgotten paintings of Altamira. The fact that animals like the bison were found painted there (*i.e.* animals long ago extinct in Spain) further vindicated their palæolithic age, and any stray sceptic was finally won over by M. Cartailhac, when he published his famous retractation.

Since the beginning of the present century a very great deal of work has been done and further discoveries have been made in this fascinating study of early art. Not only do all the recognised text-books on prehistory devote considerable space to this early art, but also a number of books dealing specially with the art itself have appeared. These profess to cover the whole development of the art from its first appearance until early historical or even later times. The specialist, however, generally finds that there is a certain lack of balance in books of this type, which is by no means the fault of their authors, but simply due to the fact that a very large amount of material, especially of Neolithic or Eneolithic age, has not yet been published. Practically all the work on prehistoric rock drawings or paintings has been due to the Abbé Breuil (professor at the Institute of Human Palæontology, Paris). All the drawings that we see in the popular books are reproductions from his tracings of the originals. But besides these there are a great number which he has not yet had time to prepare for publication. The present writer, who is a pupil of Prof. Breuil, and has travelled with him in Spain and elsewhere, has neither the space here nor the right to anticipate his future publications, but perhaps a general survey of the rock drawings and paintings from Palæolithic to Bronze-age times may not be out of place, as well as a brief account of some of the more important recently published discoveries that have been made.

The prehistoric art in Western Europe that is to be found emblazoning the walls of caves and rock shelters, etc., can be divided into six groups:—

1. The ordinary Upper Palæolithic cave paintings and engravings.
2. The Eastern Spanish style, rock shelter paintings of Upper Palæolithic age.
3. The Spanish third group rock shelter paintings of Neolithic and Eneolithic age.
4. The Western Scandinavian rock carvings and paintings of Late Neolithic and Eneolithic age.
5. The South Swedish Bronze-age group of rock carvings, with an outlier on the shores of Lake Onĕga, North Russia.
6. The group of rock carvings, probably of Bronze age, that occurs high up on the flanks of Monte Bego, etc., in the Maritime Alps.

It may be well to discuss briefly each of these groups.

Group 1. The distribution of the ordinary Upper Palæolithic cave art depends first of all on the presence of suitable natural caves. This in turn demands the presence of limestone formations in the district. Secondly, it depends on whether the prehistoric tribes of the region employed this particular form of magic ritual to ensure a good success in hunting. These suitable conditions are found:—

(i) In Dordogne (France), especially concentrated round the little village Les Eyzies, on the River Vézère, some miles above where it falls into the River Dordogne.

(ii) In the Pyrenees, especially concentrated, so far as it is at present known, in the Ariège and adjacent departments.

(iii) In Cantabria and Asturias, North Spain, *i.e.* north of the Cordillera Cantabrica, that chain of mountains which forms a continuation of the Pyrenees along the north coast of Spain. Geographically, this region is South France rather than North Spain. The cave art here is specially concentrated near the town of Santander, which forms a good centre for visiting the caves.

(iv) A small series found in caves in South Spain. There is no doubt of the similarity of the art of this series and of the rest, but the apparent absence of the Upper Palæolithic cultures over the intervening Iberian Peninsula makes the actual connection rather obscure.

(v) In a single cave in the extreme south of Italy.

A proof of the age of this group has already been adduced, and there are others into which we need not go here. They would seem to have been executed for magical purposes, and this is shown from the following considerations:—

(*a*) The animals are often painted or engraved one on the top of another haphazard, which would not be the case if they were made for decoration.

(*b*) They are found in deep caves and often in obscure spots, difficult of access. At Niaux (Ariège) they are not found until the explorer

has penetrated half a mile into the hill. Man did not live in deep, dank caves requiring artificial light; his habitation was made under overhanging rocks on the sunny side of the valley, or occasionally in the mouth of a cave. These cave drawings, then, were not home decorations, and one could scarcely imagine a prehistoric man rushing half a mile into a hill with a blazing brand to light him in order to paint an animal in some narrow crack from mere *joie de vivre*. The only other explanation is that this art was used for some form of magic or ritual ceremonial. When we recall that the animals sometimes show arrows in their flanks, and when we find the human hand depicted (in one cave at any rate, mutilated by certain joints of the fingers being removed), not to speak of the presence of a number of queer signs at the meaning of which we can only guess, we are forced back to the conclusion that sympathetic magic is the sole explanation. A good catch is all-important to a hunting people, and no doubt these paintings and engravings, that are so lifelike in appearance, were used to further this object.

All the drawings are not of the same age, and they can be divided into a number of phases of different ages. These phases are determined by a careful consideration of the various styles that are painted or engraved one over the other. When such a palimpsest occurs, the engraving or painting on the top is obviously newer than those underneath. When a number of caves in the various regions are examined it is found that the succession of the styles is the same, whether we are in Cantabria, in the Pyrenees, or in Dordogne. Of course, certain local styles make their appearance in various places, but the main succession is the same. Detailed studies have enabled us to assign dates to these various styles, and we can now confidently affirm that phase 1 is Aurignacian; phase 2, Lower Magdalenian; phase 3, Middle to Upper Magdalenian; and phase 4, Upper Magdalenian. Certain geometrical figures of even a later date are sometimes placed in a fifth phase. The fact that the succession of styles is the same over such a wide area indicates either schools of tradition for the medicine men or priestly caste—*i.e.* for those who did the magic in the caves—or, at any rate, a fairly close intercourse between the various regions. This is still more startling in the case of decorated bones from the deposits themselves, where we find similar peculiar geometric decorations from Cantabria to the Ukraine.

In a new and unpublished cave there is the painting of a sorcerer masked as a stag dominating a frieze of engraved animals.

Group 2. The Eastern Spanish style. This is thought to be of Upper Palæolithic age, for the following reasons: (*a*) There is a painting of a bison at Cogul; of an elk at Cueva del Queso; of a chamois at Tortosilla (chamois have long ago disappeared from the province of Albacete, South Spain); of an elk, a reindeer, and a rhinoceros at the newly discovered rock shelter of Minateda (Albacete). (*b*) The figures of horses painted in the Eastern Spanish group at Cantos de la Visera are exactly similar in technique to a small horse painted in red among the northern group 1 at Portel in the Pyrenees. This Eastern Spanish style is peculiar in that it is found, not in deep caves, but under rock shelters, that are, however, deep enough to protect the paintings from actual moisture, which would give rise to moss growth that would soon destroy the paintings. The climate of East Spain is neither rigorous nor damp, and there is no reason why these paintings, made with oxides of iron as pigments, should not have lasted until to-day. Another characteristic of this group is the number of human beings depicted, often armed with bows and arrows. The most important discoveries made in this group in recent years are: (*a*) The rock shelter of Cantos de la Visera; (*b*) the rock shelter of Minateda; (*c*) the rock shelters of the Barranco de Valltorta (province of Castellón). The first of these was

FIG. 1.—Panel in the second rock shelter at Cantos de la Visera (Albacete, S. Spain). Paintings in the Eastern Spanish group of horses, stags, bulls, etc.

discovered by the writer, and is of importance from the occurrence of horses, which have been compared with one at Portel (see above) (Fig. 1); also by the occurrence of two painted birds (a great variety at all times in Palæolithic art, and above all in the Eastern Spanish group).

Minateda is important from the great wealth of paintings found there, among which are animals long ago extinct in the region. There is also a battle scene of men fighting (Fig. 2). Prof. Breuil has been enabled, from a study of the superpositions of the paintings, to unravel a very large number of different styles. These do not seem, however, to indicate any very great difference in age, or, if they do, we have as yet no means of correlating them with deposits of Upper

FIG. 2.—Panel at the new rock shelter of Minateda (Albacete, S. Spain). It belongs to the Eastern Spanish style, which is of Upper Palæolithic age.

Palæolithic age, as the latter seem to be absent from East Spain.

The rock shelters of the Barranco de Valltorta are specially interesting for the number of painted human beings which they contain, exactly similar in style to those found in Bushman paintings. The resemblance is startling —in fact, a research student in ethnology at Cambridge, when shown pictures of these rock shelters without being told their provenance, turned away, saying, "Oh, yes, those are some more Bushman paintings." There are several hunting scenes depicted.

The object for which paintings of this Upper Palæolithic, Eastern Spanish group were made cannot be determined with the same degree of certainty as in the case of Palæolithic group 1; it is probable, however, that magic was at the bottom of it.

Group 3. The Spanish third group of Neolithic or Eneolithic age. This group comprises scores of rock shelters all over Spain. Examples are also found in East Spain alongside the older Spanish group 2. Where examples of both groups occur in the same rock shelter, the examples of the Spanish group 3 are always painted over, and are therefore newer than the Spanish group 2. The style is altogether different, whereas in the Spanish group 2 the animals at any rate are naturalistic, even if the human beings are more or less conventionalised. In Spanish group 3 there is no attempt at a naturalistic drawing at all; the animals are often similar to what a child of four would make, and even more simplified than this, while conventions for the human form are bewildering. For example, the human form is sometimes represented by a vertical line from which two pairs of oblique lines are drawn forming arms and legs, or by the painting of a sort of hour-glass, or by a circle with a vertical line drawn through it, or again by the letter "D" placed horizontally with a vertical line drawn from it and dividing it into two segments; an eye is often indicated in each of these segments; although these figures often seem but remotely to resemble a human form, a complete series from an unmistakable human being to the most conventionalised example can be made out.

This Spanish group 3 is widely distributed over Spain. In the south-west area limited by Cadiz, Gibraltar, and Bobadilla, there are more than sixty rock shelters decorated with this art. Further east there is a large group in the province of Almeria, with the little village of Velez Blanco as a centre. All along East Spain this art occurs, sometimes, as has been said, in the same rock shelters, with examples of the Spanish group 2. The Sierra Morena and its continuation towards Portugal contains numerous examples of this group, while further north, south-west of Salamanca, in the valley of Batuecas (mentioned by Borrow in his "Bible in Spain" as a weird place, full of queer legends), this Spanish group 3 art is found in conjunction with some small semi-naturalistic figures that are of rather earlier date.

As in the case of the Spanish group 2, this Neolithic or Eneolithic art is found painted on the walls of fairly shallow rock shelters. The shelter, however, must be sufficient to prevent the access of damp, which, by promoting the growth of moss, etc., would rapidly destroy the paintings.

Certain pots dug up from deposits, dated as being of Late Neolithic or of Eneolithic age, carry engravings of the human form, etc., conventionalised in the same way as those found in the rock shelter. Pots of this nature have been discovered by M. Siret and Don Féderico de Motos in the province of Almeria, while Dr. Obermaier has described the same kind of thing from near Madrid. The discovery of these engraved pots enables us to date

the similarly conventionalised drawings of this Spanish group 3. Further, there is a painting of a man armed with a sickle, and another with what must have been a metal hatchet. Stone hatchets are, however, also occasionally figured. Again, a painting of a man occurs at Peña Tú, conventionalised in the same way as some found carved on certain menhirs, etc.; and in another rock shelter there is a painting of a man leading an animal, which indicates that domestication of animals had been learnt.

FIG. 3.—Two groups of rock engravings on the shores of Lake Onēga (N. Russia). Probably of Bronze age.

The object for which they were made would seem to be rather different from that of the Palæolithic groups. It may be noted, first, that the animals are no longer naturalistic, and, secondly, that the human form is the commonest object figured. At the same time, these rock paintings were not made for decorative purposes, for in many cases they are painted in situations difficult of access and impossible as homes.

Two examples of this may be given. In the western region there is a small cave called Las Figuras. This takes the form of a short tunnel about 10 yards long which opens some 15 ft. up on the side of a precipice. From the entrance the tunnel slopes up so steeply that it is with difficulty one can avoid slipping back over the edge of the entrance. The walls and roof of the tunnel are covered with paintings, and there are no signs left in the cave walls that any wooden constructions had ever existed, such as would have been necessary if man had ever inhabited the tunnel. The position of Las Figuras, opening as it does on the side of a prominent bluff, jutting out into a wide valley, made it eminently suitable for some form of temple, but the ritual could no longer have been a simple, sympathetic magic to ensure a good catch of game. Was there an element of real religion, and were these drawings, although apparently not orientated one to another, of the nature of pictographic writing? The other example is near Velez Blanco, where there is a small rock shelter known as Gabal. It contains no paintings, but a niche over the entrance, reached to-day by a ladder, contains quite a number. Are these the sacred emblems of the household; a protecting *talisman* for the "Home" below?

Group 4. The Western Scandinavian engravings. This interesting group of rock carvings on hard, glacier-worn surfaces of rock is found fringing the western coast of Scandinavia from Narvik, in the north, to Vingen Fjord, in the south. Occasionally, when the mountains of the interior open out, they are to be found stretching back, even into Sweden. They consist of a number of carvings of semi-naturalistic animals, the best of which is the well-known reindeer at Böla. A few paintings of this age are also known, including some conventionalised human figures at Leka. Prof. Breuil has always considered that there is some connection in culture, if not in time, between the folk who made these carvings and the Maglemose civilisation of the Baltic areas. This group is certainly earlier than the next Bronze-age group, for at Bardal, near Trondhjem, the latter is found superposed upon it. On the other hand, it has been thought that the

FIG. 4.—Onēga (site B). A swan with wing feathers indicated.

rocks at Bardal were under the sea before *Allée Couverte* times. There may have been a cultural survival from the Maglemose civilisation, even if they are Late Neolithic in age. Is it possible that the new and interesting find of an engraved animal on a piece of crust at Grime's Graves is to be correlated with this group?

Group 5. Bronze-age rock carvings of South Scandinavia, with an outlier in North Russia. This group, which is especially concentrated in Bohuslain (north of Göteborg), is too well known to be discussed here further. It is dated from a consideration of the form of daggers figured, as well as from the carved ornamentation. Runes are never found in association with these rock carvings.

The North Russian outlier is of some interest, and will be partly described this year. The carvings are found here on extremely hard, glacier-worn surfaces of rock, forming the eastern shore of Lake Onĕga, south of Pudosh, and north of the Black River. There are ships, swans, a devil 10 ft. long, animals, a phallic scene, fish, signs, etc. (Figs. 3 and 4).

Group 6. Maritime Alps. This group is also too well known to require further discussion. The occurrence of a ploughing scene, very similar to one found in the Bronze-age group of South Scandinavia, may be noted.

Dark Nebulæ.

By Dr. A. C. D. Crommelin.

SEVERAL years ago photographs taken by Profs. E. E. Barnard and Max Wolf rendered the hypothesis highly probable that many of the dark lanes and spaces met with in the Galaxy and in regions of diffused nebulosity were due to the intervention of occulting matter rather than to actual diversity of star distribution. One of the most notable examples occurs in a long strip of nebulosity that runs southward from

Fig. 1.—Nebulosity south of ζ Orionis. From a photograph taken by Mr. Duncan with the 100-in. telescope of the Mount Wilson Observatory.

ζ Orionis. Dr. Isaac Roberts noted that there was "an embayment, free from nebulosity, dividing it into halves." Prof. Barnard afterwards remarked that this space appeared to be "a dark body, projected against, and breaking the continuity of, the brighter nebulosity." More recently still the object has been photographed at the Lick and Mount Wilson observatories. The Mount Wilson photograph, taken with the 100-in. Hooker telescope, is here reproduced, and is quite startling from the hard, clear-cut outlines of the marking, which is blacker than the neighbouring sky background. It would seem that this sharp outline must indicate a stratum of dust rather than one of gas; it can be traced for some distance outside the long nebula, and is probably connected with an isolated bright nebula some 15 minutes of arc distant to the north-east. It will be remembered that a great part of Orion is covered with faint nebulosity, first revealed as a large spiral by Prof. Barnard's photo-

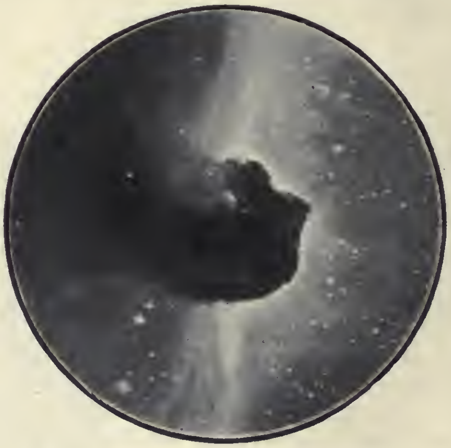

Fig. 2.—Enlargement of dark nebulosity in Fig. 1.

graphs with a lantern lens. There is a striking falling off of star-density to the east of the long ζ Orionis nebula as compared with that to the west, which presumably indicates a general absorption of light.

The Proceedings of the Amsterdam Academy of Science, vol. xxiii., No. 5, contains two papers by Dr. A. Pannekoek on a region of dark nebulosity in Taurus. Dr. Pannekoek refers to a paper by Sir F. W. Dyson and P. J. Melotte (M.N.R.A.S., vol. lxxx., p. 3). He uses their figures of star-density in these regions to make an estimate of

the distance of the occulting screen, and obtains the distance 140 parsecs, which is about four times that estimated for the Hyades. Since the angular extent is 30°, this implies a real length of 70 parsecs, and gives a vivid idea of its gigantic dimensions.

Dr. Pannekoek next proceeds to make an estimate of the mass of the nebula; he first works on the assumption that it is composed of hydrogen. The star-counts indicate an absorption of two magnitudes. Using Dr. Abbot's absorption coefficient for atmospheric air, and taking the thickness of the stratum as 10 parsecs, he finds 10^{-15} for the density of the gas-cloud. The mass is independent of the thickness assumed, and comes out twenty thousand million times that of the sun. This is greater than many estimates of the combined mass of the whole sidereal system, and at once suggests the probability that the larger portion of that mass is not condensed into stars, but distributed in cosmic clouds. Some striking consequences of the presence of such a great mass at a comparatively moderate distance are drawn by Dr. Pannekoek. The sun would travel round it in a very eccentric ellipse in a period of some two million years, being now near apocentron.

While so large a mass of the universe as a whole would render it easier to account for the numerous cases of high velocity among the stars, it would make the moderate velocities of the bulk of the stars difficult to explain. The author notes a suggestion by Prof. De Sitter that the necessary mass of the occulting clouds may be greatly reduced if we postulate that they consist of dust instead of gas. It has already been pointed out that the aspect of the dark marking near ζ Orionis accords with the hypothesis of solid matter. However, even in this case the necessary mass is enormous, since it is *a priori* improbable that the thickness of the stratum should in all cases be a very small fraction of its visible dimensions.

The demonstration of the existence of these immensely massive cosmic clouds seems to make it desirable to rediscuss the dynamics of the stellar system.

Obituary.

Prof. E. B. Rosa.

The death, on May 17, of Prof. Edward Bennett Rosa, of the Bureau of Standards at Washington, at the age of sixty years, is a serious blow to electrical science. Born in 1861, Prof. Rosa gained distinction as a student in the Johns Hopkins University under Rowland, and after some experience in professorial work in the Wesleyan university where his early undergraduate days nad been passed was in 1901 appointed to the staff of the Bureau of Standards as a physicist. There his main work was done. In 1910 he became chief physicist, and as head of the electrical department was responsible for many of the valuable researches which have been carried out at the bureau.

Among the earliest of these was his determination, in collaboration with Dr. Dorey, of "v," the ratio of the electrical units, and most of them turn on questions relating to the measurement of the fundamental units, the ohm, the ampere, and the volt. He combined in a marked degree the insight required to design and carry through to a successful result a difficult experiment and the mathematical skill needed to develop to a high degree of accuracy the theory on which the experiment is based.

Prof. Rosa's papers on the calculation of coefficients of self- and neutral induction, and on the theory of the instruments employed in absolute measurements, will always be standard; while his own experimental determinations of some of the fundamental quantities are among the best which have been made. He realised the need for accuracy and exactness in the processes of measurement, whether applied to scientific work or to industry, and he organised the electrical section of the bureau in a manner which fitted it to respond to the requirements both of scientific and industrial research. The list of his papers covers a wide range, and in all of them he added to our knowledge in a substantial manner.

Prof. Rosa visited England in 1908, acting, along with Dr. Stratton and Prof. Carhart, as one of the American representatives to the International Electrical Conference, held in London under the presidency of the late Lord Rayleigh. At that conference a formal distinction was drawn between the absolute and the international units of measurement: between the ohm (10^7 absolute C.G.S. units) and the international ohm—the resistance at 0° C. of a uniform column of mercury weighing 14·521 grams, and 106·300 centimetres in length; or the ampere (10^{-1} absolute C.G.S. units) and the international ampere—the current which under certain carefully defined conditions deposits from a solution of nitrate of silver a mass of 1·11800 milligrams of silver per second.

Prof. Rosa would probably have preferred to retain as standards for legal purposes the absolute magnitudes 10^7 C.G.S. units for resistance and 10^{-1} C.G.S. units for current, but he accepted the views of the majority of the conference, and at a later date lent his valuable assistance in defining accurately the conditions necessary for the realisation of the international ohm, ampere, and volt. As the outcome of the work of the conference, a committee, known as Lord Rayleigh's Committee, was appointed to define these conditions, and representatives of England, France, and Germany met at Washington and carried out a series of experiments, the results of which have determined the practice of all National Standardising Laboratories. Of the

committee engaged in this work Prof. Rosa was the active head, and its successful issue was due in no small degree to his skill in overcoming the technical difficulties of the task and to his tact in dealing with the varied views of those engaged in the research.

The volume giving an account of these experiments, published by the Bureau of Standards in 1912, will form a fitting memorial of one who for the last twenty years devoted himself unweariedly to the advancement of electrical science. During the war he directed the development of a number of instruments of great use to the American forces in France. Among these may be mentioned a sound-ranging device and much radio apparatus suitable specially for aircraft. He was greatly instrumental in establishing the splendid radio laboratory at the bureau. Throughout his life he was keenly interested in the prevention of industrial accidents and in the provision of safety standards for the guidance of public authorities. The national electrical safety code at present in use in the United States owes much to him. His last work, now in the press, was an analysis of the expenditure of the Government Departments, which contains a number of statistics of great importance and interest.

Prof. Rosa was married in 1894, and Mrs. Rosa survives him; she has the deep sympathy of all those on this side of the Atlantic who knew her husband and appreciated his work.

Miss Czaplicka's sudden death on May 20 cuts short a brilliant career. Having studied geography at Libau and Warsaw, she came with a research scholarship to this country in 1910, and soon after joined Somerville College, Oxford. She then turned her attention to anthropology, and, after taking the diploma in that subject, conceived the bold project of an expedition to the almost unknown part of the Siberian *tundra* lying between the Yenisei and Lena valleys—a project that was carried out with brilliant success in the years 1914–15. It was in keeping with her spirit of thoroughness, however, that by way of preparation she should first review the existing literature, mostly Russian, relating to this region, thus producing "Aboriginal Siberia" (Clarendon Press, 1914), a book not only full of out-of-the-way information, but likewise showing interpretative power of a high order. Her return from an adventurous journey involving great privations was marked by the appearance in 1916 of a popular work, "My Siberian Year"; but the full report by herself and her colleague, Mr. H. Hall, of the University of Pennsylvania, has not yet been published. At Oxford Miss Czaplicka acted as lecturer in ethnology until the end of the war, when she passed on to the University of Bristol to serve in a like capacity under Prof. Fawcett. In the meantime she found time to compose a valuable monograph on "The Turks of Central Asia," as well as to contribute many articles on the Siberian tribes to Hastings's "Dictionary of Religion and Ethics"—articles which might well be reprinted together in book-form. This brief account must suffice of the work of one whose intellectual energy was on a par with her personal charm and lofty spirit of self-devotion. Poland, so prolific of genius, can count her among its best. In Oxford, London, and Bristol alike she was the centre of a circle of admiring friends, whose lasting regret it now is that they did not somehow prevent the too courageous spirit from fatally overtaxing the delicate frame.

R. R. M.

We regret to announce the death, on May 31, of Col. John Herschel, R.E., retired, F.R.S., youngest son of the late Sir J. F. W. Herschel, Bart., in his eighty-fourth year.

Notes.

The list of honours conferred on the occasion of the King's birthday includes the following names of men known to the world of science:—*Knights:* Prof. Arthur Keith, Hunterian professor and conservator of the Royal College of Surgeons; Dr. T. Lewis, hon. consulting physician since April, 1918, to the Ministry of Pensions; Dr. S. Russell-Wells, Vice-Chancellor of the University of London; Dr. F. Conway Dwyer, ex-president of the College of Surgeons, Ireland; Mr. J. B. Harrison, Director and Government Analyst, Department of Science and Agriculture, British Guiana; and Brig.-Gen. D. J. McGavin, Director-General of Medical Services in New Zealand. *C.B.:* Mr. Ll. S. Lloyd, Assistant Secretary to the Department of Scientific and Industrial Research. *K.C.I.E.:* Col. W. H. Willcox, late Medical Adviser to the Civil Administration in Mesopotamia. *C.I.E.:* Dr. M. N. Banerjee, Principal of Carmichael Medical College, Belgatchia, Bengal. *Companion Imperial Service Order:* Mr. G. J. Williams, Senior Inspector of Mines, Mines Department.

An interesting ceremony took place at the Cosmos Club in Washington on Tuesday, May 10, when Mr. Henry S. Wellcome presented Dr. F. B. Power with a gold medal, specially struck to commemorate the latter's tenure of the directorship of the Wellcome Chemical Research Laboratories in London from their foundation in 1896 to 1914, when for family reasons he returned to the United States. During that period more than 170 papers were published from the laboratories, mostly in the Transactions of the Chemical Society. These papers deal chiefly with the constituents of plants, more especially with those plants used in medicine, and they form a notable contribution to our knowledge of the chemistry of drugs of vegetable origin. It will be remembered that in 1913 Dr. Power received the Hanbury medal, which is bestowed periodically by a joint committee of the Chemical, Linnean, and Pharmaceutical Societies in recognition of specially meritorious research on drugs.

A discovery in the Channel Islands of considerable interest to archæologists is announced in the *Times*

of May 31. Mr. L. M'Lellan Mann, of Glasgow, has found on the surface of a rock at Green Island, Jersey, a series of shallow depressions or "cups." Similar cup-markings are found in Great Britain and on the Continent, and are widely distributed over other parts of the world, including India, Australia, and North America. Green Island, where these cups have been found, is an island at high tide only, and has been severed from the mainland in comparatively recent times. From previous discoveries it is known to have been the site of a Neolithic burial-place. This would be in agreement with the usual attribution of rock carvings, such as these in Jersey, to the Neolithic or early Bronze age. On the other hand, cup-marks with one or more concentric rings, which have a more restricted distribution and, with a few exceptions, are found only in the United Kingdom and Sweden, are usually more or less closely associated with remains of the Bronze age. It is stated that cup-markings have not hitherto been recorded from the Channel Islands. This, however, is an error. Sir J. Y. Simpson figured two cup-marked stones from Guernsey, one being the prop stone of a dolmen with eleven cups, the other a conical standing stone with three large cups placed at some distance apart (J. Y. Simpson, "Archaic Sculptures," Proc. Soc. Scot. Ant., 1864–65, plate viii., Figs. 2 and 3; see also C. Rau, "Observations on Cup-shaped and other Lapidarian Sculptures in the Old World," in "Contributions to North American Ethnology," vol. v., Washington, 1882, pp. 12–13). No cup-marked stones have, however, previously been recorded from Jersey.

THE Advisory Council for Scientific and Industrial Research has quite recently granted an application made to it to assist in carrying out a piece of research work relating to the determination of the parallaxes of stars having a certain type of spectrum. The grant has been made to Mr. W. B. Rimmer, who up to the present has been employed in spectroscopic researches at the Imperial College of Science and Technology under the direction of Prof. A. Fowler, but will now carry out this research at the Norman Lockyer Observatory at Salcombe Hill, Sidmouth. This observatory was founded by the late Sir Norman Lockyer in 1912, and the programme of work has been confined strictly to the photography of the spectra of stars and their subsequent classification according to his scheme of increasing and decreasing temperatures, which has been confirmed in its general features by the more recent work of Russell and Hertzsprung on giant and dwarf stars. The researches of Prof. W. S. Adams have now rendered it possible to differentiate almost at a glance between a giant and a dwarf star. As a large amount of spectroscopic material was available at the Norman Lockyer Observatory for the application of Adams's method a trial research was begun. The method is based on a connection found by Adams to exist between the true brightness of a star and the intensity of certain lines in its spectrum. These line-intensities were determined by him by estimation, the plates being examined under a spectro-comparator. At the Norman Lockyer Observatory the method employed is to cover the lines gradually with a dark wedge, the position of which when a line is obliterated indicates the intensity of the line. The results of this trial research have proved very satisfactory, and were commented upon very favourably by Prof. H. N. Russell on the occasion of a visit to the observatory. The above grant has been awarded to aid the extension of this research to all stars of suitable type down to declination $-10°$ and of magnitude 6·5 and brighter. It is very opportune, for the staff of the observatory is small, and the work could not have been undertaken without such additional help.

THE annual visitation of the National Physical Laboratory, Teddington, will be held on Tuesday, June 28, from 3 to 6 p.m.

THE Safeguarding of Industries Bill was read a second time in the House of Commons on Tuesday, June 7.

THE annual conversazione of the Institution of Electrical Engineers will be held at the Natural History Museum, South Kensington, on Thursday, June 30, from 8.30 to 11 p.m.

AT the meeting of the Physical Society of London on June 10, to be held at the Imperial College of Science, South Kensington, S.W.7, Sir Ernest Rutherford will deliver a lecture entitled "The Stability of Atoms."

PROF. EINSTEIN was expected to arrive at Manchester yesterday, and will deliver the Adamson lecture on "Relativity" at the University at 5.0 this afternoon, June 9, when the honorary degree of Doctor of Science will be conferred upon him. He will leave Manchester for London to-morrow morning, June 10.

MR. CHURCHILL announced at Manchester on Tuesday, June 7, that the Government has decided to devote the sum of 1,000,000*l.* to fostering cotton-growing in the British Empire. The money will be placed at the disposal of the British Empire Cotton Growing Corporation, and will be in place of the Government's former promise of 50,000*l.* a year for five years to the corporation.

THE Hugo Müller lecture of the Chemical Society, entitled "The Natural Photosynthetic Processes on Land and in Sea and Air, and their Relation to the Origin and Preservation of Life upon the Earth," will be delivered by Prof. Benjamin Moore on June 16 at 8 p.m. in the lecture hall of the Institution of Mechanical Engineers, Storey's Gate, Westminster, S.W.1.

AT a general meeting of members of the Royal Institution held on June 6 special thanks were given to Sir Humphry Davy Rolleston for his present of a safety-lamp which was in the possession of Dr. John Davy, brother of Sir Humphry Davy, and to Sir David L. Salomons for his present of a privately printed Life and Study of the Works of Breguet, the famous watchmaker, Arago's watch, and two others of special interest, the first working aneroid made by Vidi in 1857, and a series of models illustrating the development of the chick.

It is proposed to hold an additional ordinary meeting of the Royal Meteorological Society for the reading and discussion of papers in Edinburgh on September 7. The British Association will be in session in Edinburgh on September 7–14, and arrangements are being made to hold the society's meeting, probably in the afternoon, immediately before the work of the Association begins. The possibility of a "meteorological luncheon" and of an excursion of special meteorological interest is also under consideration.

THE Newcomen Society for the Study of the History of Engineering and Technology is one of our younger societies, having been founded only a year ago. The titular name adopted by the society is that of the eighteenth-century engineer to whose labours we owe the steam-engine as we know it to-day. The subject which the society takes for its field is one which has been too much neglected in the past, perhaps more so in this country than elsewhere, in spite of the fact that England has been the cradle of so many leading inventions. To some extent this indifference is caused by the fact that the materials needed by the historian in this branch of human endeavour are all too scanty, and it is the aim of the society to help in supplying this deficiency. Besides holding meetings, the society intends to help in the preservation of records, MSS., and drawings of engineering work, as well as of biographical matter concerning those who have been prominent in such work. It is also intended to publish at the end of each session a yearbook containing original papers and historical matter not readily accessible. The summer meeting will be held in Birmingham on June 16–17 (headquarters, Queen's College, Paradise Street), under the presidency of Mr. A. Titley, and visits to places of interest are arranged for both days. On the first day the president will give his address, and Mr. A. Seymour-Jones will read a paper on "The Invention of Roller Spinning." This is appropriate in view of the little-known fact that the first attempts in this direction were made in Birmingham. The hon. secretary of the society is Mr. H. W. Dickinson, and communications should be addressed to him at the Science Museum, South Kensington, S.W.7.

THE thirty-second congress and health exhibition of the Royal Sanitary Institute will be held on June 20–25 at Folkestone under the presidency of the Earl of Radnor. Some five hundred delegates have already been appointed to attend the meeting, representing Government Departments interested and health authorities of the British Isles, as well as delegates from Australia, New Zealand, Canada, France, and Denmark. The congress will be divided into five sections:—Section A (president, Sir Leslie Mackenzie) will deal with sanitary science and preventive medicine; Section B (president, Major W. H. Prescott) with engineering and architecture; Section C (president, Mrs. H. A. L. Fisher) with the hygiene of maternity and child welfare; Section D (president, Mrs. R. G. Wood) with personal and domestic hygiene; and Section E (president, Viscount Burnham) with industrial hygiene. Conferences have been arranged for medical officers of health, sanitary authorities, engineers and surveyors, veterinary inspectors, sanitary inspectors, health visitors, and rat officers. A long list of subjects for discussion has been published, among which are such important topics as the control of developmental and wasting diseases, the relation of hospitals to preventive medicine, tuberculosis, industrial fatigue and welfare, the prevention and destruction of rats, and smoke abatement. A popular lecture on June 23 by Prof. E. Mellanby on "Vitamins and their Relation to Health" has been arranged, and excursions will be made to places of interest in the neighbourhood of Folkestone. June 25 will be devoted to a whole-day visit to Boulogne, during which the members of the various sections will be conducted over appropriate institutes in the town. Further information on local arrangements can be obtained from the Secretary, the Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.1.

DR. CAPITAN and M. Peyrony have contributed to the *Revue Anthropologique* a *résumé* of the works of art which they have discovered at La Ferrassie. The specimens are now deposited in the museum of the Château des Eyzies. The engravings, etc., belong to an early phase of the Aurignacian period, and are among the most ancient works of art known to exist. One of the earliest, which the explorers themselves unearthed, is a human figure from which the head and limbs are absent and only the trunk remains. This is rudely shaped and by no means beautiful; it is not steatopygous. Deeply outlined carvings of horses' heads and deer's heads were found on rocks. All the figures are exceedingly rude. One stone is occupied with cup markings in concentric circles, and cups appear mingled with other designs. Two complete figures of deer in outline, coloured red and black respectively, were found. Another figure represents the head of a rhinoceros, but only one engraved human figure appears. The authors note that all the engraved figures were placed face downwards, except in one case which could not be so treated; this had been designedly mutilated. They hold that these rudimentary, yet already complicated, images are the earliest known artistic manifestations and are ritual representations of magical practices.

MISS NINA F. LAYARD has published an interesting account of her discovery of mammalian remains with Mousterian flint-implements in a Pleistocene clay in the Stoke railway cutting at Ipswich (Proc. Prehistoric Soc. East Anglia, vol. iii., part ii.). Besides well-preserved teeth and bones of the mammoth, horse, large ox, and red deer, there are remains of three individuals of a large lion and fragments of a large bear. There are no traces of the reindeer. Close to the crushed skull of a mammoth were found some characteristic pieces of the shell of the small freshwater tortoise, *Emys orbicularis*, which had not previously been observed in late Pleistocene deposits in England. Miss Layard desires to mention that all the fossils were named in the geological department of the British Museum (Natural History).

THE greater part of the skull and neck, with a nearly complete shoulder-girdle, of a new Plesiosaurian from the Wealden of Berwick, Sussex, has just been added to the exhibited series of fossil marine reptiles in the geological department of the British Museum (Natural History). The specimen was found in a hard nodule in the pit of the Cuckmere Brick and Tile Co., and was presented to the museum by the managing director, Mr. Stanley Tooth. It represents a small reptile, about 6 ft. in length, and is of great interest as probably being a freshwater species. Just as among existing Cetacea the river-dolphins are generally smaller than the marine porpoises, so among the extinct Plesiosauria the freshwater forms may have been smaller than those living in the sea. In the structure of its shoulder-girdle the new species resembles the early Jurassic Plesiosaurs more closely than those of later Jurassic times. It, therefore, seems to have been an out-of-date survivor preserved by such an isolated mode of life as a freshwater habit would allow. The shoulder-girdle is uncrushed, retaining its original shape, and showing that the reptile was round-bodied, not depressed like a turtle.

THE Rhodesia Museum, Bulawayo, being in urgent need of a new exhibition gallery, has been promised 1000*l*. by the Rhodes Trustees, and Sir Otto Beit has promised 250*l*., provided the sum of 750*l*. be subscribed by the public. By the end of 1920 486*l*. had been subscribed, and the museum committee now appeals for further donations.

WE are glad to see that the *Museums Journal* is not fulfilling its threat to appear only quarterly instead of monthly, though it has overcome a temporary difficulty by an April–May number. In this Dr. Hecht, of the Nancy museum, makes some suggestions for co-operation between French and British curators, which should bear fruit when the Museums Association meets in Paris next month. One is that examples of the rings attached to migrating birds should be shown in the museums of the Continent, so that visitors to them may become aware of their meaning.

THE report of the South African Museum for 1920 records the death of the old Seychelles tortoise known as "Peter." It proved to be a female. So long ago as 1834 she had reached a gigantic size, but how old she then was is not known. One of the Cape tortoises belonging to the museum had reached a great size in 1843, and still fulfils the objects of her sex. Among much other interesting matter in this report, Dr. Peringuey adduces fresh evidence that the stone querns of the Bushmen were not for grain, but were grinding mills for crushing ore. The craft of these African smiths, however, never enabled them to make so much as an iron hammer or to dispense with the use of stone implements.

THE Journal of the Royal Society of Arts for May 13 contains a paper by Sir James Cantlie describing Thomson's machine for armless men in whom the amputations are so high that it is impossible to fit artificial limbs. The apparatus consists of a table under which are pegs which are worked by the toes. These actuate rods and levers which communicate movements to rods above the table, which constitute artificial "arms" by means of which all kinds of instruments may be grasped and worked. The patient is thus able to use a spoon, knife, and fork, drink from a cup, pick up a cigarette from the table, place it in his mouth, open an ordinary box of matches, strike a match, and light the cigarette, write with pen or pencil, typewrite, turn over the leaves of a book, play draughts, wash and dry his face and neck, etc. The condition of the armless is indeed pitiable, and the inventor deserves the greatest commendation for the design and construction of this ingenious machine.

IN the Gardens' Bulletin, Straits Settlements (vol. ii., Nos. 9–11, 1921), Mr. T. F. Chipp publishes a list of the fungi of the Malay Peninsula, which it is hoped may facilitate the work of mycologists engaged on the study of plant diseases and lead to a more detailed systematic study of Malayan fungi.

SEVERAL papers dealing with the fungus flora of South Africa appear in the Transactions of the Royal Society of South Africa (vol. viii., part 4, 1920, and vol. ix., part 2, 1921). Miss Ethel Doidge contributes a revision of the native species of a family of moulds (Microthyriaceæ) which are abundant on the leaves of plants in humid wooded districts. Descriptions, and in many cases figures, are given of the species, a large proportion of which are new to science. In a second paper Miss Doidge describes in detail the method of attack and nutrition of the tropical genus Meliola, which occurs on shoots and leaves of forest trees and shrubs. The fungus is shown to be a true parasite, sending penetrating suckers through the epidermis of the host, blocking up the stomata, and causing considerable disorganisation of the cells. Mr. Paul van der Bijl describes for the first time a fungus (*Ovulariopsis papayae*) which attacks the pawpaw plant along the coast of Natal, forming a powdery covering on the under-face of the leaves.

THE Liverpool Geological Society has done well in publishing in its Proceedings (vol. xiii., part i., 1920) a translation, somewhat abbreviated, of Dr. A. Heim's paper "The Weight of Mountains." The original appeared in the Annual of the Swiss Alpine Club for 1918, and the illustrations are now reproduced. The map shows the variation of gravity throughout Switzerland from what is regarded as the normal value, and is based on results recently obtained with the seconds pendulum for a large number of localities. The measurements are recorded as if values below the normal were due to an excessive thickness of rock underlying the station with a specific gravity of 2·4, and curves are drawn representing these thicknesses at 100-metre intervals. Lines of normal gravity-effect (0) occur on the south side of the Black Forest and north of the Lago Maggiore. Between these regions the lines are approximately parallel with the strike of the Alpine folding, and the gravity-defect runs up to −1600 in the Engadine and to −1450 on the southern flank of the Rhône Valley near Visp. Dr. Heim regards the Alpine mass as floating, partially submerged, in a plastic "sima" underlayer, into which

it has sunk back to some extent since its maximum elevation in late Miocene times. There is thus beneath its surface a region of mass-defect, a "gravity-synclinal." The sheets of detritus from the early chain now dip towards their source, and the author once more urges that the lakes penetrating the foothills on either side are due to a reversal of the slope of primary valley floors. The paper thus presented to English readers is a clear and valuable addition to the literature of isostasy.

In the *Meteorological Magazine* for April a summary is given of the rainfall of San Domingo, dealing chiefly with the eastern half of the island. Meteorological data from the Dominican Republic are said to be extremely rare; the rainfall records discussed have been received by the Meteorological Office, and are roughly summarised by Mr. C. E. P. Brooks. The observations were forwarded by Mr. W. A. Elders, the general manager of the Samana and Santiago Railway, who since 1913 has had twelve rain-gauges installed. A map is given showing the annual average results for the twelve stations, which are situated along the valley of the Yuna River and its tributaries. Detailed monthly averages are given for Sanchez, on the border of Samana Bay, at the eastern extremity of the island, and for La Vega, situated near the centre of the island, about sixty miles westward from Sanchez. Results for Port au Prince, in the west of the island, are added for comparison. Over the eastern half of the island the heaviest rain occurs from May to August, and there is a subsidiary maximum in November. The driest months are from December to March. There is a considerable range in the annual rainfall. At Sanchez the average for the year is 71·09 in., ranging from 56·00 in. in 1918 to 81·52 in. in 1913; whilst at La Vega the average annual fall is 67·58 in., ranging from 41·28 in. in 1920 to 100·85 in. in 1917. The prevailing wind is from the east, distinctly a trade wind, trending somewhat from the south-east in the summer months and from the north-east in the winter months. The country is mountainous, but very fertile in the valleys.

At the April meeting of the Optical Society Mr. F. Twyman described an instrument for testing camera lenses. The method depends on interference, and permits of the measurement, in wave-lengths of the light used, of the deviation from sphericity of the whole of the wave-surface transmitted by a lens from a point source behind it. This is secured by mounting the lens under test so that it can be rotated about a line at right angles to its axis passing through its second principal point. The apparatus brings the beam which has traversed the lens into interference with one which has travelled a fixed distance, as in the case of a Michelson interferometer. The isochromatic lines of the interference pattern then correspond to equal deviations from sphericity of the transmitted wave surface. The instrument affords a most severe test, and defects of lenses by first-class makers have been found by its means.

The report of the council presented at the annual meeting of the Illuminating Engineering Society on May 31 contains evidence of further useful work, new joint committees in co-operation with various other bodies having been formed to study special problems arising from recent discussions. Amongst the subjects thus dealt with are photometry, motor-headlights, and the lighting of kinema studios. It is also remarked as gratifying that international co-operation in connection with illumination is being resumed. A session of the International Illumination Commission, the first since the outbreak of war, is being held in Paris in July, and such questions as motor-headlights, "artificial daylight," and regulations for industrial lighting will be discussed. Following the formal business at the annual meeting Mr. J. S. Dow read a paper on "The Use of Artificial Light as an Aid to various Games and Sports." An account of the lighting of various covered tennis courts was given, and it was suggested that even the artificial illumination of football and cricket grounds and golf links, though admittedly presenting considerable difficulties, might be accomplished in the future.

We have received from Messrs. C. Baker, High Holborn, a descriptive pamphlet of a universal geometric slide photomicrographic apparatus made by them from the design of Mr. J. E. Barnard and originally described by him in 1911. The base is designed on the girder principle to obtain rigidity, and the portion carrying the microscope is constructed to swing out so that the object may be searched. The camera, a half-plate one, has a 3-ft. extension. The upper surface of the base carries two parallel metal rods, and the camera slides on these by two **V**-grooves on one and a plane surface on the other, the latter being intermediate in position between the **V**-grooves. The principle of the geometric slide is thus obtained, the apparatus being supported practically on three points forming the apices of a triangle, while alignment is maintained by the **V**-grooves. It may be clamped down in any position, and by means of a spindle running in bearings along the centre of the casting, which actuates a pulley "belted" to the fine adjustment with a thin cord, focussing may be carried out at any position. All subsidiary apparatus, including the illuminant, is similarly carried on geometric slides. The price of the apparatus is 33*l*., or with arc lamp and some subsidiary apparatus about 40*l*.

The April issue of the *Whitehall Gazette* contains an interesting article on the fraudulent proceedings that were practised to avoid service when conscription was in force in this country. Some claimed exemption on the ground that they were suffering from consumption, but declined to provide sputum there and then, promising to send samples. The samples forwarded did contain tubercle bacilli, but they were dead, and the specimens were found to be artificial concoctions. A good many forged passports were produced by Russians who remained in this country. In some cases a passport belonging to another would have the written details bleached out by chemical means and the desired name, etc., inserted. Sometimes the date of birth of the man's own passport might be put back ten years. These forgeries were detected by the change in reflecting power of the surface of the paper caused by the removal of the size

by the bleaching agent or by the attempt to replace it, by the spreading of the ink caused by the removal of the size, by the restoration to visibility by chemical means of the bleached-out writings, by the finding of the bleached inscriptions by photography under suitably coloured lights, and so on. The article is illustrated with excellent photographs and reproductions of photographs.

ON May 10, at the Institute of Petroleum Technologists, Prof. P. Carmody (late Government analyst, Trinidad) read a paper on "Trinidad as a Key to the Origin of Petroleum." Prior to the meeting the title of the paper had created much interest and curiosity, especially among those members who have had professional experience in the island, but unfortunately both the paper and subsequent discussion were scientifically somewhat disappointing. The author's main contention was that in a comparatively small area, within reasonable access of Europe, and under conditions of life peculiarly satisfactory for a tropical island, there exist all the requisite natural factors for an exhaustive research into the origin of petroleum, as yet a little understood problem, the solution of which must perforce have far-reaching scientific and economic results. The natural factors referred to include the occurrence of varied forms of solid, liquid, and gaseous hydrocarbon compounds within the rocks of the island, and in illustration of his idea the author gave a brief description of these, supplemented with a large number of chemical and physical data obtained during the course of some thirty years' work in the Government laboratory. There is obvious value in the publication of such data by one whose long experience entitles him to speak with authority, but the *raison d'être* of the paper suffered much from the somewhat narrow view taken as to the origin of oil, viz. its derivation entirely from vegetable matter, *i.e.* cellulose. On this assumption, and in view of the many known oil occurrences wherein marine organisms have unquestionably been involved, it is doubtful whether Trinidad does indeed constitute the desired "key," and whether, as the president remarked later, the existence of all these forms of petroleum is not a disadvantage rather than an aid to the solution of the problem.

PROF. R. S. TROUP, of the forestry department of the University of Oxford, has written for publication by the Oxford University Press a work in three volumes on "The Silviculture of Indian Trees." The first volume, dealing with Dilleniaceæ to Leguminosæ—Papilionaceæ, is promised for appearance by an early date.

A FULL report of the meeting held on May 30 by the National Union of Scientific Workers on "The Administration of Scientific Work," of which a short account was given in last week's NATURE, p. 439, will appear in the next issue of the union's Journal. Copies may be obtained from the Secretary, N.U.S.W., 25 Victoria Street, S.W.1, at the end of this month (post free 6*d*.).

Our Astronomical Column.

COMETS.—Reid's comet is rapidly fading, but should be within reach of moderate instruments for another month. An extension of the ephemeris from Ebell's elements for Greenwich midnight is therefore given:

	R.A. h. m. s.	N. Decl. ° ′		R.A. h. m. s.	N. Decl. ° ′
June 9	8 8 33	51 38	June 29	8 17 41	43 31
13	8 10 41	49 35	July 3	8 19 16	42 21
17	8 12 37	47 48	7	8 20 49	41 18
21	8 14 24	46 13	11	8 22 19	40 19
25	8 16 3	44 48	15	8 23 46	39 24

Values of $\log r$, $\log \Delta$: June 13, 0·0665, 0·2311; June 25, 0·1054, 0·3035; July 7, 0·1459, 0·3543.

The following observation of Pons-Winnecke's comet was obtained at Greenwich: G.M.T. June 2d. 10h. 57m. 38s.; apparent right ascension, 20h. 37m. 15·85s.; apparent north declination, 37° 12′ 45·8″. The position deduced from Crawford and Levy's second elements is right ascension 20h. 38m. 5s., north declination 37° 3′. The elements are therefore fairly near the truth.

The comet now appears large and diffused owing to its small distance from the earth. It will be nearest to both earth and sun on June 12.

Mr. G. Merton obtained an observation of Dubiago's comet on June 1. He states that its position agreed closely with the ephemeris given in NATURE of May 26.

NOVA CYGNI III. (1920).—Mr. Denning writes that he observed this object on June 5 at 10h. 40m. G.M.T. with a 6½-in. refractor. He estimated the magnitude to be 9·6, so that the star's light would appear to have declined very slightly during the last 7½ months. It will be remembered that the magnitude of the star decreased from 1·8 to 8·5 during the 43 days from August 24 to October 6, 1920, so that the average decline of light was 0·16 per day. Since about the middle of October, however, the nova appears to have maintained its brightness in a rather unexpected way.

COLLISION OF STAR AND NEBULA.—Prof. Ernest W. Brown contributes a paper on this subject to the April issue of the *Astrophysical Journal.* Taking the star as origin and the line of relative motion as the Z-axis, particles of the nebula equidistant from this axis would all be deflected into similar hyperbolic orbits meeting in a point on the axis. There would thus be numerous collisions of particles along the axis which would generate a fan-shaped nebula with its apex towards the star. Another nebulous envelope surrounding the star would be formed by collisions of particles with the star or its appendages. The nebula is supposed to be non-gaseous at the start, being composed of widely scattered particles.

Hubble's variable nebula round the star R Monocerotis is discussed in detail, and it is shown that its form agrees closely with that indicated by the theory. It is suggested that the variations in the light of the fan-shaped appendage may arise from irregularities in the density of the nebula that the star is supposed to be traversing. It is shown that Prof. Slipher's observation that the stellar envelope and the fan-shaped appendage have identical spectra is in accord with the hypothesis, for both would arise from the gas resulting from collisions of the nebular particles. Slipher and Lampland's further statement that the spectra resemble those of novæ in their early stages suggests to Prof. Brown that a similar explanation may be available for the phenomena of novæ.

The Edinburgh Meeting of the British Association.

THE preliminary programme and invitation circular for the eighty-ninth annual meeting of the British Association, to be held in Edinburgh on September 7–14, is now ready for distribution. Members of the Association will receive it shortly if it has not already reached them; others who propose to attend the meeting may obtain a copy on application to the Assistant Secretary of the Association, Burlington House, London, W.1. The circular, which is more comprehensive than has been customary, contains more than a merely preliminary programme, for many of the definitive arrangements for the meeting are set forth and a time-table of the principal engagements is appended. The circular is a pamphlet of sixteen pages with a three-leaf cover. One leaf, detachable at a perforation, provides two reply forms—one for intimation of attendance and the other for intimation of the member's local address—and, in order to assist the organisation of the meeting, members who propose to be present are requested to complete and return these forms at their earliest convenience. On another cover is a useful map of central Edinburgh, on which are indicated the principal buildings, especially those to be used for the meetings, the railway stations, the 'bus and tram routes, and the principal hotels.

A prefatory note on Edinburgh is followed by the announcements regarding conditions of membership and railway communications. In the latter we note that the general officers of the Association have made, and will continue to make, every endeavour to secure a reduction of return fares for members attending the meeting, but up to the present they have been unable to obtain this concession from the railway authorities, and, failing the issue of a further intimation, it must be assumed that the concession formerly customary cannot be given this year. Enclosed in the circular is a printed slip directing attention to a proposal to run motor coaches from London (following routes *via* Oxford and Cambridge) and from Bristol, Liverpool, and other towns north of these, to convey members to Edinburgh, and back again if so desired. The fares would be approximately two-thirds of those charged by the railways in each case. The motor coaches would leave London and points south of Liverpool on September 5, completing the journey to Edinburgh in two days, and arrangements would be made for hotel accommodation *en route*. From Liverpool, Manchester, Leeds, and points north thereof the journey to Edinburgh would be made in one day—September 6. Passengers' luggage would be collected and delivered, each passenger being allowed 56 lb. free of charge. This enterprising project can be realised only if the transport company has a guarantee as to the number of members who would be prepared to avail themselves of it, and members are therefore requested to state on their intimation forms if they would make use of the motor service.

The programme gives the titles of the addresses, discourses, and principal discussions. The presidential address by Sir Edward Thorpe will deal with some aspects and problems of post-war science pure and applied. The evening discourses are on subjects especially appropriate to a meeting in Edinburgh. Prof. C. E. Inglis will make a comparison of the Forth and Quebec bridges, showing the evolution of cantilever-bridge construction during the past thirty years; and Prof. W. A. Herdman will give an account of the important part played by Edinburgh in the progress and development of the science of oceanography.

The sectional presidents' addresses will cover a wide range of subjects; for example, the laboratory of the living organism, the boundaries of physiology, experimental geology, evolution, the theory of descent in relation to the early history of plants, the study of native races, consciousness and the unconscious, the place of music in a liberal education, water-power, the principles by which wages are determined, and agricultural economics. Several of these addresses are to be introductory to discussions. The president of the Conference of Delegates of Corresponding Societies is to give an address, followed by a discussion, on "Science and Citizenship." Arrangements have been made for a number of joint sectional discussions, and the following are announced as the respective subjects: The structure of molecules, the age of the earth, biochemistry, the proposed mid-Scotland canal, the origin of the Scottish people, and vocational training and tests. The times of the sectional presidential addresses and of the principal discussions have been arranged so that those on cognate subjects are not held at the same hour; for instance, the addresses are distributed over the Thursday, Friday, and Monday mornings, and not more than two are at the same hour.

From this summary it will be evident that the arrangements for the meeting are in an advanced stage, and we understand that this is also the case in regard to the programme of papers to be presented to the various sections.

The forthcoming meeting in Edinburgh—restored to its pre-war length of a full week—promises to be one of great scientific interest and value, and all well-wishers of the Association are looking forward to a full resumption of the activity and influence of the Association.

The Royal Observatory, Greenwich.

THE visitation of the Royal Observatory took place on June 4, when the report of the Astronomer Royal, which covers the year ended on May 10, was presented. The report states that strenuous efforts are being made with the transit circle to complete the present catalogue, which embraces some two thousand stars of the list prepared by Dr. Backlund and Mr. Hough; the aim of that list was to obtain a convenient number of reference stars uniformly distributed over the sky. These observations will be concluded at the end of this year, after which observations will be commenced of all stars down to magnitude 8·0 between N. declination 32° and 64°. It will be remembered that stars down to magnitude 9·0 between declination 64° and 90°, and also between 24° and 32°, have recently been observed at Greenwich. The catalogue of the last-named region was distributed during 1920; it includes the determination of the proper motions of 12,000 stars.

The mean error of the longitude of the sun, as given in the Nautical Almanac, is $-1\frac{1}{2}''$; that of the moon is $-13''$, which is deduced from observations on 114 nights. Eight occultations of stars by the moon were observed, and also both phases of the solar eclipse of April 8.

The 28-in. equatorial has undergone extensive repairs by Messrs. Cooke; observations of double stars have now been resumed. The working catalogue

has been drawn up with the idea of avoiding overlapping of observation and of including stars the orbit determination of which is hopeful. Many orbits of binaries have recently been computed by Mr. Jackson, who has also, together with Mr. Furner, published an investigation showing that the mean mass of binary systems is double that of the sun. Working on this assumption, hypothetical parallaxes have been deduced for several hundreds of stars. The observations with the 28-in. equatorial since 1893 have been collected into a volume, which is nearly ready for publication; it also contains the orbits found by Mr. Jackson, and notes on the relative motion in cases where orbits cannot yet be determined.

The programme of parallax determination with the 26-in. equatorial is being continued. The plan of taking double exposures on the same plate at six-month intervals has been dropped; each plate is now developed after exposure. Fiducial plates of each field are prepared by making rulings with a diamond in the positions of the parallax star and reference stars; all the plates are compared in succession with the appropriate fiducial plate. Forty-nine parallaxes have thus been deduced in the year, the number of plates measured being 829; the probable error of a determination is 0·009″.

There are two extensive investigations in progress with the aid of diffraction gratings. The grating employed with the astrographic equatorial gives a first diffracted image 2·83 magnitudes fainter than the principal image. By successive steps it is possible to compare the magnitudes of all stars within the range of the instrument. The magnitudes of the stars in the Harvard polar sequence are being re-determined. The results obtained so far confirm the Harvard scale for the fainter stars, and the Mount Wilson one for the brighter.

The grating on the 30-in. reflector is being used to obtain the effective wave-length, and hence to infer the spectral type, of the stars in the Greenwich astrographic zone (declination 64° to 90°). An exposure of seven minutes suffices to give satisfactory results for stars of magnitude 10·5. Effective wave-lengths have already been determined for 550 stars within 3° of the Pole, the mean probable error being 10 angstroms.

The astrographic equatorial will shortly be dismounted in preparation for its removal to Christmas Island for next year's eclipse. Sir Howard Grubb and Sons are making an equatorial mounting for use there, as the cœlostat method proved unsatisfactory in 1919 for a problem involving such great precision as the investigation of the Einstein bending of light. Mr. Jones and Mr. Melotte will start for Christmas Island early next year, and remain six months on the island. The fact of having an astrographic equatorial close to the equator will be utilised for taking series of photographs for the purpose of comparing the magnitude scales of northern and southern zones.

The Reid and Pons-Winnecke comets have been observed both visually and photographically on several nights. The first photograph of the latter was secured within a few hours of the receipt of Prof. Barnard's telegram announcing his detection of the comet.

The usual magnetic and meteorological observations have been continued. The mean magnetic declination for 1920 was 14° 8·7′ W.; it is diminishing by 9½′ annually, which will bring it to zero about the close of the century. The chief magnetic disturbance was from March 22 to 25, 1920, being associated with a large group of sun-spots. The mean temperature for the first four months of 1921 was the highest for that period during the last eighty years, January being 7·5° above the average. The rainfall was 18·77 in., being 5·47 in. below the average of seventy-five years. July and September alone were above the average.

The Astronomer Royal refers to the success attained by Mr. Bowyer in the mechanical registration of wireless signals on a siphon recorder. Signals are received from the Eiffel Tower, Nauen, Annapolis, Darien, Bordeaux, and Lyons; some special series were sent from Lyons for the determination of Australian longitudes. These were recorded both at Greenwich and in Australia.

The Chinese Earthquake of December 16, 1920.

By DR. C. DAVISON.

A PRELIMINARY report on the destructive Chinese earthquake of December 16 last has been prepared by Father E. Gherzi, and is published by the Zi-ka-wei Observatory. Though brief, it is of considerable interest, as it is the first scientific account that we have received of this great earthquake. The report is based on the letters received from correspondents of the observatory (nearly all missionaries), on articles in Chinese and other newspapers, and on the seismograms provided by the Wiechert astatic pendulum (mass 1200 kg.) at the observatory.

The first shock registered there occurred on November 16, others on December 4, 6, and 10, and possibly three early on December 16. The primary waves of the great shock arrived on that day at 12h. 9m. 16s., and the secondary waves at 12h. 11m. 45s. In less than two minutes later one of the recording levers was dismounted, and after 3½ minutes more the other passed off the paper and was put out of action. Such as it is, the seismogram shows that the epicentre was about 1400 km. from Zi-ka-wei, and that the time at the origin was 12h. 6m. 5s. (G.M.T.).

The area most strongly shaken lies in the provinces of Kansu and Shensi, in the north-west of the country, in which are situated the origins of the most disastrous of Chinese earthquakes. From the somewhat scanty materials at his disposal, Father Gherzi has constructed the probable courses of the isoseismal lines, using the Mercalli scale. The curves of chief interest are those of degrees 10 and 1. The former surrounds all the places at which the destruction of buildings was total or nearly so. It includes the towns of Pingliang, Kingchow, Kuyuan, and Tsingningchow, and covers a district about 180 miles long, 60 miles wide, and more than 8000 square miles in area. Its longer axis is directed N.N.W. and S.S.E., and is roughly parallel to the axes of the great crust-folds of this region. Assuming this isoseismal to be drawn correctly, it follows that the position of the epicentre is about 35·8° N., 106·2° E.

As in all earthquakes of the first magnitude, the duration of the shock was considerable—according to one observer, who measured it, certainly three minutes. Throughout all this time the shock seemed to vary but little in intensity, though becoming slightly stronger near the middle. The effects of the shock were aggravated by the structure of the country—the rock in the central area being capped by a thick bed of loess, through which the streams have worn ravines with nearly vertical sides. Roads are said to be cut up

by fissures in which houses have disappeared, and are blocked by avalanches which have fallen from the ravines. Father Gherzi estimates the loss of life at more than 40,000, by no means a large figure for an earthquake of this character. Probably the real number will never be known, as it is a custom in this district for families to live in caves hollowed out in the loess along the river-sides, which in many cases were blocked by the fall of avalanches.

The isoseismal 4, which forms the boundary of the known disturbed area, is incomplete towards the west. Its mean radius, in the portion drawn, is about a thousand miles. Thus the disturbed area probably contains more than three million square miles, and is perhaps not much inferior in extent to the whole of Europe. At the present time the largest disturbed areas known to us are those of the Assam earthquake of 1897 (about $1\frac{3}{4}$ million square miles), the Kangra earthquake of 1905 (nearly 2 million square miles), and the Charleston earthquake of 1886 (about 2,800,000 square miles). The last area is, however, bounded by an isoseismal line of intensity 2. If the corresponding isoseismal could have been drawn for the Chinese earthquake, the figure given above for its disturbed area would have to be multiplied several times. In any case it is clear that we are dealing with a shock which, if not the greatest, is certainly one of the greatest, known to us since earthquakes began to be studied.

Since the foregoing was written, a report by a small party of foreign travellers has appeared in the *Times* of June 4. Though the travellers were unable to examine the whole of the central region, they state that the shock was felt principally within an area of 15,000 square miles, bounded approximately by the parallels of 35° and 37° and the meridians of 105° and 107°, thus agreeing with the result deduced from Father Gherzi's map. The loss of life, however, is estimated at a far higher figure than that given above. "The prefectural Taoyin of Pingliang puts the total loss of life at 180,000, or one-third of the whole population; 30,000 perished at Kuyuan. Haicheng appears to have been almost completely buried by the surrounding hills tumbling in upon it, about 70,000 people being entombed." Such a total has but rarely been approached, and only twice, I believe, surpassed. The number of deaths due to the Messina earthquake of 1908 cannot fall far short of 100,000. In the Indian earthquake of 893 180,000 persons are said to have perished; in the Japanese earthquake of 1703, 200,000; and in the Indian earthquake of 1737 the reported number rises to a maximum of 300,000.

Stereochemistry.

AT the seventh Indian Science Congress Prof. B. K. Singh, who presided over the chemistry section, delivered an address on "Recent Advances in Stereochemistry," which has since been published in pamphlet form.

After reviewing the early development of the subject by Pasteur, the theory of the asymmetric carbon of van't Hoff and Le Bel, and the later researches on asymmetric nitrogen, sulphur, and selenium by Pope, Peachey, and others, Prof. Singh proceeds to discuss the more obscure relations subsisting between the amount of rotation and the constitution of the active substances. In this connection he touched on the work of Pickard and Kenyon, the main outcome of whose researches was to indicate a sudden rise of rotation produced at the end of a chain of five or a multiple of five carbon atoms—a phenomenon which was explained by the proximity of the first and fifth carbon atoms in the chain. Reference was also made to the work of H. O. Jones on the activity of quaternary ammonium bases containing different radicals and certain generalisations which followed. The influence of conjugation, as illustrated by the work of Rupe, and the abnormally high rotations produced in the derivatives of amino-camphor were also reviewed. This was followed by a reference to the relation of optical activity to position isomerism, with a discussion of Frankland's theory.

Prof. Singh, who has himself contributed certain observations on the subject, comes to the conclusion that neither Frankland's theory nor what he terms "Cohen's rule" accords with the facts; but omits to point out that both his own and Frankland's observations are made with dissolved substances in which the solvent may, and frequently does, modify the rotation, whereas Cohen and his co-workers purposely avoided the use of any solvent. Finally, the address dealt with those mysterious changes of rotation known as "the Walden inversion," which are effected by certain reagents, when one constituent of an asymmetric group undergoes replacement. The earlier theories based upon change of structure due to the reagent have since been shown to be untenable in the light of the work of Senter and Drew, who find that with the same reagent different solvents may produce a similar inversion. J. B. C.

University and Educational Intelligence.

BIRMINGHAM.—At the meeting of the Council of the University held on Wednesday, June 1, Mr. Walter H. Moberly was appointed to the chair of philosophy to succeed Prof. J. H. Muirhead, who is retiring from the chair in September next. Mr. Moberly is dean, fellow, and tutor of Lincoln College, Oxford, and one of the best known of the younger teachers of political and social philosophy in the Philosophy and History School of that University. His experience of municipal administration as a member of the Oxford City Council and his work with the Workers' Educational Association should contribute to make him a fitting successor to Prof. J. H. Muirhead.

Dr. H. J. W. Tillyard has been appointed to the chair of Russian, and Signorina L. P. di Castelvecchio to the Serena chair of Italian. Dr. Tillyard is the first occupant of the chair of Russian in the University—a chair founded on the fund collected for the purpose by the Birmingham Chamber of Commerce. Signorina di Castelvecchio is the first professor of Italian to occupy the chair founded on a generous benefaction from Mr. Arthur Serena and on funds collected by the Birmingham Chamber of Commerce. She is the first woman to be appointed to a chair in the University.

The Council has also appointed Mr. E. H. F. Mills, fellow of St. John's College, Cambridge, and secretary of the University Library, Cambridge, to the office of librarian which will shortly be vacant by the retirement of Mr. W. H. Cope.

CAMBRIDGE.—Dr. G. E. Moore, Trinity College, and Mr. W. E. Johnson, King's College, have been re-elected University lecturers in moral science, and Mr. F. Debenham, Gonville and Caius College, has been re-elected University lecturer in surveying and cartography. Mr. J. A. Venn, Trinity College, has been nominated Gilbey lecturer in the history and economics of agriculture. Mr. J. C. Wallace has been elected a junior fellow of Emmanuel College.

Miss F. E. Haines has been elected to a scientific fellowship at Girton College, and Miss M. T. Budden to an associates' fellowship in mathematics at Newnham College.

It is proposed to appoint a committee of nine to manage the low-temperature station for research in biochemistry and biophysics, which is nearing completion. Five members of the committee are to be nominated by the council of the Senate and four by the Department of Scientific and Industrial Research.

The Syndicate to consider possible alterations affecting the Mathematical and Natural Sciences Tripos is to consist of Dr. Fitzpatrick, Sir Joseph Thomson, Prof. H. F. Baker, Sir Ernest Rutherford, and Messrs. W. B. Hardy, A. Hutchinson, W. H. Mills, J. Barcroft, J. F. Cameron, A. Wood, C. G. Darwin, R. H. Fowler, and G. P. Thomson.

Dr. H. Hartridge, King's College, has been appointed senior demonstrator in physiology.

Owing to the continued difficulties of railway travelling, the vote on the admission of women to membership of the University or to titular degrees has been postponed from June 16 to October 20.

The Arnold Gerstenberg studentship will be awarded to the science student of proper standing who writes the best essay on one of the following six subjects:—The Ultimate Data of Physics, Philosophical Aspects of the Theory of Relativity, Mechanical Explanation and the Problems of Biology, The Theory of an "Elan Vital" and Related Conceptions, Heredity and Memory, Instinct and Intelligence.

MANCHESTER.—Dr. Harold Robinson, senior lecturer in physics and assistant director of the physical laboratories, has resigned his appointment as from September 29 next.

The following have been recommended for the degree of Doctor of Science:—Frederick William Atack, William Broadhurst Brierley, Colin Campbell, Robert George Fargher, William Harold Pearsall, and Henry Smith Holden.

IN connection with the department of coal gas and fuel industries of Leeds University a Corbet-Woodall scholarship in gas engineering is being offered. It is of the annual value of 60*l*., and tenable for three years, with the possible extension to a fourth. Full particulars can be obtained from the registrar of the University. The latest date for receiving applications for the scholarship is June 15.

SUMMER schools for practical work in open-air geography, geology, botany, and allied sciences will be held under the auspices of the Geographical Association at Chamonix (July 28–August 11) and in Snowdonia (August 13–27). The original glacial researches of De Saussure, Forbes, and Tyndall will be retraced in the Chamonix district, and, similarly, Ramsay's work on the ancient glaciers of North Wales will be studied in Snowdonia. Particulars of the arrangements may be obtained by sending a stamped addressed envelope to Mr. H. Valentine Davis, "Noddfa," Wistaston, Crewe.

THE Bulletin of the National Research Council for March (vol. ii., part 1, No. 9) contains a classified statement compiled by the Research Information Service of the funds available in 1920 in the United States for the encouragement of scientific research. The publication falls into seven sections, of which the first is introductory, and sections ii. to vi. contain lists of the medals, prizes, fellowships, etc., in connection with which specific mention is made of research. In section ii. the various medals and prizes are brought together; section iii. deals with grants for research; section iv. with institution funds for research; and section v. with the fellowships and scholarships available for research workers. In every case reference is made to the awarding body, the nature of the research for which the award is made, the frequency of award, and usually the monetary value. Section vi. consists of an index to the subjects in which funds for research are available; while section vii. forms an index to the various institutions which make awards and to the funds from which grants for research are allotted. A truly remarkable amount of information from widely scattered sources is thus brought together conveniently in a single publication.

THE programme of the Summer School of Civics, to be held this year at Guildford, Surrey, from July 30 to August 13, offers opportunities for good all-round social study. The courses of lectures to be given fall into three groups. In the first come those on geography, descriptive economics, primitive and present-day institutions, and anthropology; through these the student will be given a condensed view of community life at the present day. In the second group are the courses which develop a theory of community life, *e.g.* those on social biology, psychology, philosophy, etc. In the third group come the courses on the principles and practice of civics, social education, public administration, and economic problems. A special course for teachers on modern developments in education will also be given. Informal discussions will be, as formerly, a great feature of the school's work, and there will be exhibitions of civics, rustic surveys, housing and town-planning schemes, and excursions in Guildford and the neighbourhood. Mr. A. Farquharson will be responsible for the general direction of the school, and a number of well-known lecturers have offered their services. The inaugural lecture will be given by Prof. Patrick Geddes, professor of sociology and civics in the University of Bombay, and special lectures on psycho-analysis are being given by Miss Barbara Low. Full particulars of the school may be obtained from Miss Margaret Tatton, secretary, Civic Education League, Leplay House, 65 Belgrave Road, Westminster, S.W.1.

ONE of the prime features of the Education Act of 1918 was that establishing day continuation schools for young persons entering upon employment at fourteen years of age. Immediate provision was to be made by the various local education authorities for education during working hours for such young persons for seven or eight hours weekly for forty weeks of each of two following years. Many large firms in the North of England, chiefly textile and engineering, took advantage of the provision so made and established for their own employees classes of a liberal character during working hours. Some education authorities, of which Manchester is a notable example, also established facilities for continued day education. The London County Council was one of the very few authorities which adopted the Act, and the Board of Education thereupon named an appointed day in the terms of the Act. The Education Committee of the L.C.C., among its other activities, made large provision for the means of continued day education, which received a gratifying response. It is therefore a matter of much surprise that the Education Committee of the Council resolved on May 9, and confirmed at a meeting held on June 1, that the Council's interim scheme adopted on May 4 of last year be amended so as to provide for the continued day education of employed young persons up to 15 years of age only. The reason given for this decision is that the cost of continued education for two years under the Act is too great in face of the growing unwillingness of the people to pay increased rates. Apart from the serious injury to the young persons concerned, it is a proposal of very doubtful legality, and it is to be hoped that the recommendation to the Council, which was carried by a majority of only one, will be summarily rejected.

Calendar of Scientific Pioneers.

June 9, 1875. Gérard Paul Deshayes died.—A founder of the Geological Society of France, Deshayes was distinguished for his study of the fossil mollusca of the Paris basin. He assisted Lyell in the classification of the Tertiary system into Eocene, Miocene, and Pliocene.

June 10, 1836. André Marie Ampère died.—A teacher first at Bourg and Lyons, Ampère in 1805 became a professor at the Ecole Polytechnique, and in 1824 was appointed to the chair of experimental physics in the Collège de France. Like Oersted, Faraday, and Henry, he was a pioneer in the science of electrodynamics, which he developed with mathematical skill. His "Observations Electro-dynamiques" appeared in 1822 and his "Théorie des Phénomènes Electro-dynamiques" in 1830.

June 10, 1858. Robert Brown died.—Beginning life as an assistant surgeon in a Scottish regiment, through Banks Brown in 1801 went to Australia with Flinders in the *Investigator,* and four years later returned with a collection of 4000 plants. He was afterwards placed in charge of Banks's collections and became botanical keeper at the British Museum. The foremost botanist of his day, his works embrace not only systematic botany, but also plant anatomy and physiology. Humboldt called him "facile princeps botanicorum."

June 10, 1903. Luigi Cremona died.—Distinguished for his work in synthetic geometry, Cremona for thirty years was professor of higher mathematics in the University of Rome. He reorganised the mathematical instruction in Italy, and for a time was Minister of Education.

June 11, 1875. Joseph Winlock died.—For some years superintendent of the American "Nautical Almanac," Winlock in 1865 succeeded G. P. Bond as professor of astronomy and director of the observatory at Harvard.

June 11, 1897. Karl Remegius Fresenius died.—A student at Bonn and then assistant to Liebig, Fresenius from 1845 onwards was professor of chemistry and technology at the Agricultural Institute at Wiesbaden. He made many analytical researches, wrote standard text-books, and in 1862 founded the *Zeitschrift für analytische Chemie.*

June 12, 1885. Henry Charles Fleeming Jenkin died.—The assistant of Lord Kelvin in his important experiments on the resistance and insulation and the making of electric cables, Jenkin afterwards occupied the chairs of engineering in University College, London (1865), and in Edinburgh University (1868).

June 13, 1844. Thomas Charles Hope died.—Hope in 1799 succeeded Black as professor of chemistry in Edinburgh University. Unrivalled as a popular teacher, more than 16,000 students attended his lectures. To him we owe the demonstration that water attains its maximum density at 4° C.

June 14, 1746. Colin Maclaurin died.—Born in 1698, Maclaurin at the age of nineteen became professor of mathematics at Aberdeen. In 1725 he was appointed to the similar chair at Edinburgh. After Newton's death he was recognised as the foremost British mathematician. He died at York, his death being due to his exertions during the Rebellion of '45.

June 14, 1875. Heinrich Louis D'Arrest died.—Of Huguenot descent, D'Arrest was born and educated at Berlin. He assisted Encke, held the chair of mathematics and astronomy at Leipzig, and in 1857 became director of Copenhagen Observatory.

June 14, 1903. Karl Gegenbaur died.—Famous for his work in comparative anatomy, Gegenbaur held the chairs of anatomy at Jena and Heidelberg. His "Elements of Comparative Anatomy" appeared in 1874.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, June 2.—Prof. C. S. Sherrington, president, in the chair.—Bakerian lecture by Dr. T. M. **Lowry** and Dr. C. P. **Austin**: Optical rotatory dispersion. Although no case is known in which Biot's law of inverse squares, $\alpha=k/\lambda^2$, is accurately true, the rotatory dispersion in a very large number of organic compounds can be expressed by the *simple dispersion formula,* $\alpha=k/(\lambda^2-\lambda_0^2)$, which differs from Biot's formula only in the introduction of a "dispersion constant" λ_0^2. This formula is a special case of the general formula $\alpha=\Sigma k_n/(\lambda^2-\lambda_n^2)$ introduced by Drude as an approximation based upon the electronic theory of radiation and absorption of light. Substances which require more than one term of this equation are said to show *complex rotatory dispersion.* Tartaric acid and its esters give dispersion curves which frequently show an inflexion, a maximum, and a change of sign; they are described as cases of *anomalous rotatory dispersion.* These can be represented by two terms of Drude's equation, while the rotatory dispersion in quartz was represented by a similar equation, in which the dispersion-constant of the negative term was negligible. In order to express recent measurements it is necessary to assume finite values for both dispersion-constants and to introduce a term to express the influence of the infra-red absorptions; this can be taken as a constant. The anomalous dispersion of tartaric acid was attributed by Arndtsen in 1858 to the presence of two modifications of the acid differing in the sign of their rotations and in the magnitude of their dispersions. This view has been confirmed (1) by the proof that the complex rotatory dispersion of the acid and its derivatives can be expressed as the sum of two simple dispersions, and (2) by the discovery of certain "fixed" derivatives of tartaric acid which exhibit simple rotatory dispersion. Attention is directed to some analogies between tartaric acid and nitrocamphor, which give two isomeric compounds in solution.

Zoological Society, May 24.—Prof. E. W. MacBride, vice-president, in the chair.—Dr. C. W. **Andrews**: The skull of *Dinotherium giganteum* in the British Museum.—Dr. C. F. **Sonntag**: (1) The comparative anatomy of the tongues of the Mammalia, Families 3 and 4, Cebidæ and Hapalidæ. (2) Some points in the anatomy of the tongues of the Lemuroidea.—Prof. R. **Broom**: Some new genera and species of anomodont reptiles from the Karroo beds of South Africa.—R. I. **Pocock**: The external characters of some species of Lutrinæ (otters).

Geological Society, May 25.—Mr. R. D. Oldham, president, in the chair.—G. W. **Lamplugh**: The junction of Gault and Lower Greensand near Leighton Buzzard (Bedfordshire). The paper, a continuation of one by the author and the late J. F. Walker published in 1903, describes about twenty sections exhibiting the base of the Gault in excavations around Leighton Buzzard. The variable "Basement Beds" of the Gault are "condensed" deposits, falling mainly within the "zone of Ammonites mammillatus" as recognised in northern France. The evidence bears out Jukes-Browne's suggestion of the occurrence of a current-swept strait in this quarter during late Lower Cretaceous times. During the accumulation of the "Basement Beds" a shoal in this strait north of Leighton formed a reef, while the deeper water to the southward gathered a stratum of gritty glauconitic loam and clay with fossiliferous phosphatic nodules. The transitional stages are visible in the sections. The dark clays above the "Basement Beds" belong to the Lower Gault, here reduced to about half its thickness at Folkestone. They rest sharply on the

ironstone "pans" of the reef, but usually pass downward by gritty intercalations into the glauconitic loams. The incoming of the Upper Gault, with keeled ammonites, is shown in three of the sections. A band of corroded phosphatic nodules, like those of the "Junction-Bed" at Folkestone, occurs near the base of the division, and marks a long pause in the sedimentation. This band has yielded many fossils. The palæontology of the deposits is discussed, and is held to be in general agreement with that of the same succession in northern France.

Physical Society, May 27.—Sir W. H. Bragg, president, in the chair.—H. **Pealing**: The reflection of the X-ray spectrum of palladium from fluorspar. An examination of the odd order spectra reflected from the 100 plane of fluorspar, using palladium X-rays, has been made with the view of testing the Lewis-Langmuir theory of the motion of valency electrons in compounds. Evidence in partial confirmation of the theory has been obtained.—Sir W. H. **Bragg**: The intensity of X-ray reflection by diamond. The relative intensities of the reflections of monochromatic X-rays by the crystallographic planes of diamond are given. The special difficulties due to the small size of available crystals are discussed. The results lie very closely on smooth curves, indicating that if the outer electrons of the carbon atom lie at any considerable distance from the centre they must be in motion over a wide range, or for some other reason must contribute little to the reflection. The properties of the carbon atom in diamond are based on a tetrahedral form. The tetrahedra point away from any (111) plane in the case of half the atoms, and towards it in the case of the other half. Consecutive 111 planes are not exactly of the same nature, and consequently some slight second-order reflection from the tetrahedral plane might be expected. This effect, though slight, has been found.—Research Staff of the **General Electric Co., Ltd.**: A method for the micro-analysis of gases by the use of the Pirani pressure gauge. A method of analysis of gases at a pressure between 0·61 and 0·001 mm. is described, based on the characteristic vapour-pressure temperature curve of any substance. A gauge such as the Pirani gauge, which will measure the pressures of vapours, as well as of permanent gases, over the range mentioned is used.

MANCHESTER.

Literary and Philosophical Society, February 8.—Sir Henry A. Miers, president, in the chair.—C. W. **Duckworth**: Note on a unique set of hydrometers.—Prof. G. **Unwin**: Samuel Oldknow, the first manufacturer of British muslins. An account of Oldknow's records (1782–1812), including the whole process of manufacture.

Literary and Philosophical Society and the Faraday Society (Joint Meeting), February 11.—Prof. A. W. Porter, president of the Faraday Society, in the chair.—Dr. A. **Ferguson**: Studies in capillarity. Part i.: Some general considerations, and a discussion of the methods of measuring interfacial tensions. The importance of accurate measurements of surface tensions, in view of the development of colloid physics, is becoming increasingly manifest, and a systematic determination of capillary constants is urgently needed. In this paper the "genetic" relations of various methods for the measurement of surface tensions are discussed. A critical comparison of these shows that among the most promising methods for systematic use are those depending on the measurement of (1) large bubbles or drops, (2) the maximum pressure required to release a bubble of air from the end of a capillary tube immersed in the liquid, and (3) the maximum pull on an anchor ring which is immersed in the liquid and slowly withdrawn. Dealing with the ascent of a liquid in a capillary tube, it is shown that where a^2 is the specific cohesion and h the height to which the liquid rises in a tube of radius r, the equation

$$2a^2 = rh(1 + rh/3 - 0{\cdot}1288\, r^2/h^2)$$

is adequate for all requirements. Methods are proposed for the measurement of the surface tensions of such liquids as molten metals, and the problem of the accurate measurement of interfacial tensions is discussed.—Dr. A. **Ferguson** and P. E. **Dowson**: Studies in capillarity. Part ii.: A modification of the capillary tube method for the measurement of surface tensions. A modification of the usual method is proposed in which the meniscus is forced down to the end of the capillary immersed vertically in the liquid, and the pressure required to effect this is measured on a separate manometer. Apart from small corrections, the difference in level of the surfaces of the liquid in the gauge is equal to the heights to which the same liquid would rise in the capillary tube employed. By using a specially light liquid in the gauge this difference may therefore be magnified. But any manometer of sufficient delicacy may be used and the use of a cathetometer avoided. Thus the differential manometer or a simple sloping-tube manometer will give accurate results by ordinary naked-eye estimations. Temperature control becomes relatively simple, and the temperature of the meniscus may be estimated by means of a thermo-junction placed close to the end of the tube. Calibration of the capillary is unnecessary, for measurements are always made with the meniscus in one definite position—at the end of the tube.

DUBLIN.

Royal Dublin Society, May 24.—Dr. F. E. Hackett in the chair.—Prof. T. **Johnson** and Miss J. G. **Gilmore**: The occurrence of Dewalquea in the core of the bore made at Washing Bay, Co. Tyrone. This bore, made to tap a concealed coalfield if possible, had to be abandoned owing to the unexpected thickness of the bed of Lough Neagh Clay encountered (1196 ft. instead of 250 ft.), and from other causes. Plant-remains were obtained, especially at a depth of 870–930 ft., above the lithomarge or basalt. The hellebore-like foliage of Dewalquea was found represented by three new species, *D. hibernica*, *D. fraxinifolia*, and *D. denticulata*, of which particulars are given. The authors restored the leaves and found peltate scales, like those of Engelhardtia, present. They regard Dewalquea as an ancient member of the Juglandaceæ. It is recorded from the Cretaceous of America and Europe, also from Belgium (Lower Eocene) and Italy (Oligocene). The plant-beds at Washing Bay are probably Upper Oligocene.—The late Prof. J. A. **McClelland** and J. J. **McHenry**: Uncharged nuclei produced in moist air by ultra-violet light and other sources. The uncharged nuclei produced in moist air by ultra-violet light were given an electric charge through the agency of uranium. Their number and size could then be readily found under varying conditions. It is concluded that they are minute drops of water, and that they probably owe their formation to the production of hydrogen peroxide. The nuclei produced by heating glass were also studied. Moderate heating caused a temporary evolution of nuclei, attributed to surface impurities absorbed from the atmosphere. Strong heating caused a continuous evolution, attributed to disintegration of the glass. Similar effects were observed with metals.—H. G. **Becker**: A simple apparatus for observing the rate of reaction between gases and liquids, and the determination thereby of

the effect of stirring on the rate of solution of oxygen in water. The principle is similar to that already described elsewhere by Dr. Adeney, and consists in enclosing the liquid with a known volume of gas in a space connected to a manometer and observing the change of pressure due to absorption. Experiments made on the effect of stirring on the rate of absorption of oxygen from the air showed that the rate of solution is enormously increased even by gentle stirring of the liquid, and with more vigorous stirring tends to the maximum value already found by a different method. The experiments form a link between conditions occurring in Nature and those obtaining in the method previously described by Adeney and Becker in the society's Proceedings.

PARIS.

Academy of Sciences, May 17.—M. Georges Lemoine in the chair.—A. **Denjoy**: The calculation of the coefficients of any convergent trigonometrical series the sum of which is given.—G. **Dumas**: The framing contours.—M. **Bratu**: Series the general term of which tends towards zero.—G. **Valiron**: Integral functions of finite order.—J. **Le Roux**: The theory of relativity and the secular movement of the perihelion of Mercury.—B. **Lyot**: The aurora borealis of May 14–15, 1921, and the simultaneous magnetic phenomena. Intense magnetic disturbances commenced twenty hours before the passage of an important group of sun-spots across the central meridian, and this passage was followed by a remarkable aurora borealis.—J. **Guillaume**: Observation of Pons-Winnecke's comet (1921*b*) made with the equatorial of the Observatory of Lyons. Position on May 10 is given. The comet is roughly circular, with a faint central condensation. Magnitude about 11·5.—G. **Vavon** and J. **Detrie**: The transformation of phenol into *cyclo*hexanol. A study of the addition of hydrogen to phenol, with platinum as the catalyst. It is shown that *cyclo*hexanone is formed as an intermediate product.—T. **Martinet** and P. **Coisset**: The action of chloraloxim on the aromatic amines; the synthesis of isatins. When the oxime of chloral condenses with aromatic amines the chlorine, and not the aldehydic oxygen, reacts. The product of the condensation treated with hot sulphuric acid yields isatin. Starting with various substituted amines, the corresponding substituted isatins can be readily prepared. —M. **Lespieau**: The action of 2:3-dibromopropylene upon *iso*propylmagnesium bromide.—MM. **Delépine**, **Fleury**, and **Ville**: Researches on $\beta\beta$-dichloroethyl sulphide. The material prepared from ethylene and chlorides of sulphur contains various impurities. These give some sulphur as sulphuric acid on oxidation, and only from 60 to 70 per cent. of the chlorine is removed by hydrolysis with water at 80° C. The pure material gives no sulphuric acid on oxidation, and the whole of the chlorine is removed by hydrolysis.—R. **Fosse** and G. **Laude**: Syntheses of cyanic acid and of urea by the oxidation of ketones, acids, and amines in the presence of ammonia.—G. **Arambourg**: The ichthyological fauna of the Sahelian of the Oran region.—A. **Magnan**: The ratio of the wing surface to the caudal surface in birds.—F. **Ladreyt**: Histological and histochemical researches on the pigmentary atrophy of the liver.—A. **Weber**: Researches on the toxicity of the internal medium of Batrachians towards their eggs.—V. **Galippe** and Mme. G. **Soufland**: Researches on the presence in meteorites, hard stones, minerals, quartz, granite, basalt, volcanic ashes, and lava of "organites" susceptible of reviving, and on their resistance to high temperatures.—E. **Chatton** and R. **Courrier**: A trypanosome of the bat, *Vesperugo pipistrellus.* Hypothesis relative to the etiology of endemic goitre. In Lower Alsace about 10 per cent. of these bats are infected with a trypanosome resembling *Schistotrypanum Cruzi*, but smaller. The suggestion is made that this organism may possibly be the cause of endemic goitre.—A. **Sartory** and P. **Bailly**: The agglutinating power of thorium sulphate on the spores of *Aspergillus fumigatus.* An emulsion of the spores was clarified by solutions of thorium sulphate, the maximum effect being produced at concentrations between 0·001 and 0·0005. Concentrated solutions do not agglutinate the spores.—G. **Marinesco** and E. **Craciun**: Lesions of the nervous system in exanthematic typhus and their relations with neuritis.—C. **Lebailly**: The preservation of the aphthous virus by cold.

ROME.

Reale Accademia nazionale dei Lincei, March 6.—V. Volterra, vice-president, in the chair.—Paper by a fellow:—Col. G. A. **Crocco**: Utilisable energy of the wind. The variability of winds, coupled with the fact that the energy varies as the cube of the velocity, has hitherto prevented this source of energy from being put to much practical use. Referring to accumulators, the author considers that recent researches on thermal accumulators offer an opportunity for storing this energy in a form adapted for heating purposes at a moderate cost. Regarding the installation of generators, the author suggests the construction of barrages fixed in such localities as a gap between mountains, where the prevailing wind is more or less constant in direction. It is also pointed out that after passing an obstacle the wind soon almost recovers its original velocity, so that by fixing several installations one behind the other it is possible to utilise the energy contained in a considerable height of air.—Papers communicated through fellows:—M. **Picone**: Potential of a double surface layer. This extract from a letter to Prof. Levi Civita deals with a proof that the potential of a magnetic shell has finite, definite value of the surface of the shell except at a singular point.—Prof. A. **Lo Surdo**: A spectroscope with catoptric grating. This arrangement consists of a number of reflecting laminæ of equal thickness overlapping each other by the same amount, their edges thus resembling a flight of steps, by reflection from which a diffraction spectrum is formed of a beam of light incident normally to the laminæ.—Prof. G. **Magrini**: Preliminary notice of the Italian expedition for exploring the seas of the Levant. This expedition formed the part assigned to Italy in carrying out the programme arranged in 1919 under the auspices of the International Commission for the Scientific Exploration of the Mediterranean. For this purpose the *Tremiti*, of 500 tons, was equipped, the fundamental problem to be investigated being the distribution and cause of the currents in the Bosphorus and the Dardanelles.—Dr. C. **Perrier**: The true nature of Rosasite, ii.—G. **Stefanini**: Geology of Cyrenaica: i., Eocene strata. An examination of literature and materials, considered especially in relation to the previous researches of Prof. J. W. Gregory (Quart. Journ. Geol. Soc., vol. lxvii., 1911).—A notice of the life and work of the late Prof. P. A. Saccardo, read on February 6 by Prof. O. Mattirolo, occupies twelve pages at the end of the number of the Atti containing the previous papers.

March 20.—F. D'Ovidio, president, in the chair.—Papers by fellows:—F. **Severi**: Theory of simple integrals of the first species belonging to an algebraic surface, i.—C. **De Stefani**: Ligurian fossil sponges, v. Mulino di San Giovanni, Biscazza, Casa Buzzano,

Caffarella.—G. **Pellizzari**: Transition from guanidine to cyanoamide, and from diguanide to dicyanodiamide.—Papers communicated through fellows:—C. **Burali-Forti**: Real numbers and magnitudes, i.—A. **Artom**: Apparatus for directional radio-mechanics. The currents from two receivers at right angles (or at any other angle) operate on two separate galvanometer coils, fixed at a similar angle to the receivers, in such a way that the deviation of the galvanometer needle depends on the difference of intensity of the currents generated in the coils, and its position thus indicates the direction from which the radio-telegraphic waves are received. The apparatus admits of several modifications.—The present number of the Atti contains obituary notices read at the preceding meeting (March 6) by Prof. R. Pirotta on the late Prof. G. Cuboni, and by Prof. Cerulli on the late Prof. Giovanni Celoria.

NEW SOUTH WALES.

Linnean Society, March 30.—Mr. J. J. Fletcher, president, in the chair.—J. J. **Fletcher**: Presidential address. The work of the society during the past year was reviewed and reference made to recent important events of scientific interest, including the establishment of the Australian National Research Council and of the Commonwealth Institute of Science and Industry; the first Pan-Pacific Science Conference; and the resumption of regular meetings of the Australasian Association for the Advancement of Science. The last part of the address referred to the Macleay Museum of the Sydney University, founded by Sir William Macleay. The history of the formation of the Macleay collections was related. In conclusion, the University of Sydney, which is joint trustee with the society for the museum, was criticised for neglect of its trust. Changes made in the building have caused the disruption of the Macleay collections, so that they no longer form an exposition of the fauna of Australia.—Mr. G. A. Waterhouse, elected president for the year 1921–22, then took the chair.—E. W. **Ferguson**: Revision of the Amycterides (Coleoptera). Part vi., Acantholophus. A detailed historical account is given, together with a critical revision of the genus and of the species referred to it. The genus is divided into two sections; in the first, the head is separated from the rostrum by the intercristal ridge, the prothorax is produced above, and ocular lobes are present; in the second the head is separated from the rostrum by a transverse impression, the prothorax is subtruncate above, and ocular lobes are absent. Fifty-nine species, ten of them new, are referred to the genus.—Dr. R. **Greig-Smith**: The high-temperature organism of fermenting tan bark. Part i. The fermentation of spent wattle-bark in the corrosion of white lead is caused by a stout, rod-shaped bacterium having a terminal spore. Its optimum laboratory temperature is 60° C.; in the corroding stacks the temperature may rise to 80°. Raw spent wattle-bark requires preliminary treatment. As conditions which oxidise tannin substances favour the fermentation of the raw bark, it is probable that the residual tannins inhibit fermentation.

Books Received.

Introduction to the Theory of Fourier's Series and Integrals and the Mathematical Theory of the Conduction of Heat. By Prof. H. S. Carslaw. Second edition, completely revised. Vol. i.: Fourier's Series and Integrals. Pp. xi+323. (London: Macmillan and Co., Ltd.) 30*s*. net.

The Fine Cotton Spinners' and Doublers' Association, Ltd., Manchester: Experimental Department. A Method for Measuring the Length of Cotton Hairs. By Dr. W. Lawrence Balls. Pp. 62. (London: Macmillan and Co., Ltd.) 3*s*. 6*d*. net.

The Purple Sapphire and other Posthumous Papers. Selected from the Unofficial Records of the University of Cosmopoli by Christopher Blayre. Pp. x+210. (London: P. Allan and Co.) 7*s*. 6*d*. net.

The Scientific Papers of the Hon. Henry Cavendish, F.R.S. Vol. i.: The Electrical Researches. Edited by Prof. J. Clerk Maxwell, revised by Sir Joseph Larmor. Pp. xxviii+452. Vol. ii.: Chemical and Dynamical. Edited by Sir Edward Thorpe. Pp. xii+496+vi plates. (Cambridge: At the University Press.) 6*l*. net the 2 vols.

The Salvaging of Civilization. By H. G. Wells. Pp. v+202. (London: Cassell and Co., Ltd.) 7*s*. 6*d*. net.

Festschrift der Kaiser Wilhelm Gesellschaft zur Förderung der Wissenschaften zu ihrem Zehnjährigen Jubiläum Dargebracht von ihren Instituten. Pp. iv+282. (Berlin: J. Springer.) 100 marks.

The Psychology of Day-Dreams. By Dr. J. Varendonck. Pp. 367. (London: G. Allen and Unwin, Ltd.; New York: The Macmillan Co.) 18*s*. net.

The Case-Hardening of Steel. By Harry Brearley. Second edition. Pp. xi+207. (London: Longmans, Green and Co.) 16*s*. net.

Factory Chemistry: Preparatory to Courses in Metallurgy and Metallography. By Wm. H. Hawkes. Pp. vii+59. (London: Longmans, Green and Co.) 4*s*. 6*d*. net.

The Correspondence of Commerce. By A. Risdon Palmer. (Pitman's Commerce Series.) Pp. xii+159. (London: Sir I. Pitman and Sons, Ltd.) 6*s*. net.

Ameboid Movement. By Prof. Asa A. Schaeffer. Pp. vii+156. (Princeton: University Press; London: Oxford University Press.) 10*s*. 6*d*. net.

La forme et le Mouvement. Essai de Dynamique de la Vie. By Georges Bohn. Pp. 175. (Paris: E. Flammarion.) 4.50 francs net.

Petrographic Methods and Calculations, with some Examples of Results Achieved. By Dr. Arthur Holmes. Pp. xix+515+iv plates. (London: T. Murby and Co.) 31*s*. 6*d*. net.

Diary of Societies.

THURSDAY, JUNE 9.

INSTITUTION OF MINING ENGINEERS (at Geological Society), at 11.—Third Report of the Committee on "The Control of Atmospheric Conditions in Hot and Deep Mines."—J. P. Rees: Observations of Temperature and Moisture in Deep Coal-mines.—Prof. H. Briggs: Characteristics of Outbursts of Gas in Mines.—H. C. Harrison: The Use and Distribution of Shale-dust in Mines. The following papers, which have already appeared in the Transactions, will be discussed:—A. E. Beet and A. E. Findley: The Better Utilisation of Coking Slack.—J. I. Graham: The Normal Occurrence of Carbon Monoxide in Coal-mines.—T. L. Galloway: An Improved Method of Determining the Relative Directions of Two Reference-lines or Bases for Mining Surveys.—E. Bury, W. Broadbridge, and A. Hutchinson: Froth Flotation as Applied to the Washing of Industrial Coal.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital), at 4.30.—Dr. H. Head: Release of Function in the Nervous System.

ROYAL SOCIETY, at 4.30.—Prof. C. S. Sherrington: Break-shock Reflexes and "Supramaximal" Contraction-response of Mammalian Nerve-muscle to Single-shock Stimuli.—R. J. Ludford and J. B. Gatenby: Dictyokinesis in Germ Cells, or the Distribution of the Golgi Apparatus during Cell Division.—Dr. F. W. Edridge-Green: The Effect of Red Fatigue on the White Equation.—E. Ponder: A Method for Investigating the Hæmolytic Activity of Chemical Substances.—W. H. Pearsall: The Development of Vegetation in the English Lakes, considered in Relation to the General Evolution of Glacial Lakes and Rock Basins.

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—M. J. Conran: Curvature and Torsion in Elliptic Space.—J. L. S. Hatton: The Inscribed, Circumscribed, and Self-conjugate Polygons of Two Conics.—M. J. M. Hill: The Differential Equations of the First Order derivable from an Irreducible Algebraic Primitive.—F. S. Macaulay: Note on the Resultant of a Number of Polynomials of the Same Degree.—Lt.-Col. A. Cunningham: The Congruence $2^{p-1} \equiv 0 \pmod{p^2}$.—T. Stuart: Diophantine Equations.—G. H. Hardy: A Chapter from Ramanujan's Note-book.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. F. L. Golla: The Objective Study of Neurosis (Croonian Lecture).

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 5.—H. S. Goodhart-Rendel: Some Fashions in Architecture.

OPTICAL SOCIETY (at Imperial College of Science), at 7.30.—H. Lee: Achromatism.—W. L. Custance: Demonstration of the Société Genevoise Universal Measuring Machine.

PAINT AND VARNISH SOCIETY (at St. Bride's Institute), at 7.30.—C. A. Klein: The Need for Science and Common Sense in the Practical Testing of Paints.

FRIDAY, JUNE 10.

ROYAL SOCIETY OF ARTS (Indian Section), at 4.30.—Sir George Curtis: The Development of Bombay.

ROYAL ASTRONOMICAL SOCIETY, at 5.—Rev. J. G. Hagen: The Origin of Temporary Stars and of Planetary Nebulæ.—S. D. Tscherny: Results of Observations of Sun-spots and Faculæ, 1916-1920, made at the Observatory, Rostow-on-Don.—A. A. Rambaut: Parallaxes of 516 Stars, from Photographs taken at the Radcliffe Observatory, Oxford.—E. A. Milne: Radiative Equilibrium: The Effect of a Strong Absorption Line.—W. M. Smart: Proper Motions of Stars in the Pleiades.—Rev. A. L. Cortie: The Sun-spot Group and the Magnetic Disturbances, 1921 May 8-21.—F. Sargent: Remarkable Spot on the South Equatorial Belt of Jupiter.—Rev. T. E. R. Phillips: Micrometrical Measures of Double Stars.—Royal Observatory, Greenwich: Note on the Measurement of Groups of Sun-spots.—Royal Observatory, Greenwich: Observations of Comets *a* 1921 (Reid); *b* 1921 (Pons-Winnecke); *c* 1921 (Dubiago).

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—Sir Ernest Rutherford: The Stability of Atoms (Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr. A. G. Webster: Absolute Measurements of Sound.

TUESDAY, JUNE 14.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. F. L. Golla: The Objective Study of Neurosis (Croonian Lecture).

WEDNESDAY, JUNE 15.

ROYAL METEOROLOGICAL SOCIETY, at 5.—G. M. B. Dobson: Causes of Errors in Forecasting Pressure Gradients and Wind.—R. F. Granger: The Physical Structure of Cloud-Form in the Lower Atmosphere.—N. A. Comissopulos and J. Wadsworth: Variability of Temperature over North America and Europe during the Ten Years, 1900-1909.

ROYAL MICROSCOPICAL SOCIETY, at 8.—Prof. F. J. Cheshire: A Selection from the Abbe Letters.—Dr. C. F. Sonntag: Some Points in the Histology of the Three-Toed Sloth.—F. Chapman: Ostracoda, Foraminifera, and Some Organisms related to Calcisphæræ, from the Devonian of Germany.—G. T. Harris: Note on Mounting in Glycerine Jelly.

THURSDAY, JUNE 16.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital), at 4.30.—Prof. W. Bulloch: Use and Abuse of Scientific Medical Literature.

ROYAL SOCIETY, at 4.30.—*Probable Papers*.—Prof. H. B. Dixon, Dr. C. Campbell, and Dr. A. Parker: The Velocity of Sound in Gases at High Temperatures, and the Ratio of the Specific Heats.—Prof. J. R. Partington: The Ratio of the Specific Heats of Air and of Carbon Dioxide.—Dr. A. B. Wood and Dr. F. B. Young: "Light Body" Hydrophones and the Directional Properties of Microphones.—Dr. A. B. Wood and Dr. F. B. Young: The Acoustic Disturbances produced by Small Bodies in Plane Waves transmitted through Water, with Special Reference to the Single Plate Direction Finder.—M. A. Giblett: Some Problems connected with Evaporation from Large Expanses of Water.—F. C. Toy: The Photographic Efficiency of Heterogeneous Light.

LINNEAN SOCIETY, at 5.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. F. L. Golla: The Objective Study of Neurosis (Croonian Lecture).

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 8.—Prof. B. Moore: The Natural Photo-synthetic Processes on Land and in Sea and Air, and their Relation to the Origin and Preservation of Life upon the Earth (Hugo Müller Lecture).

RÖNTGEN SOCIETY (at University College), at 8.15.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.15.—Lecture.

ROYAL SOCIETY OF MEDICINE (General Meeting), at 8.30.—Sir Thomas Horder, Dr. A. F. Hurst, Sir Berkeley Moynihan, Sir Humphry Rolleston, and Others: The Problem of the Private Clinic System in Great Britain.

FRIDAY, JUNE 17.

ROYAL ASTRONOMICAL SOCIETY, Geophysical Discussion, at 5.—Changes of Level in the British Isles, opened by H. L. P. Jolly, followed by Col. Sir C. F. Close and O. G. S. Crawford. Chairman: Col. Sir G. Lenox-Conyngham.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—J. C. Warburg: Foregrounds.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (at Kensington Town Hall), at 8.15.—Dr. C. Addison: The Part of the State in the Prevention of Disease (Cavendish Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir J. J. Thomson: Chemical Combination and the Structure of the Molecule.

The Safeguarding of Research.

THE fact that the Bill for the Safeguarding of Industries has passed its second reading in the House of Commons has directed renewed attention to the manner in which its provisions will react on the prosecution of scientific research in this country. It will be remembered that the supply of scientific apparatus and chemicals was the subject of a discussion in our correspondence columns about a year ago, and we have received many further letters showing the importance of the question. In NATURE for June 9, p. 457, attention was directed to the formation of a committee of the British Science Guild to report upon the matter. We hope that all our readers who have knowledge of facts bearing on the problem, or suggestions to offer, will give this committee the benefit of their views.

Our concern here is for the advancement of scientific discovery, which is the only real basis for the safeguarding of all industrial development. For this reason we think that the point of view of the user and consumer, more particularly that of the worker in science, should receive chief attention. Certain documents that have been issued suggest rather that the interest of the manufacturer is to be the primary consideration. Although British men of science are undoubtedly desirous of supporting the industries of their country, even if they have to pay a somewhat higher price for the goods, it is clearly their duty to see to it that the main object of their work does not suffer thereby. Great improvements have been made in British laboratory ware, but there are still difficulties in obtaining a sufficient supply of apparatus and chemicals on which reliance can be placed.

Users would be saved no small waste of time and receive encouragement in their purchase of British goods if they knew how far they could really depend on these being what they profess to be. Prof. Cohen's experience with propyl alcohol, as given in NATURE for March 3, p. 12, is to the point here. It is not meant to imply that even the best German chemicals are beyond reproach, although some workers appear to be under the impression that if they use Kahlbaum's preparations no further control of purity is needed. Excellent glass and porcelain is certainly being made here, and our optical and electrical apparatus is second to none. But the price is often very high, and there are still uncertainties in the uniformity of the supply. There appear to be no difficulties in the manufacture of articles for domestic use, and if manufacturers do not find it worth while to put good workers on to scientific apparatus, which has a comparatively small sale, why do they not give it up? The suggestion has been made that purchasers should return any unstamped glass ware, while payment might be refused for goods the origin of which is not stated.

The problem is to discover how best to enable manufacturers to perfect their processes and to protect them from loss while this is being done. It is superfluous to say that the great need is for more and more research, and any legislation that tends to remove the opportunity for this is to be deprecated. The manufacturers appear to dread the competition of countries of which the currency is depreciated. But it is to be noted that the Bill applies to Allied and neutral countries as well as to Germany. Moreover, as was evident in the discussion in the House of Commons, the opinion of many competent speakers is that such competition is exaggerated, and that in any case a depreciated currency is of no real advantage in the world markets, and will continue until normal trade relations are restored. The bankers' manifesto points out that the only satisfactory way of dealing with the situation is to allow trade complete freedom to develop on its own initiative. Artificial attempts to remedy conditions that can right themselves only by the greatest expansion of trade in all directions delay any real solution. This is very far from saying that nothing is to be done at all. The most effective way of avoiding dumping is surely to aim at raising depreciated money value, rather than to restrict trade by import duties.

So far as makers of scientific apparatus are

concerned, we believe they are not satisfied with import duties, and want prohibition of import for a time, with permits to import in special cases. Many consumers have stated their preference for a system of subsidies to enable prices to be low enough to compete with foreign goods. Such a scheme naturally offers difficulties, and there would need to be assurance that efforts at improvement are being made. There seems to be no reasonable objection to the price being made as nearly as possible equal to that of the foreign article, so that the competition should become one of quality. The Bill, however, will probably be passed, although it may still be possible to insert provisions to enable free import to recognised scientific institutions. Such permits must be of a general character, not requiring renewal, and not demanding the intervention of the Customs or other Government Department. No special licences for individual cases would be satisfactory.

How obstructive to scientific progress the Customs regulations may be is shown by letters that have appeared in these columns. The question of books is a very serious one. Incidentally, reference may be made to the increasing difficulty of publication of scientific papers, which seems to be greater in England than in other countries. But here again what is wanted is a general fall in prices, and this can be brought about only by a return to normal trade relations throughout the world.

Much stress was laid by certain speakers in the House of Commons on the necessity of our industries as a national insurance in case of future war. The only remark that need be made in this place is that the most important matter is to keep abreast of scientific work in other countries. Restriction of research is likely to do more harm than the more or less ineffective artificial protection of a few industries would do good. It is to be hoped, therefore, that institutions in which such scientific research is carried on will be placed beyond the effect of the new restrictions on import.

Steam and Thermodynamic Theory.

Properties of Steam and Thermodynamic Theory of Turbines. By Prof. H. L. Callendar. Pp. xi + 531. (London: Edward Arnold, 1920.) 40*s.* net.

IN this substantial volume Prof. Callendar has set his seal to the experimental and theoretical investigations of the properties of steam on which he has been engaged for many years. By these investigations, which have done much to advance technical thermodynamics, Prof. Callendar has made the engineering world his debtor. It is twenty-one years since he first published, in the Proceedings of the Royal Society for June, 1900, his paper on "the thermodynamical properties of gases and vapours as deduced from a modified form of the Joule-Thomson equation, with special reference to the properties of steam."

With the publication of the book now under review Prof. Callendar's theory comes of age. The book leads up to, and includes, his steam tables, which were issued separately five or six years ago and are accepted as the standard tables, at least by English engineers. Here the author describes, much more fully than before, the basis of the tabular work, discusses its agreement with the latest results of observation, and replies to objections that have been taken to his method on the part of some American writers. Into this controversial matter there is no need to enter here: the replies will have answered their purpose if they succeed in removing misconceptions regarding the scope and character of Prof. Callendar's fundamental work, which, indeed, his own earlier papers can scarcely be said to have presented in a form that made its meaning very clear or its importance obvious.

Perhaps for that reason engineers were slow to appreciate the practical bearing of Prof. Callendar's treatment of the properties of steam. The first of them to do so was Prof. Mollier, of Dresden, himself distinguished for original contributions to technical thermodynamics, who in 1906 published a set of tables and diagrams for steam based on the Callendar characteristic equation. Shortly afterwards the methods of Prof. Callendar and the tables and diagrams of Prof. Mollier were brought to the notice of English engineers by the present writer in the third edition of his book on "The Steam-Engine and other Heat-Engines."

Prof. Callendar's own tables, published in 1915, embody the results of a more complete application of his methods, and make use, in some particulars, of later data. They give all the necessary figures for properties of steam throughout the range of temperature and pressure which is usual in the practice of steam engineering. It is the essence of Prof. Callendar's method to secure results which will be thermodynamically consistent with one another, and will also agree with the results of experiment within a limited but sufficient range. His characteristic equation makes no pretension to be applicable outside that range.

In this respect it differs from characteristic equations such as those of Van der Waals or Clausius. But within the range of its application it gives results the agreement of which with the results of direct observation is as close as the agreement of one set of observations with another.

Prof. Callendar treats steam as a gas the deviations of which from perfection may be expressed by writing the characteristic equation in the form

$$V = RT/P - c + b,$$

where RT/P is the ideal volume of a perfect gas, b is the "co-volume," or volume occupied by the molecules—a volume which is not reducible by lowering the temperature—and c is what he calls the "coaggregation volume," which is the volume lost by the interlinking or pairing of molecules. He treats c as a function of the temperature only, within the range of temperature and density to which the equation applies, making c vary as $1/T^n$. He makes the further assumption that when the pressure is indefinitely reduced the specific heat of the gas is not altered by changes of temperature within that range. These assumptions not only accord with the results of experiment; they also have the great practical advantage of yielding expressions that are easily integrable for all the properties of steam with which the engineer is concerned, such as the total heat, the internal energy, the entropy, the specific heat, the Joule-Thomson cooling effect, and the thermodynamic potentials of Willard Gibbs. Prof. Callendar shows that, by help of his equation and of the assumption which has been stated, expressions for all these quantities are readily obtained by applying the usual thermodynamic relations, and, being so derived, the resulting numerical values, which he calculates for his tables, are necessarily consistent amongst themselves. It was the absence of mutual consistency that was perhaps the gravest defect in earlier tables of the properties of steam.

The range through which the Callendar characteristic equation is applicable may conveniently be described as the range through which the Amagat isothermals (of PV and P) are sensibly straight lines. The slope of these lines depends on the values of the quantities b and c in the characteristic equation: it is, in fact, equal to $b - c$. But to determine the constants of the equation Prof. Callendar relies mainly on experiments of the porous-plug type, which measure the cooling effect produced by forcing the gas through a constricted orifice. In his own experiments of this kind he employed an ingenious differential device which, with his platinum thermometers, went far to eliminate sources of error that affected the somewhat discordant results obtained by other observers. When a gas passes a throttling orifice of any kind, under conditions which prevent loss or gain of heat by conduction, there is one function of its state that undergoes no change, namely, the function which Willard Gibbs represented by the symbol χ. This function is equal to the internal energy *plus* the thermal equivalent of the product PV. It is now usually called the "total heat"—a name first applied to it by Prof. Callendar himself. Its value in technical thermodynamics was emphasised by Prof. Mollier, who introduced charts exhibiting the total heat in relation to other functions of the state, notably the entropy. The "heat-drop," or loss of total heat which the working fluid undergoes in passing through a turbine or engine of any type, is the basic quantity in all calculations of thermodynamic performance. It is equally useful as a means of analysing the reversed thermal cycle that is gone through by a refrigerating machine, for which purpose tables or charts are needed of the total heat of such working substances as carbonic acid and ammonia.

Besides his detailed tables of all the properties of steam, saturated or superheated, within the usual working range, Prof. Callendar gives in this volume an empirical table of the properties of saturated steam up to the critical point, to "serve as a guide for future work." In the extended table the critical temperature is taken as 374° C., in accordance with the results of Traube and Teichner, and the latent heat is calculated by a formula of the Thiesen type, which makes it vanish at the critical point. The critical volume becomes 3·25 c.c. per gram. The critical state lies, of course, far outside the region within which Prof. Callendar's characteristic equation is applicable. He deals with it in a separate chapter, which includes an interesting discussion of recent experiments on carbonic acid by Jenkin and Pye.

Another section of the book deals with the theory of flow through nozzles and of the steam turbine. In this field also Prof. Callendar's work has been of fundamental importance by showing that the conditions of adiabatic flow are not, in general, equilibrium conditions, but involve complications due to supersaturation. By taking account of the effects of supersaturation he has brought the theory of steam-jets into harmony with the results of observation, removing what had been a puzzling discrepancy and explaining why it is that the measured discharge from a nozzle is actually greater than the limit which, according to the older theory, would be found even under frictionless conditions. The same

considerations are here applied to the analysis of what occurs in the steam turbine as a whole.

The book is completed by three appendices; the first is on general thermodynamic relations, and the second is on the use of a steam diagram in which the co-ordinates are the total heat and the logarithm of the pressure. The third appendix gives the steam tables in the same form as that in which they were separately presented in his earlier publication.

It is not a book for beginners: it will be intelligible only to those who have a working knowledge of general thermodynamics and are fairly familiar with the use of partial differential coefficients. But engineers and physicists who have this equipment will find it a valuable work of reference. They will welcome so detailed a statement of original views and methods from one whom they gratefully recognise as a leader and a pioneer. Prof. Callendar writes with the authority of an investigator whose knowledge of steam and its properties is probably unique.

J. A. EWING.

Ore Deposits of Utah.

The Ore Deposits of Utah. By B. S. Butler, G. F. Loughlin, V. C. Heikes, and Others. (U.S. Geol. Surv. Professional Paper 111.) Pp. 672+lvii plates. (Washington, D.C.: Government Printing Office, 1920.) 1½ dollars.

THE series of monographs in preparation by the Geological Survey of the United States to summarise existing knowledge of the ore deposits of the separate American States will render readily available much valuable information now dispersed through a voluminous and scattered literature. The first of the series was on New Mexico (1910). The second deals with Utah, an area of special interest as regards both its geological structure and the variety of its ore deposits. The study of Utah has introduced many new conceptions into structural geology; some of them, like that of the laccolite, a term introduced for the Henry Mountains by Gilbert, have been fully confirmed; others, such as the support to antecedent rivers by the oft-quoted case of the Green River, have been set aside by fuller knowledge of the facts, or, like the igneous sequences proposed by Dutton and Spurr, are dismissed as too uncertain.

Utah has given exceptionally clear evidence of the importance of block faulting in determining the existing relief, and of the cause of such faulting by subsidence after long periods of igneous activity and earth movement. The views of le Conte and Suess, based on the earlier studies of Utah, are fully justified by the latest contributions to its geology. The tectonic history of the region presents a significant coincidence with that of Africa in the importance of east-to-west folds in the late Cretaceous, and of subsequent north-to-south faults that may be even still in progress.

The economic geology of Utah is especially instructive on account of the remarkable variety of its ore deposits. Some, such as the silver sandstones, are well known owing to the controversy as to the origin of the ores; the authors of this survey adopt Lindgren's conclusion that they were sedimentary grains concentrated by hot water in consequence of the igneous intrusions. Probably the most valuable general conclusion in the volume (pp. 196–201, and the instructive diagram, Fig. 31) is that the quantity of the ore deposits beside masses of intrusive igneous rock depends on the lowering of the surface by denudation. This principle had been previously used to explain the contrast between the gold veins in the adjacent fields of Bendigo and Castlemain in Victoria, and also the fact that the ores beside the granites of Burma are richer beside narrow than beside the wider outcrops. It receives its fullest and most authoritative expression in this volume. The clearness of the diagrammatic figures of the ore bodies and tectonic structures is an especially notable feature of this important and well-executed monograph.

Medical Science and Practice.

(1) *Obstetrics: Normal and Operative.* By Prof. G. P. Shears. Third edition, revised by Dr. P. F. Williams. Pp. xxii+745. (Philadelphia and London: J. B. Lippincott Co., 1920.) 35s. net.

(2) *Principles and Practice of Operative Dentistry.* By Dr. J. S. Marshall. Fifth edition. Pp. xxix+711+xvi plates. (Philadelphia and London: J. B. Lippincott Co., 1920.) 35s. net.

(3) *Diagnosis and Treatment of Brain Injuries: With and Without a Fracture of the Skull.* By Prof. W. Sharpe. Pp. vii+757. (Philadelphia and London: J. B. Lippincott Co., 1920.) 35s. net.

(4) *Lippincott's Quick Reference Book for Medicine and Surgery.* By Dr. G. E. Rehberger. (Philadelphia and London: J. B. Lippincott Co., 1920.) 63s. net.

MESSRS. LIPPINCOTT'S series of text-books on medical subjects is well known in this country. Many of the volumes, as is the case with two of the four under review, have already reached the third or later editions.

Like nearly all American books, they are

copiously illustrated, and most of the pictures are helpful. A great many are borrowed, as may be judged from a list of between two and three hundred acknowledgments in Prof. Shears's book. Among these figures are four of a condition which, says the author, "one reads about but does not see"! Prof. Sharpe in his work uses photographs abstracted from kinematograph series to illustrate the stages of an operation and also the gait in spastic palsies of cerebral origin; the method is interesting and perhaps useful. The reproductions of microphotographs of dental tissues, normal and diseased, given by Dr. Marshall in his work on dentistry are really very good.

(1) and (2). Two of these books, those on obstetrics and dentistry, are text-books "for the student and practitioner," and both suffer a little from their dual aim. Whilst not large enough for works of reference, there is a tendency to include mention of methods or procedures but little used or of doubtful value, lest the author should appear "not up to date." The practitioner, therefore, must make use of larger or more specialised works, while the student is distracted from essentials and perhaps conceives wrong ideas of proportional values. The fault is by no means peculiar to these volumes—it pervades very many similar publications—which are, in fact, both very readable, for they are founded on extensive personal experience. With them as guide the student will not go far astray in practice, but it is just questionable whether the British student would do well to face his examiners without other help.

(3) Prof. Sharpe's book is not quite in the same category. It, too, is founded on personal experience; it embodies a large number of case records and might almost be called a thesis on the use of subtemporal decompression as a routine treatment in the presence of undue intracranial tension. In this country Harvey Cushing is looked upon as the exponent of this operation as to both indications and technique, and it is a little surprising not to find here a more ample acknowledgment of his pioneer work. The author's advocacy of the operation, at any rate in the birth palsies of children, in preference, apparently, to attack nearer the known site of the lesion, will scarcely suffice to secure a verdict in his favour from a jury of British surgeons. His documents, however, demand and deserve study by specialists. He is probably right in his view that recent severe injuries of the brain are too often treated on the principle of wait-and-see, but his method of demonstrating a long-persistent, high cerebro-spinal pressure seems a little inadequate. The accepted physiological view of the maintenance of normal pressure and of the feasibility of modifying it by surgical measures must be altered, if the operation of decompression undertaken months or years after the injury be indeed sufficient to accomplish so much amelioration of symptoms. Nevertheless it makes a very interesting book.

(4) The last book on the list is a little difficult to place, at least for the British public, if not for the American. It is a large and expensive work, alphabetically arranged in eleven sections which are indicated by lettering in incised spaces at the free margin. The frontispiece is a folding manikin of value only to the layman, whilst the eleventh section consists of a hundred pages of pharmacology and therapeutics of use only to the practised and practising physician.

There is necessarily a lavish use of cross-referencing which is sometimes irritating; to be sent from "myotonia congenita" to "amyotonia congenita" only to be referred to "dystrophy" is annoying. It is obviously impossible to cover the whole range of medicine, surgery, and the specialties, such as eyes, skin deformities, nasal and aural surgery, gynæcology, obstetrics, and genito-urinary diseases, in one volume, however bulky it may be.

After all these complaints, when one comes to the subject-matter it is impossible not to appreciate the skill with which the "quick reference" book has been compiled, or to overlook the immense industry that has enabled Dr. Rehberger to skim the cream of all recent work and to present a mass of information in which it is difficult to detect a serious error. Moreover, when a controversial statement slips in, there is always a name or a reference to take the onus.

Compendia are not looked upon with much favour by those responsible for teaching, but probably there is a demand for such a book by busy practitioners, and it would not be surprising if even the well-informed and well-read should find it handy.

Our Bookshelf.

Chemie der Hefe und der alkoholischen Gärung. By Prof. H. Euler and Prof. P. Lindner. Pp. x+350+2 Tafel. (Leipzig: Akademische Verlagsgesellschaft m.b.H.: Gustav Fock, 1915.)

HORACE BROWN, in his charming reminiscences, maintains the thesis that it is to the study of the processes of brewing and other fermentation industries that we owe many of the advances which have so greatly extended our knowledge in the domains of preventive medicine, modern

surgery, and sanitation. Be this as it may, and there is much to be said for it, there can at any rate be no doubt that yeast has been more thoroughly studied than any other micro-organism—and from the most diverse points of view. The book under review gives a clear and comprehensive account of these investigations, written by men who are peculiarly fitted for the task by their long experience in different branches of the subject. To Prof. Lindner fall the chapters on morphology, classification, and cultivation, whilst the remainder of the subject—the chemistry of the cell contents, the enzymes, and the energy relations—is dealt with by Prof. Euler.

Turning over the pages and remembering that the date of the book is 1915, one cannot help being struck by the great activity which is still being shown in research on this subject, and by the many notable additions which will have to be included in any new edition. The stream of work which has flowed uninterruptedly since Buchner laid bare the secret of zymase shows no signs of shrinking, but rather increases in volume year by year. Fresh facts are constantly being discovered and fresh light thrown on related subjects. At the moment the centre of interest and discussion is shifting from alcoholic fermentation, over which it has long rested, to the important problems raised by the nutrition of yeast and by the abundant production in the yeast-cell of one of those mysterious dietary essentials, the vitamins. In this connection many early observations were made concerning yeast, culminating in the experiments of Wildiers, who in 1901 postulated the necessity for a substance of unknown nature—which he termed "Bios"—for the growth of yeast. Some investigators have identified this with the vitamin B (water-soluble B factor) of McCollum, and an interesting controversy has arisen over the question. Another instance of the inexhaustible vitality of the subject is thus afforded, and it can be asserted with confidence that we are far from the end, perhaps rather only at the commencement, of the biochemical discoveries originating in the study of yeast. A. HARDEN.

The Man who Did the Right Thing: A Romance of East Africa. By Sir Harry Johnston. Pp. vii + 444. (London: Chatto and Windus, 1921.) 8*s*. 6*d*. net.

THE man who did the right thing, and (except for one moral lapse, not of his own seeking) continued to do the right thing to the end of the chapter, was, as one might expect from a narrative so naïvely autobiographical as this "romance," an African pioneer, explorer, naturalist, and proconsul. The scene is laid in East Africa, mainly in the missionary field, and the period covered in the narrative dates back to the entry of Germany into the race for territory that led to the partition of Africa. Apart from the underlying love-story, which does duty for the sub-title, this novel of adventure (in treatment as well as in action) is remarkable for its fidelity to detail and its trenchant analysis of character. To those who know something of the environments and are acquainted with the types of the leading actors in this story—not excluding the author—the interest is unflagging and the appeal irresistible. Truly it is a section cut out of real life, transparent and convincing. Names are unnecessary. The mordant criticism of officials in "the Service" (F.O. and C.O.), frankly contrasting with efficient German representatives, in the opening up of East Africa to European diplomacy, is further emphasised by the hero taking service as director (Herr Direktor !) in an Anglo-German undertaking for the exploitation of a certain concession, known as "The Happy Valley," somewhere in the Kilimanjaro region, and thereby achieving a remarkable success.

It is a book well worth reading for its information no less than for the story it tells. We confess, however, to some irritation at the originality of the author's treatment in places—*e.g.* his abrupt changes of mood and tense, and the actual "staging" of some of his lengthy dialogues, as in a play. A. S. W.

Artificial Light: Its Influence upon Civilization. By M. Luckiesh. (The Century Books of Useful Science.) Pp. xiv + 366. (London: University of London Press, Ltd., 1920.) 12*s*. 6*d*. net.

MR. LUCKIESH, who is well known as the author of a number of works upon illumination of a somewhat technical nature, has in this new volume written an interesting popular account of the development of artificial lighting. The influence of light upon civilisation is a fascinating subject. The author traces its early origins in the initial chapters of the book, which are illustrated by photographs of primitive pine-splinters, oil lamps, etc., and alludes particularly to its use as an element in religious ceremonial. Other chapters deal with early gas lighting, electric incandescent lamps and arcs, and the "light of the future." Later various applications of light—domestic, industrial, and spectacular—are discussed, and a chapter is devoted to artificial light in warfare. The type and paper are excellent, and there are insets of some remarkable photographs of lighting installations. The concealed lighting of the statue of Liberty in New York harbour forms an appropriate frontispiece, while several of the views of street lighting are striking; perhaps the most pleasing of all is a view of the Panama-Pacific Exposition at night. Generally speaking, the author has dealt with developments and applications of lighting in a popular manner rather than attempted a detailed analytical study of its effect upon civilisation, though the figures tracing the progressive diminution in the cost of light and its influence on health, safety, and efficiency are instructive. In the final chapter, entitled "Light—A Fine Art," the author writes with enthusiasm on the applications of light and colour for spectacular and decorative purposes. At the end of the volume a series of references to works on illumination and an adequate index are provided.

Letters to the Editor.

Human and Other Tails.

IN NATURE of February 24 last, p. 845, there appears a report of Prof. Arthur Keith's remarks at the meeting of the Royal Anthropological Institute held on February 8. It may be that the Journal of the institute will contain a more detailed paper on the same subject, and that the fuller paper will somewhat modify the dicta put forward in the report as it appears in NATURE. But in the absence of any further details it seems worth while to note some of the points raised by Prof. Keith which appear open to criticism.

My right to criticise may perhaps be sustained by the reference on p. 846 to Tarsius and to my published views concerning its systematic position. Prof. Keith's rather far-reaching generalisations were called forth by the examination of one of those fleshy sacral appendages commonly known as human tails. It is obvious from every sentence in the article cited that Prof. Keith believes that the human tail was lost because man became an orthograde—that is, adopted a vertical instead of a horizontal poise for his body. No doubt that is a very well justified position to take up, and, in so far as a human orthograde poise implies a cessation of tail utility, I entirely agree with him. But when Prof. Keith says, "With the evolution of the upright posture the pelvic muscles which act on the tail had to bear the steady burden of the abdominal viscera—had to be in action as long as the orthograde posture was maintained. They could not serve in the support of the viscera and the movements of the tail at the same time," I dissent from him altogether. Indeed, to me it seems a remarkable thing that one who is in constant association with the museum of John Hunter could possibly believe that, if this dual duty of support of viscera and production of tail movements were thrust upon them, the muscles would fail in one respect or the other. We need, as a matter of fact, go no further afield than the kangaroo to see how an animal which is typically orthograde may support its abdominal viscera in the upright posture, and yet possess a tail which is one of the most wonderful of muscularly controlled caudal appendages met with among the mammals.

Man has not lost his tail because the caudal musculature is incapable of undertaking the dual *rôle* of visceral support and caudal mobility. He has lost it because it has ceased to be of any use to him. For the same reason the gibbon, the orang, the chimpanzee, and the gorilla have lost theirs. For the same reason certain "pronograde apes" (which Prof. Keith appears to assume possess uniformly "basal or pelvic," as well as "free or terminal," portions of their tails) have lost theirs. Cynopithecus possesses no more than a button, the Barbary ape still less, and, indeed, the reduction of the tail is seen to the best advantage in the most typically pronograde group (the baboons) of the Primates. Because the tail has ceased to be of any functional use certain of the lemurs have also lost it, and so have a host of other mammalian forms belonging to other orders. Did it not appear flippant, one might ask if Prof. Keith imagines the guinea-pig lost its tail because its caudal musculature could not fulfil a dual *rôle*. Recession of the tail has been effected, and prehensile tails have been developed, over and over again in the mammalian phylum. But one may not argue phylogeny, or the limits of the possibilities of muscular adaptation, to account for these things. No argument which bases the loss of the tail on the grounds cited by Prof. Keith carries the least conviction or bears any interpretation which may be distorted into human phylogeny.

Prof. Keith further goes on to state that "in pronograde apes the pelvic visceral musculature is attached to the peculiar chevron-like bones (hæmal arches) placed beneath the pelvic vertebræ of the tail; the reappearance of the hæmal arches in the human embryo during the second and third months of development may be regarded as definite proof that man comes of a pronograde ancestry." This is a common type of argument, one that has been current far too long, and one against which I have been attempting to teach for some time past. Apart from the confusion that may be caused by identifying "hæmal arches" with definite "chevron bones" is the gross fallacy involved in the argument that because hæmal arches are present in pronograde apes and in man, therefore man is developed from a pronograde ape. Hæmal arches are a primitive vertebrate heritage, but they are no more; they have no more to do with the pronograde poise *per se* than have the neural arches or the gill bars. We all know that the pronograde habit is typical of lower vertebrates, and we need not quibble about a pronograde vertebrate ancestry for man. But to argue that the pronograde simian ancestry of man is evidenced in the "reappearance of the hæmal arches in the human embryo during the second and third months of development" is sheer nonsense. Hæmal arches are developed in birds, and one would have as good justification for saying that this proved that man descended from a volant ancestor as Prof. Keith has, by the parallel argument, for claiming man's descent from a simian pronograde ancestor. Both arguments are fallacious and stupid.

Whilst the whole trend of Prof. Keith's remarks appears to be directed towards a vindication of the pronograde simian ancestry of man, he seems, in the end, to disagree with the ancestral position of "*Tarsius spectrum*, for which Prof. Wood Jones claims a special human relationship." Yet of this animal he says: ". . . in its tail and tail-musculature Tarsius is a pure pronograde Primate." I should be sorry to destroy the last bridge by which Prof. Keith's views might be reconciled with my own; but I have no hesitation in saying that Tarsius is certainly not a pure pronograde, and that, moreover, no living animal the habits of which are open to observation should be judged as a pronograde by an examination of the musculature of its tail.

F. WOOD JONES.

The University, Adelaide, South Australia,
April 10.

TWENTY-FIVE years ago it was my privilege to teach Prof. Wood Jones; he now repays me with interest and with some degree of vigour. The matter wherein we differ has a very direct interest, not only for those who are seeking to unravel the history and relationships of man by means of anatomical evidence, but also for every zoologist who relies on structural details for arranging animals in a natural or evolutionary series. In man and in the four anthropoid apes—the gorilla, chimpanzee, orang, and gibbon—the tail has undergone a peculiar transformation—a sacralisation it may be named—for its vertebræ have become a mere submerged appendix of the sacrum. The depressor muscles of the tail have become spread out to form a muscular hammock on which the pelvic

viscera are supported. With this sacralisation of the tail there are numerous correlated changes in the vertebræ and muscles of the spine, in the musculature of the body-wall and thorax, and in the shape and arrangement of the viscera of the body-cavities.

As will be seen from his letter, Prof. Wood Jones is of opinion that each member of this orthograde group of Primates—man, gorilla, chimpanzee, orang, and gibbon—has acquired the sacralisation of the tail independently of each other; in his opinion we are dealing with remarkable resemblances produced by convergence. On the other hand, it seems to me a more rational explanation to believe that evolution is true, and that all the orthograde Primates are the progeny of a common stock—the primitive orthograde stock—and that we are therefore dealing with a common inheritance. Seeing that all have a nervous system cast in a common mould, with vascular, alimentary, muscular, and bony systems which differ only in detail, we do much less violence to what we know of the laws of evolution by adopting my explanation than if we accept that offered by Prof. Wood Jones. In no other Primate, save the five mentioned above, has the tail undergone sacralisation. The guinea-pig, the Barbary ape, and Cynopithecus have no bearing on the point in question; their tails have not undergone sacralisation. To compare the posture and method of progression of the kangaroo to man or an anthropoid ape is of the nature of burlesque.

In my original paper on vestigial tails I made special allusion to Tarsius because Prof. Wood Jones has misled public opinion as to the structural relationship that exists between anthropoid apes and man. He holds, on what I consider a flimsy basis, that man has been evolved from a Tarsius-like ancestor, and that between this ancestor and man there must be a series of undiscovered links. Tarsius has a particularly long tail; in no sense can its posture or method of progression be said to be like that of the orthograde Primates. In the manner in which its tail-muscles are arranged Tarsius resembles pronograde or dog-like apes. It has no claim to be called humanoid, whereas in this, as in a thousand other structural characters, the anthropoid apes can claim, not a resemblance, but an identity. Arthur Keith.

The Stationary H- and K-lines of Calcium in Stellar Atmospheres.

It has been noticed by many observers that the space surrounding early B-classes of stars (*e.g.* δ Orionis) often show absorption of H- and K-lines of calcium, which do not share in the Döppler displacements of the other absorption-lines of the stellar spectra. This suggests that these stars are enveloped in an atmosphere of calcium vapour which does not partake in the orbital motion of the stars (Nature, April 21, p. 247).

There is, of course, naturally a difficulty in realising why calcium, alone of all elements, should be found to occur in the attenuated atmospheres surrounding a stellar system. Very closely connected with this phenomenon is the observational fact that in the flash-spectrum of the sun the longest arcs are those corresponding to calcium H- and K-lines, indicating that in the sun also the outermost layers (according to Mitchell, 14,000 km. above the solar disc) are composed of calcium. Hydrogen, the lightest of elements, which we should expect to occur in the highest layers, disappears at a much lower level (8000 km., according to Mitchell).

The problem is naturally a complicated one, but I think that a way to solution is afforded by the theories of selective radiation-pressure and of the temperature-ionisation of gases advanced by me in the following papers:—"On Radiation Pressure and the Quantum Theory" (*Astrophysical Journal*, September, 1919); "On Selective Radiation Pressure, etc." (Journ. Coll. of Science, Calcutta, 1920); "Ionisation in the Solar Chromosphere, etc." (*Phil. Mag.*, vol. xl., 1920); and "On a Physical Theory of Stellar Spectra" (Proc. Roy. Soc. Lond., May, 1921).

According to these papers, the H- and K-lines are the resonance-lines of Ca^+, *i.e.* of a calcium-atom which has lost one electron. The resonance-line of neutral calcium is the *g*-line, $\lambda = 4227$. In the Fraunhofer spectrum we get H, K, and *g*, showing that in the solar photosphere calcium is largely ionised owing to the high temperature prevailing there. At higher levels, owing to diminution in concentration, the ionisation becomes complete, so that the *g*-line disappears entirely, leaving only the H- and K-lines.

The sun is a dwarf star of the Go class, corresponding to a surface temperature of 7000–7500° K. When we consider the spectra of the still hotter stars, classes F, A, and B, we find that the *g*-line becomes fainter and fainter, until it disappears altogether from the B8A class. In the still hotter stars we have only the H- and K-lines, showing that they do not contain neutral calcium at all, but only ionised calcium.

This explains the varying behaviour of the *g*-line and of the H- and K-lines, but we have still to determine the force which drives Ca^+ to the outermost layers. It is natural to conclude that the forces which are responsible for driving calcium absorbing H and K to the greatest height in the solar atmosphere are also responsible, in the case of stars having a larger surface temperature, for driving calcium to the surrounding parts of space. Now what can this force be, and why should this show a preference for calcium?

In the case of the sun I have attempted to show that this force is furnished by the pressure of radiant energy from the solar disc acting in a selective way upon the Ca^+-atoms. The term "selective" is most important here, and requires an explanation. Radiation-pressure is due to absorption, and therefore, in the case of a gas illuminated by white light, only those pulses which the gaseous atom is capable of *most frequently absorbing* are effective in producing pressure. A gas can usually absorb lines of the principal series alone, but the lines of the subordinate series are absorbed only in exceptional circumstances, and even then to a much smaller extent; so that the maximum lifting effect of radiation-pressure is to be expected only in the case of atoms absorbing the resonance-lines. (For more detailed arguments see the papers above-mentioned.) In addition to this, the lifting force would depend on the intensity of the region corresponding to the absorbed lines in the spectrum of the continuous background of white light, and on the solid angle subtended at the atom by this background.

In the case of the sun the surface temperature is 7300–7500° K (Biscoe, *Astrophysical Journal*, vol. xlvi., p. 355), so that, according to Wien's law, $\lambda_m T = b$, the maximum of emission lies at $\lambda = 3920$ Å.U., very close to the H- and K-lines of Ca^+. Also these lines are the resonance-lines of Ca^+, so that we have here the maximum effect of selective radiation-pressure. The resonance-line of hydrogen is at $\lambda = 1216$ Å.U., and therefore the effect of radiation-pressure is extremely small.

It is not possible to say whether the lifting power

of selective radiation-pressure alone is capable of neutralising the force due to the gravitational attraction of the sun, but it looks very much as if this were so. Without being dogmatic on this point, we can work out the consequences of this assumption. In the case of stars having a much larger surface temperature, say 14,000° K, B8A class, the value E_λ for H- and K-light would be much larger, so that the radiation-pressure is still greater, and in some cases preponderates over the greater value of gravitational force on these stars. Thus Ca+-atoms would be driven very far into the surrounding space. They will be prevented from absolutely leaving the system, because with increase of distance the solid angle subtended by the disc of the star at the atom would diminish, and a condition of equilibrium would at last be reached.

The same phenomenon occurs to a smaller extent, in the case of the sun, with Sr+ and Ba+, which have their resonance-lines near the spectral region of maximum intensity, but owing to their greater atomic weight the compensation is not so marked. Still Sr+ is very prominent in the chromospheric spectrum, rising to a height of 6000 km.

The question may be asked: Why do we not obtain the same phenomenon in the case of the other light elements? These can be divided into two broad groups: (1) non-metals like H, He, N, O, Ne, and A, having a high ionisation-potential, of which the resonance-lines lie in the extreme ultra-violet—*e.g.* for H, at $\lambda=1216$ Å.U.; for He, at $\lambda=585$ Å.U. (Lyman and Fricke, *Phil. Mag.*, May, 1920)—and can be detected only by subordinate lines—for helium, by D_3, $2p-md$; for hydrogen, by the Balmer lines. Naturally the effect of selective radiation-pressure is small on these elements. (2) Elements like Na, K, Mg, Al, Sc, Ti, Fe, which have an ionisation-potential varying from 5 to 8 volts. Under the conditions treated here these are mostly ionised, but the resonance-lines of these ionised elements lie mostly outside the region available for observation, *e.g.* the resonance-lines of Mg+ are $\lambda=2795{\cdot}5$, $2802{\cdot}7$. The resonance-lines of Na+ and K+ have not yet been discovered, and probably lie in the extreme ultra-violet. Sc+ and Ti+ are represented by prominent lines in the chromospheric spectrum, but it is not yet known whether these are resonance-lines of these elements.

The hypotheses thus appear to be promising, but nothing final can be said before we can calculate the absolute value of the selective radiation-pressure on an atom. According to Eddington (Monthly Notices, R.A.S., 1920, vol. lxxx., p. 723), the absolute value of the radiation-pressure is too small to account for the total neutralisation of gravitational force on the sun; but in that paper the consequences are worked on the basis of the continuous theory of light. The foregoing line of investigation at least brings out the intimate connection between the stationary character of the H- and K-lines in the space round the stars and the great prominence of these lines in the chromospheric spectrum. It shows that the higher chromospheric levels, as well as the space round B- and A-stars, may probably contain, besides Ca+, also Na+, K+, Sc+, Ti+, and Mg+, but owing to the fact that our observations have to be limited between $\lambda=3000$ Å.U. and 6000 Å.U., and that none but the resonance-lines of Ca+ lie within this region, we can detect nothing but Ca+. But if some day we can overcome the limitation imposed by atmospheric absorption, probably we shall be able to detect Li+, Na+, Mg+, K+ in the atmospheres surrounding B-stars which show stationary H- and K-lines.

Biological Terminology.

MY gentle touch has started an avalanche indeed, but I remain unmoved. Sir Archdall Reid asks (NATURE, June 2, p. 425): "Is not all systematic zoology and botany founded on this kind of classification?"—a classification based on definite, concrete facts of structure, in which there is "little or nothing" based on causes, on antecedents and consequents, or on hypothesis. The answer is in the negative. May I illustrate briefly some kinds of interpretation that a systematist has to employ?

There lie before me some mushroom-shaped objects from the Permian of Timor, clearly echinodermal, and actually described as the swollen spines of a sea-urchin. Such a spine is normally attached to the shell of the urchin by a ball-and-socket joint. These bodies, however, present at the end of the stalk three articular facets, each with a straight fulcral ridge, so placed that the fulcral ridges form an approximately equilateral triangle. Now, setting all resemblances aside, it is obvious that a single appendage cannot be attached to an immobile base by three facets so disposed, because the result of such an arrangement is immobility. It follows, from equally clear mechanical principles, that each facet must itself have borne a single appendage. Consequently the mushroom-like body is not an appendage, but a base which once bore three appendages. In short, it must be the cup and base of a crinoid. Having reached this conclusion by the application of mechanical principles, one attempts to apply some test, even if not a crucial test in the strict sense. The stereom of a spine is relatively light, and the meshwork in the axial region is still more open; the stereom of a fused crinoid base is dense. Sections across the Timor fossil show that its stereom is of the latter character. Not until all the facts have thus been interpreted can we proceed to apply the methods of a postal address and deliver our fossil at its proper street and number in Crinoid-town.

But there are cases in which the address is almost illegible, or has been so often crossed through and re-written that recourse must be had to skill higher than that of a letter-carrier. I am at the moment trying to identify some fossil Blastoids from North America. Of recent years the rocks in which these genera are found have been so minutely subdivided and the species have been so finely discriminated that the ordinary descriptions and keys (postal directories) cease to be of much help. In this class, as in others, the same forms appear to recur at intervals of time, and a correct interpretation demands a close study of the development in correlation with the chronology; by applying, as others have done, the theory of recapitulation we may unravel the tangle. It is not only fossils that furnish such problems to the philosophic interpreter; Dr. Annandale was showing me yesterday some Gastropods from Asiatic lakes that have to be dealt with in just the same way.

If we turn to the broader divisions of systematic zoology we derive still less aid from those simple rule-of-thumb methods which represent to Sir Archdall Reid the principles of taxonomy. At every step the modern systematist is considering origins; for him the truth or falsity of such principles as "the irreversibility of evolution" is of vital importance; his very diagnoses embody speculations. But the systematist recognises the metaphysical nature of his classifications, and he is perpetually seeking some crucial instance that shall give them a more secure basis of fact. He prophesies, for example, the existence of some connecting type at a certain period, and then he goes and finds it.

So much for the systematist! As for the biologist

at large, I do not believe he is averse from employing crucial tests. His difficulty in the manifold processes of life is to formulate tests that really are crucial. Sir Archdall Reid thinks it an easy matter, and he takes recapitulation as an instance. At the moment when his letter was published some of us were discussing that very question at the Linnean Society, and Sir Archdall Reid, had he been present, would have seen that the issue was far from being the simple one that he imagines. F. A. Bather.

A New Acoustical Phenomenon.

When living near Croydon aerodrome during the earlier part of the war, I noticed that the higher-pitched sounds apparently given out from an aeroplane flying nearly overhead varied with the height of my ear above the ground; thus, by bending down to one-half one's normal height, the pitch of this higher note rose an octave. I have on many recent occasions confirmed this result. This phenomenon is most noticeable when standing on a smooth road or lawn, and is scarcely distinguishable on a rougher surface, such as a hayfield; the logical conclusion is therefore that it is due in some manner to reflection from the ground. The pitch of the note varies also with the angle of elevation of the aeroplane, and is not generally audible unless this is more than about 45°. Since the pitch rises continuously as the head is lowered, the apparent explanation is that the note is due to the interval between the arrival of the direct and reflected waves from impulses radiated from the aeroplane—that is to say, no note of this definite pitch comes through the air from the aeroplane, only a regular, or irregular, succession of impulses, the time periods of which have no relation to the observed note, for it is obvious that merely bowing to the aeroplane could not alter the pitch of any note it might be giving out. (It is well known that a note of much lower pitch, due to the engine, is always present, but it is not in this sound that the variation takes place, although it is possible that these are the waves from which the variable high note is produced by reflection.) The pitch of the sound with which we are concerned is thus due to the fixed interval between the arrival of the direct and reflected impulses, and thus depends upon the height of the observer and the angle of elevation of the aeroplane. An interesting deduction from the discovery is that the ear is able to appreciate pitch from a succession of double impulses, if the interval between the elements of each double impulse is constant.

The phenomenon is not in any way peculiar to aeroplane noises; I have observed it with equal distinctness, though the sound was fainter, when standing under an aspen tree in a light breeze. Through the rustle of the leaves could be distinguished a note of quite definite pitch, which, as before, rose to its octave on lowering the head to half one's height.

In support of the explanation I have given, it may be remarked that the pitch of the note observed seems to correspond with the interval of time between the arrival at the ear of the direct and reflected impulses as calculated from the velocity of sound in air.

From the physiological point of view it would be interesting to make a laboratory test, using a disc siren with the holes pierced in groups of two, all pairs being similar to one another, but grouped at unequal spaces on the circumference; thus the passage of each pair would give a double puff, but the double puffs would be in an irregular succession. This would, no doubt, give a definite note corresponding in pitch to the interval between members of a pair of holes, and would be a further confirmation of my explanation.

That two impulses alone appear to give a sense of definite pitch is interesting, and seems to indicate the existence of a resonating system in the ear. Experiments such as I have suggested, with a disc siren, might therefore help in the solution of the much-discussed problem of the function of Corti's organ. Another and more general series of experiments would have the object of finding whether, as is indicated by my observations, all sounds when heard by an observer near a reflecting surface have, in addition to the incoming fundamental note, a note of a pitch depending on the distance of the observer from the reflector. This phenomenon is known to have occurred, as regards electric waves, in Hertz's classical experiments. Unfortunately press of other research work prevents me from carrying out tests in this fascinating subject, but perhaps someone more directly interested may find time to develop it further.

Herons and Fish.

It was commonly believed and asserted by old-time writers on natural history that from the feet and legs of the common heron exuded an oil with a peculiar odour which attracted fish within striking distance of the bird's powerful beak. Anglers used to mix the fat of a heron with flour and other matter and anoint their baits with it, whereby, says John Jonston in his "Historia Naturalis" (1657), "mirifice pisces illiciuntur."

I have never regarded this theory as of greater value than many others propounded by medieval empirics, but it was recently brought vividly to mind by what has taken place in the garden of one of my country neighbours. In this garden there is a rectangular pond measuring about 30 ft. by 20 ft. The sides are of dressed masonry, which extends under 9 in. of water so as to form a continuous ledge a yard broad, beyond which the depth drops suddenly to between 3–4 ft., wherein some of Marliac's water-lilies are grown. The pond was stocked with goldfish, which throve well until a heron found its way there, and has succeeded in exterminating them. The owner of the garden, a good observer upon whose statement I can rely, tells me that the bird always took its stand in one corner of the pond, on the ledge covered by the shallow water, and that the goldfish moved out of the deep water into the centre and congregated round the heron, who picked them up at leisure. Had the fish remained in the deep water which they usually inhabited, of course the heron could not have reached them.

Although I draw no inference from this incident, it seems worth mentioning. It would be interesting to hear of an authentic parallel case.

Monreith, Wigtownshire.

Why do Worms Die?

Many times during the last twenty years I have been tempted to make the following communication. My house backs on to, and is partly built into, the old cliff at St. Leonards-on-Sea, and my back door opens on to a road cut into the face of the cliff. The road is well tar-macadamed and watertight. The esplanade at St. Leonards is wide, tar-gritted, and

watertight, and it contains a number of ornamental flower-beds surrounded by low brick and cement walls, surmounted by cornices which overhang 2–3 in. The surfaces of the beds are about 12 in. below the top of the walls.

On certain occasions I find worms in the back street, generally of medium to a rather large size, which have the appearance of being "drowned," although it is very rarely that life is extinct. On the esplanade they are present in large numbers. They occur at all points between the beds and the sea-wall, over which many of them must pass, for one can find them on the watertight stone undercliff. One naturally expects worms to rise after rain, but in a wet season I have known eleven wet days in succession without a single worm appearing, while on the twelfth day large numbers were to be found on the pavements, the road, and the back street. On the other hand, I have known them to occur after a rainstorm following dry weather. In several years the dates in November and January have coincided. The first thing that strikes one is that the phenomenon occurs only at long intervals, and then such large numbers participate in it. At other times one may never see a single worm. I have often wondered if it were in response to a migratory instinct.

The mystery is how these worms mount a wall 12 in. high and negotiate the overhanging cornice. On several occasions I have known quantities of "whitebait" and other things that occur at the surface of sea-water similarly strewn upon the esplanade and roads, and I have been tempted to ask if these worms have not been caught up similarly and returned to earth with the rain. W. J. Lewis Abbott.

I think Sir Ray Lankester (Nature, June 2, p. 424) will agree with me that earthworms when underground must frequently or usually be in contact with other moist surfaces. My impression is that in dry weather, when the upper layers of soil contain only adsorbed water and are what we call "dry," earthworms seek the lower layers where the particles are moist—that is, are surrounded by a surface film of liquid water, however thin this may be. When in such a moist layer the surface of the worm must at many points be obtaining its air-supply through the medium of water which is not part of itself. The air, as Sir Ray Lankester says, reaches the worm through the porous soil, and I think in part through the moisture on the surface of the particles. The statement in my letter in Nature of May 19 can admittedly be read as implying that the worm was partly dipped in slime or mud, but this was far from my meaning. J. H. Coste.

Teddington.

Vitality of Gorse-seed.

By way of supplementing my letter to Nature of September 26, 1918 (vol. cii., p. 65), on the above subject, it may be of interest to record the fact that the seedlings arising from seed which has lain dormant in the soil for a quarter of a century have produced vigorous plants. A small part of the 20-acre field was not reploughed owing to its steepness, and the gorse seedlings which came up on it after the war-ploughing of the winter 1917–18 have been allowed to grow. They are now in their fourth season of growth, and are good-sized bushes averaging 2 ft. in height, which have been this spring a mass of bloom, like the gorse generally in this district and, I believe, throughout the country.

I can also add another year, making twenty-six in all, to the vitality of buried gorse-seed; the field in question, save for the above-mentioned steep slope, was reploughed in the winter 1918–19, with the result that a fresh crop of gorse seedlings appeared the following summer. The field has now reverted to grass, and these two-year-old seedlings are being grubbed up. John Parkin.

The Gill, Brayton, Cumberland, June 3.

Habits of the Hedgehog.

In the article on the hedgehog which appeared in Nature of May 19, p. 375, mention is made of the widespread belief that hedgehogs suck the teats of cows. Although farmers have assured me that they have found evidence of milk on the hedgehog, I do not think that any credence can be given to the statement. The belief probably arises from the extrusion of the contents of the vesiculæ seminales of the buck hedgehog when crushed, kicked, or otherwise injured. The vesiculæ seminales are, when full, extraordinarily large in proportion to the size of the animal, and the milky fluid can easily be mistaken for cow's milk, especially when the hedgehog has rolled itself up for defensive purposes and the face has become smeared with the seminal fluid.

That hedgehogs will eat young birds I have had personal experience, but I doubt if they do much damage to game in this way.

In 1906 and 1907 several albino hedgehogs were found at Goathland, Yorkshire. I attempted to cross an albino doe with a normal buck, but when placed together the latter promptly attacked and killed it. In attempting to breed them in semi-captivity, *i.e.* in a large walled garden, I found that the bucks harried the does a good deal, thus rendering it difficult to secure a litter, and that if the nest was disturbed the mother would frequently eat her young. This proved a real difficulty in the experiments. G. A. Auden.

Birmingham, May 29.

Principles of Picture-hanging.

There is no need for picture-wire (Nature, May 19, p. 362; May 26, p. 395; June 2, p. 438) if the principle is adopted described in the *Times Engineering Supplement* of April, 1919, of the application of Kelvin's Five-Point principle to the picture-hanging.

A rail, say of black enamelled electric conduit tube, is supported along the wall at an appropriate height on bracket-hooks fixed in the wall, and the pictures are hung on the rail by two bent iron hooks fastened on the back of the upper edge of the frame. This gives four points of contact, and the fifth is made by a round-headed screw in the lower edge to set the face at an appropriate cant. One degree of freedom is still left of a motion of the picture sideways into the desired place. A picture is lifted off in a trice and thrown out of the window in case of fire, as of a gallery of portraits in an old mansion; and the pictures can be hung over each other, two and three deep if space is limited, as in the Royal Academy.

The principle is appropriate in a modern physical workshop for the support of apparatus, however heavy, bracketed out from the wall, if a plate is built into a course with a projecting lip. A nail cannot be driven into the glazed-brick wall, but a picture-board can be kept for that purpose and placed where required. The difficulty is avoided of the suspension of apparatus from the roof or ceiling.

The principle seems to have been employed in the Pinacotheca of the ancient Acropolis of Athens. G. Greenhill.

1 Staple Inn, W.C.1, June 6.

Oersted—the Discoverer of Electro-magnetism.[1]

ON July 21, 1820, Hans Christian Oersted, of Copenhagen, announced his great discovery to the world in a circular letter in Latin, "Experimenta circa effectione conflictus electrici in acum magneticam." He describes in detail the apparatus he employed, emphasising the fact that "the galvanic circle must be complete, and not open, which last method was tried in vain some years ago by very celebrated philosophers," gives a list of distinguished men who had witnessed the new effect, and then writes:—

"Let the straight part of this wire"—*i.e.* the wire uniting the two poles of the battery—"be placed horizontally above the magnetic needle, properly suspended and parallel to it; if necessary the uniting wire is bent so as to assume a proper position for the experiment. Things being in this state, the needle will be moved, and the end of it next the negative side of the battery will go westward. If the distance of the uniting wire does not exceed three-quarters of an inch from the needle, the declination of the needle makes an angle of about 45°. If the distance is increased, the angle diminishes proportionally; the declination likewise varies with the power of the battery."[2]

A later communication[3] states that "he discovered by continual experiments during a few days the fundamental law of electro-magnetism, viz. that the magnetical effect of the electric current has a circular motion around it."

The Royal Danish Society of Sciences is celebrating the centenary of Oersted's discovery by the issue of a collected edition of his scientific papers, and the work before us is an essay by Mrs. Kirstine Meyer, forming the first volume of the collection.

H. C. Oersted was born at Rudkjobing in 1777. His father was an apothecary, and Hans Christian and his younger brother, A. C. Oersted, afterwards a distinguished jurist, received their early education from a German wigmaker and his wife, who taught them to read and speak German, but whose knowledge of arithmetic was limited to addition and subtraction; an older schoolfellow taught them multiplication; a friend of the family, division. From their eleventh and tenth years respectively they helped their father in his pharmacy. In 1794 they went to Copenhagen to finish their preparation for their first academic examination, which they passed with honours. As undergraduates they were admitted to Elers College, founded in 1691, which still provides free residence and a small scholarship for needy students. They went through the university course together with distinction, studying mathematics and chemistry, and being greatly interested in philosophy. Kant's teaching was then expounded in Copenhagen by Prof. Riisbrigh, and his lectures markedly influenced them. The lectures on astronomy and physics attracted H. C. Oersted to the study of science; his brother became distinguished for his philosophical writings; but throughout Hans Christian's life we can trace the effect of his early philosophical studies in his work. In 1798 he writes: "I promised you in our last conversation to give you an account in letters of the systematic part of chemistry. . . . I keep my promise with pleasure both for your sake and for that of science, which you know I find so much pleasure in communicating to others." The same year the brothers became members of the editorial staff of a short-lived journal, a philosophical repertorium, the chief object of which was to defend Kant's works.

As regards experimental work, the elder Oersted was limited mainly to the chemical training received in pharmacy where he was employed; the university had no physical equipment. He was helped, however, by Prof. Manthey, professor of chemistry, and owner of the Lion Pharmacy. Manthey was abroad during 1800 and 1801, and Oersted managed his pharmacy. Volta's discovery of the galvanic battery had just been published, and Oersted's earliest experiments were connected with the behaviour of various forms of cells and with the testing of a theory, advanced by Ritter, to account for the decomposition of water by a current: that water *plus* negative electricity produced hydrogen, while water *plus* positive electricity produced oxygen. He measured his currents for these experiments by the aid of a voltameter arranged to collect in a graduated tube the products of the decomposition.

In 1801 Oersted had hopes of a professorship or readership in the university, but he was then looking forward to the prospect of a journey abroad, rendered possible by a grant from "Cappel's Travelling Legacy"; and in a letter to Manthey he says that he would rather resign any post than give up the prospect of the journey. He started in the summer of 1801, and was away until the end of 1803. For a time the world was at peace. Napoleon was First Consul; the war between France and Austria was stayed temporarily by the Peace of Lunéville (February, 1801). The victory of the Nile, 1798, and of Aboukir Bay, 1801, ruined the French plans for an attack on India through Egypt, while access to the Baltic and the defeat of a combination of the Northern Powers against England were secured by Nelson's victory at Copenhagen in April, 1801. The Peace of Amiens followed in March, 1802, and intercourse between men of science of all nations was at once renewed. To us, in 1921, the rapidity with which this took place is somewhat surprising.

Oersted went first to Weimar. At Göttingen he was introduced to Ritter, whose electrical re-

[1] "Scientific Life and Works of H. C. Oersted." By Kirstine Meyer. (From H. C. Oersted: "Scientific Papers," vol. i.) Edited by the Royal Danish Society of Sciences. Pp. clxvi. (Copenhagen: Andr. Fred. Høst and Son, 1920.)

[2] Thomson's "Annals of Philosophy," vol. xvi. (1820), translated from a Latin account sent by the author.

[3] "Edinburgh Encyclopædia," vol. xviii. (1830).

searches impressed him greatly. From Weimar he went to Berlin, where he heard Fichte and Schlegel lecture. At Weimar he had become acquainted with a work by Winterl, "Prolusiones ad Chemiam Decimi Noni," and set himself to make this more widely known, publishing in 1802 a book, "Materialen zu einer Chemie des neunzehnten Jahrhunderts," the object of which was to show the common origin of physical and chemical forces. The book was severely criticised everywhere, and Winterl's chemistry, founded on two mysterious substances, Andronia and Thelycke, has long since been consigned to the oblivion it deserved; but the root-idea, the common origin of most natural forces, lay at the basis of much of Oersted's future work.

From Berlin Oersted went to Paris, visiting Ritter at Weimar on the way, and taking part in some of his experiments. On describing these in Paris, especially the invention of what was probably the first storage battery—a storage column, Ritter called it: a pile of copper plates separated by discs of moist cardboard, which retained a charge for some time after it had been connected to a battery, and was capable itself of giving out a current when its extremities were connected by a wire—Biot asked him to write and advise Ritter to compete for a prize of 3000 livres offered by the First Consul for the most important electrical or galvanic experiment which might compare with the invention of the voltaic pile.

Oersted re-wrote in French the essay Ritter sent in, but the author had stated that his storage column, when placed in a vertical position, became charged through the electrical influence of the earth. Experiments at Paris failed to verify this, and the prize went elsewhere.

Oersted returned to Copenhagen in January, 1804, and was disappointed at not receiving the professorship of physics, which had been vacant for some time. The warden of the university considered him a philosopher rather than a physicist, and it was not until 1806 that he became professor extraordinarius. In 1807 he repeated and extended Chladni's work on vibrating plates, using Lycopodium in place of sand. He noted, but could not explain, the action of the Lycopodium in collecting in the places of maximum vibration; that was left for Faraday.

In 1812 and 1813—the years of Moscow and Leipzig—Oersted again visited Berlin and Paris, and, encouraged by the reception he met with, published his "View of the Chemical Forces of Nature," in which, while expressing his indebtedness to Ritter and Winterl, he dissociates himself in many respects from their theories. He avows his continued belief in the essential unity of natural forces, and, while his views are often vague and unsatisfactory, he proposes that "the experiment should be made whether electricity in one of its most latent forms could act on the magnetic bodies as such." The answer came in 1820. The book was well received everywhere. Thomson writes in the "Annals of Philosophy, 1819," dealing with a later French edition: "The book is highly worthy the perusal of all those British chemists who aim at the improvement and perfection of their science. It is rather surprising that a work of such originality and value should have remained for these four years quite unknown in this country."

In the years which followed, Oersted was busily occupied with routine work. In 1815 he became secretary of the Society of Sciences, and in 1817 professor ordinarius. In this capacity he delivered a series of monthly lectures to advanced students on the progress of science, and it was at one of these in the spring of 1820 that his great discovery was made. His own description of this will be found in the article in the "Edinburgh Encyclopædia" already referred to. After stating that the luminous and heating effect of the electrical current goes out in all directions, "so he thought it possible that the magnetical effect could likewise eradiate"; and after referring to magnetic effects produced by lightning, he continues: "The plan of the first experiment was to make the current of a little galvanic trough apparatus commonly used in his lectures pass through a very thin platina wire which was placed over a compass covered with glass. The preparations for the experiment were made, but, some accident having hindered him from trying it before the lecture, he intended to defer it to another opportunity; yet during the lecture the probability of its success appeared stronger, so that he made the first experiment in the presence of his audience. The magnetical needle, though included in a box, was disturbed; and as the effect was very feeble, and must, before its law was discovered, seem very irregular, the experiment made no strong impression on his audience." Nothing further happened for three months; he delayed his researches until a more convenient time, when a large battery, constructed by his friend Esmark and himself, was available, and then, during a few days in 1820—July 15–20—he made the series of experiments which was announced in the Latin circular letter of July 21 already quoted.

A letter from his pupil Hansteen to Faraday, printed in Bence Jones's "Life of Faraday," gives a fuller account of the original discovery: "At first he had placed the wire at right angles to the direction of the magnet, and found no effect. After the end of the lecture he said: 'Let us now once, as the battery is in activity, try to place the wire parallel to the needle'; as this was made, he was quite struck with perplexity by seeing the needle make a great oscillation almost at right angles with the magnetic meridian. Then he said: 'Let us now invert the direction of the current,' and the needle deviated in the contrary direction. Thus his great detection was made, and it has been said, not without reason, that he tumbled over it by accident. He had not before any more idea than any person that the force should be transversal. But, as Lagrange has said of Newton on a similar occasion: 'Such accidents only meet persons who deserve them.'" Hansteen's remark

would appear to do less than justice to his master, and has proved rather unfortunate, lending colour to the impression that the whole discovery was due to chance. This was far from being the case. Oersted had for years been seeking a connection between electricity and magnetism, and the discovery was the result of his search.

Not the least instructive part of Mrs. Meyer's very interesting book is a series of sheets reproduced in facsimile from notes, mostly in his own handwriting, found among Oersted's papers, which give in detail the experiments with the large battery during July, 1820. Not only did he experiment with a straight wire, but also with one bent into a loop so as to form one complete turn of a circuit, which thus had its north and south face. Oersted saw that such a circuit acted like a magnet. The effect of replacing the magnet by needles made of non-magnetic material was tried, and it was found that they were not disturbed by the current.

The results, announced to all centres of scientific activity, at once produced a great sensation. The paper was published in various journals, and among others in Schweigger's *Journal* for July, 1820, and the same number contains an account of further experiments of importance. Oersted showed in this second communication that the effects "do not seem to depend upon the intensity of the electricity, but solely on its quantity"—in modern words, on the current, and not on the e.m.f. of the supply. Further, he showed, by suspending by a fine torsion wire a small battery and the circuit through which the current passed, that the effect is reciprocal: on bringing a magnet pole up to one face, the circuit is repelled; on bringing the same pole up to the other face, it is attracted.

But while Oersted's experimental work is admirable and his demonstration complete, it is not easy to follow his theoretical ideas. He speaks continually of the "conflict of the electricities" which constitutes a current. The positive and negative electricities flowing in opposite ways round the circuit come into conflict, and it is through their struggle that the various effects are produced. It would almost appear as though he thought that the heat and light radiated from a glowing conductor needed some violence for their origin—violence provided by the struggle between the positive and negative electricities. "He did not consider," he writes himself, "the transmission of electricity through a conductor as a uniform stream, but as a succession of interruptions and re-establishments of equilibrium in such a manner that the electrical powers in the current were not in equilibrium, but in a state of continual conflict." To this conflict he attributes also the magnetic action which originally he anticipated would be radiated outwards from the wire, like heat and light. Experiment proved otherwise; the magnetic action showed itself effective in directions at right angles to the wire, but he did not grasp the idea of a current of electricity flowing in the wire accompanied by a field of magnetic force arranged in circles round the path of the current. In his view, the electricity acted directly on the poles of his magnet, and as the force was due to the electric conflict, this conflict took place, not only in the wire, but also throughout the surrounding space through which the electricity flowed in a series of flat spirals encircling the wire itself. There was a transference of electricity in the direction of the wire; the path, therefore, of the current could not be a circle in a plane normal to the wire, but a spiral giving rise to a component of the motion parallel to the wire. According to his first ideas, though he modified these later, "negative electricity repels the north pole, but does not act on the south pole," while positive electricity acts on the south pole, but not on the north.

In 1828 Oersted writes thus, possibly after he had become aware of Faraday's work: "The electrical stream has a magnetic circulation about its axis. Every act of decomposition due to an electrical current in a given direction is accompanied by a circulation. Through this electrical stream, which, as I have shown elsewhere, is propagated by alternations of positive and negative electricity, there is brought about a series of charges and discharges of particles in the direction of the stream, and a circulation in planes at right angles to it."

The importance of this discovery was recognised everywhere. In Germany, at a somewhat later date, an attempt was made by Gilbert and others to lay stress on its accidental nature. "Was alles Forschen und Bemühen nicht hatte geben wollen das brachte ein Zufall Herrn Professor Orsted in Kopenhagen," he wrote in his *Annalen* in October, 1920, and this view was accepted by many of his contemporaries; but elsewhere Oersted received full and generous credit. The French physicists, led by Arago and Ampère, took up eagerly the investigation of the new phenomena, and in a few months Ampère established the laws of the mechanical action between electric currents. "The whole theory and experiment," writes Maxwell, "seems as if it had leaped full grown and full armed from the brain of the 'Newton of Electricity.' It is perfect in form and unassailable in accuracy, and it is summed up in a formula from which all the phenomena may be deduced, and which must always remain the cardinal formula of electro-dynamics." Ampère's brilliant work somewhat overshadowed Oersted's merit, which, however, the French investigators fully recognised.

In England Sir Humphry Davy was the first to repeat the experiments, using for the work "the great battery of the London Institution, consisting of 2000 plates of zinc and copper"; he showed at an early date that the arc between two charcoal electrodes was altered in shape when a magnet was brought near. In April, 1821, Faraday wrote an historical survey of the growth of the subject up to date, stating that Oersted's results "comprise a very large part of the facts that are yet known relating to the subject," and pointing out that his constancy in the pursuit of his

inquiries respecting the identity of chemical, electrical, and magnetic forces "was well rewarded in the winter of 1819 by the discovery of a fact of which not a single person besides himself had the slightest suspicion, but which when once known instantly drew the attention of all those who were at all able to appreciate its importance and value."

From the autumn of 1822 to the summer of 1823 Oersted was in Germany, France, and England. He is less enthusiastic than in the past about the German men of science whom he met. "Schweigger at Halle has brains, but is a reed shaken with the wind. His experiments are not of much importance. Kastner at Erlangen writes thick volumes compiled with much toil but without all judgment. Yelin at Munich makes indifferent experiments and lies much. But I have found much that was instructive with Fraunhofer at Munich, so that I have been able to occupy myself with benefit there for about a fortnight."

To the Frenchmen he is more kindly. "My stay here grows more and more interesting to me every day. The acquaintances I have made grow every day more cordial and intimate," he writes to his wife from Paris in February, 1823. He saw Biot, Fresnel, Pouillet, Ampère, Arago, Fourier, Dulong, and many others: such was the brilliant list of physicists then at work in Paris. With Ampère he had many discussions as to their rival theories; at one time he thought he had disproved the existence of the molecular currents which in Ampère's view constitute a magnet. Mrs. Meyer quotes from another letter an amusing account of a three hours' discussion which took place after a dinner given by Ampère. Among the guests were two of the host's pupils, and of them Oersted writes: "Even Ampère's two disciples declared that my theory was able to explain all his phenomena. They declare that so will Ampère's, and as his theory is nothing but the reverse of mine, he having removed the circuits of forces discovered by me from the conductor to the magnet, it will no doubt be difficult to find an entirely decisive objection to his theory."

The experiments which Ampère arranged for his benefit were not successful. "On the 10th I was at Ampère's by appointment to see his experiments. He had invited not a few. . . . He had three considerable galvanic apparatus ready; his instruments for showing his experiments are very complex; but what happened? Hardly any of his experiments succeeded. He is dreadfully confused, and is equally unskilful as an experimenter and as a debater." Somehow this is hard to believe; some at least of the confusion existed, we may suspect, in the mind of the narrator. Ampère's own descriptions of his work are models of clearness; his formula remains, as has been said above, "the cardinal formula of electrodynamics."

Oersted lived for some thirty years after the discovery of 1820, engaged almost to the last in physical work. During part of the time he was greatly interested in measurements of the compressibility of liquids. Details of some of these are given in a letter to Brewster dated December 30, 1826. He was one of the first to realise the necessity of allowing for the expansion of the vessel containing the liquid, and a piezometer which he described in the Proceedings of the Danish Society of Sciences for 1821 has been frequently employed for measurements of the kind, though Oersted was mistaken in thinking that it avoided all the difficulties arising from the expansion of the containing vessel.

Under date 1845 we have the following suggestion for a moving coil galvanometer: "A metal wire bent as a multiplier and able to revolve easily round two points is placed opposite the poles of a strong magnet in such a way that it will be deflected as soon as it is traversed by electricity."

In 1848 Denmark was at war, and in a letter of that date Oersted alludes to the fact that thirty years earlier he had experimented on the use of electricity for firing mines, and makes the suggestion of "burying in a road to be taken by an attacking enemy, under a comparatively thin layer of earth, small reservoirs filled with gunpowder and earth or small fragments of stones which could be fired by a communicating wire on a given signal and that in a shorter time than one second after the signal."

More will be found in Mrs. Meyer's excellent volume about the activities of a remarkable man; she has done her work admirably, and we are indebted to her for her labours in producing this most interesting work. The book, which is printed in English, has been published in Copenhagen under the editorship of the Royal Danish Society of Sciences, and is in every way a worthy memorial of perhaps the most distinguished member of that society.

R. T. G.

Native Life in the Loyalty Islands and Southern Nigeria.[1]

By HENRY BALFOUR.

(1) MRS. HADFIELD'S book on the Loyalty Islands is the outcome of a long residence in this group, in connection with the work of the London Missionary Society. The greater part of the time was spent on Lifu Island, but eight years were spent on the smaller island of Uvea. The account which she gives of the natives is unpretentious and straightforward, written in an easy and attractive style and with a vein of humour. She reveals her sympathy with the natives, with whom she became on excellent terms, and much

[1] (1) "Among the Natives of the Loyalty Group." By E. Hadfield. Pp. xix+316 (London: Macmillan and Co., Ltd., 1920.) 12s. 6d. net.
(2) "Among the Ibos of Nigeria: An Account of the Curious and Interesting Habits, Customs, and Beliefs of a Little Known African People by One who has for Many Years Lived amongst Them on Close and Intimate Terms." By G. T. Basden. Pp. 315. (London: Seeley, Service, and Co., Ltd., 1921.) 25s. net.

FIG. 1.—Type of Uvean native, Loyalty Islands. From "Among the Natives of the Loyalty Group."

of the information acquired regarding their habits, customs, and ideas was the reward of having gained the confidence of the islanders. Although but some sixty miles separate the Loyalty group from New Caledonia, the natives of the former, with their cheery disposition and laughter-loving habit, differ markedly from the dour, sullen natives of the latter. The tradition that Uvea was peopled partly by immigrants from the Polynesian Wallis Island (also called Uvea), lying about 1000 miles away, is borne out by the fact that Uvea boasts of two languages, the original "Iaian" and a distinct and apparently intrusive language spoken in the north and south of the island. This Polynesian intrusion explains, perhaps, the temperamental difference which is noticed between the Loyalty Islanders and the more strictly Melanesian New Caledonians, and also accounts for certain customs and appliances which exhibit Polynesian affinities.

The account given by Mrs. Hadfield of the mentality, daily life, useful and æsthetic arts, and also of the customs, social ethics, and legends of the Loyalty Islanders, is very concise and full of interest. One cannot but recognise how rapidly the old indigenous culture is disappearing. The author dwells upon their many good qualities, and endeavours to account for those characteristics which civilisation deems undesirable and bad. Allowances must be made for the native point of view and for the environment, though the former is always difficult of diagnosis. Even in war a system of sportsmanlike etiquette prevailed, and certain unwritten laws were studiously observed. Due notice was given of an impending "state of war," and operations were not commenced until after the expiry of a period of several days. The heads and noses of children were modified by pressure in order to induce the orthodox, fashionable shape, a practice which is of much interest owing to its wide dispersal over the world, but is disconcerting to the ethnological craniometrist.

The natives exhibit skill and boldness in surgery, though their methods are necessarily of the crudest. Trepanation was freely resorted to, and with success; fractures were dexterously reduced. Hygienic principles are practically non-existent, and the spread of infectious diseases is rapid. The intro-

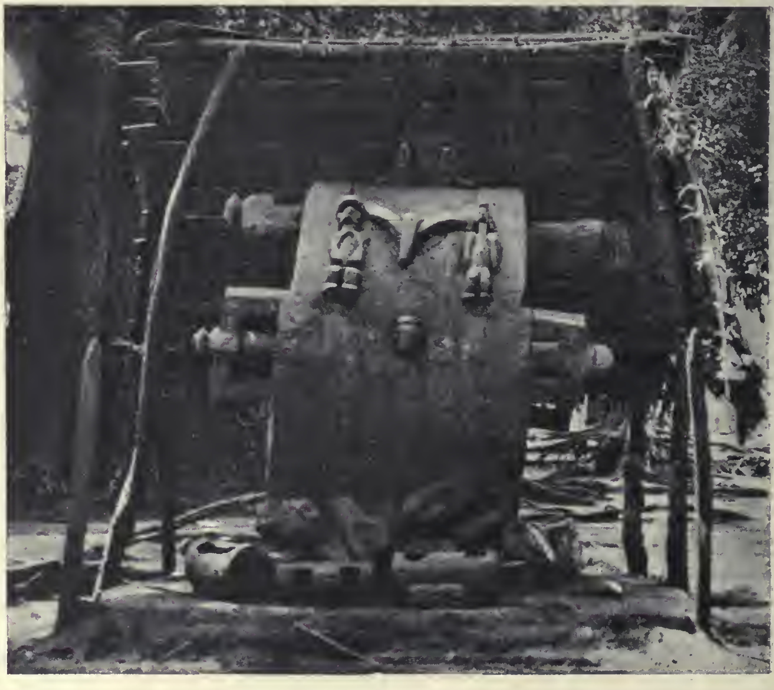

FIG. 2.—The wonderful wooden gong of Umu-nze, the maker of which was murdered lest he should make an even finer one for another town. From "Among the Ibos of Nigeria."

duction of foreign diseases has had a disastrous effect, accentuated by the imported vices, which are usually more attractive and more easily assimilated than are the white man's virtues. Fear of death does not appear to weigh heavily upon the natives. A number of native legends is given at the end of the volume, affording useful material for comparative study.

It may seem ungrateful to express the wish that Mrs. Hadfield's descriptions of industries, appliances, and habits might have been more detailed, since the production of a complete textbook was not her intention. In asking for more, one does so in full recognition of the praiseworthy and useful work performed by the author in giving us this very readable and well-illustrated book, which deserves fuller notice than can here be given.

(2) Another product of many years of missionary intercourse with natives, involving close personal contact, is the Rev. G. T. Basden's volume dealing with the Ibos of Southern Nigeria. The author has aimed at giving a fairly detailed, though popularly written, account of these interesting natives, and has succeeded in producing an instructive and attractive volume. He sounds a note of caution which may well be taken to heart by globe-trotters and stay-at-home amateurs who, with little or no experience, write books about native ideas and beliefs. He writes: "The longer one lives amongst West African natives, the more one is convinced that it is a practical impossibility for the European to comprehend fully the subtleties of the native character. Some white men claim to have done this, but my experience leads me to think that the claim can rarely, if ever, be substantiated with definite assurance."

FIG. 3.—Hair-dressing as a work of art. From "Among the Ibos of Nigeria."

This is an honest admission on the part of one who has lived long enough among the natives to realise the difficulties involved in the diagnosis of their mentality, and to recognise the fundamental difference between their "philosophy" and ours. The Ibo people, who form nearly one-half the population of Southern Nigeria, occupy the country lying mainly between the Niger and Cross rivers, a huge tract extending from the coast to 7° N. lat. There is a westerly extension across the Niger. The Ibos are not homogeneous, important variations occurring in the extensive area occupied. The environment varies considerably, from the low-lying swamps of the Delta to the higher land around Onitsha.

The book is a timely one, since the indigenous customs are very rapidly undergoing changes, though in 1900, when Mr. Basden arrived there, primitive conditions still largely persisted. The general life of the Ibos is well presented. A man's greatest desire in life is to advance in social status, and many crimes are committed in order to promote this advancement. Theft (to obtain the necessary funds), murder, and head-taking (as a sign of prowess) are very usually the outcome of this craving for higher titles. Cannibalism has been rampant, human flesh being regarded as a valuable food product. Polygamy is favoured equally by both sexes, and will be suppressed only with great difficulty. The first wife takes prece-

dence of all the others, and is regarded as the legal wife, *anasi*, who is priestess of the household gods. Belief in the survival of the soul prevails, and adequate burial of the dead is a matter of great concern. A first, necessarily hurried burial takes place soon after death, but a second more elaborate and very costly "burial" by proxy is performed later, with the view of keeping the spirit of the deceased in contentment. Failing this propitiation, the spirit may become restless and malignant. Reincarnation is believed in. Children are well treated and thrive, and although their treatment is often very drastic and appears cruel, the parents evince great fondness for them. Twins, however, are held in abhorrence. In this respect the Ibos differ from the neighbouring Ekoi, who welcome twins. Boys are initiated into the mysteries of the Ayakka secret society at the age of ten.

The secret societies are dealt with by the author in detail, and the religion and superstitions are well, if briefly, described. The chief deity is Abwala, and at her shrine oracles are sought and "trials" are conducted. The priests, in consequence, exercise a great controlling influence, as is so often the case in Africa. The arts and crafts and the trading methods are interestingly dealt with, and one feels that the author has command of more information than could be published in a single volume. The illustrations are excellent and fairly numerous. One wonders why the household god called in the text *Ikenga* (p. 219) is designated *Skenga* on the plate (p. 120), and why the illustrations are sometimes inserted far from the text to which they refer. It would have been advantageous if all native names had been printed in italics. Such minor blemishes, however, do not materially lessen our appreciation of this very useful and instructive volume. Both the author and his readers may be congratulated.

Obituary.

Peter Donald Malloch.

Ardent naturalists in humble ranks of life during last century, such as Edwards, of Banff, and Robert Walker, of St. Andrews, in zoology, and Sergeant Sim, of Perth, in botany, have not been rare in Scotland, but few showed more acute penetration, combined with artistic skill and fitness for administration, than Peter Donald Malloch, the premier angler and skilful taxidermist, as well as the originator and able administrator of the Tay Salmon Fisheries Co.

A native of the neighbourhood, Malloch spent most of his life in the Fair City, taking the foremost place, after the death of Mr. Lamb, as a taxidermist (many examples of his skill being now in the Perth Museum), then well known for his remarkable success as a practical angler, and, lastly, as manager of the salmon syndicate just mentioned. It was in Perthshire that the artificial hatching of the salmon at Stormontfield ponds first attracted the attention of men of science in the fifties and early sixties of last century, and the work of Robert Buist, Wm. Brown, and John Dickson made it widely known. Malloch, however, following these, and in the unique position he held on the finest salmon-river in the country, one which carries the largest body of fresh water to the sea, was able to clear up certain ambiguities, and though he had no training in science he grasped the information derived from an investigation of the scales of the salmon, sea-trout, and other fishes, and worked out their life-history with great accuracy and acuteness. In 1910, indeed, he collected all his information in an interesting work entitled "Life-history and Habits of the Salmon, Sea-trout, and other Fresh-water Fish," a work illustrated by as many as 239 exquisite life-like photographs—mainly by himself.

Malloch's observations on the various classes of salmon ascending the rivers, and a comparison of their movements with those of the sea-trout (the latter feeding in fresh water, whilst the salmon does not), are of great interest and value in this complex subject. He believed that almost all salmon in the sea make for the rivers where they were born. He had some hesitation in accepting the view that some of the parr become smolts at the end of their first year, but old "Peter of the Pools" at Stormontfield would have strengthened the case by demonstrating that many of the year-old parr reared there grew apace, assumed the silvery coat, passed down the rivulet to the pen near the river, and would even leap over its edge in their eagerness to migrate seaward.

Malloch's efficient marking of the smolts with silver wire gave him much information as to the rate of growth of the salmon, irregularity in spawning, and other points. His wide experience of the Tay and other rivers and of numerous lochs enabled him to corroborate Dr. Gunther's opinion as to bull-trout, and so with his remarks about yellow fins and whitling, the young of the sea-trout. Further, the acuteness of his observations is shown by his finding a new char (*Savelinus Mallochi*, Tate Regan) in a lake in Sutherland. That he was able to accomplish so much in the midst of strenuous commercial fisheries work, comprehending the Tay from Stanley to the sea, the surveying of rivers and lochs, and the letting and sale of highland estates, shows that his capacity was of no ordinary kind. Perth has always been the centre from which has emanated much of the life-history of the salmon, and Malloch enhanced and extended that reputation. He died toward the end of May at the age of sixty-eight years.

W. C. M.

We much regret to see the announcement of the death, from heart failure, on June 5, of Dr. A. M. Kellas, of the Mount Everest Expedition.

Notes.

THE Albert medal of the Royal Society of Arts for 1921 has been awarded to Prof. J. A. Fleming in recognition of his many valuable contributions to electrical science and its applications, and especially of his original invention of the thermionic valve, now so largely employed in wireless telegraphy and for other purposes.

NOTICE is given by the University of London that the advanced lectures by Prof. A. D. Waller and Mr. J. C. Waller on "Experimental Studies in Vegetable Physiology and Vegetable Electricity," announced for delivery on June 15, 22, 29, and July 6, cannot now be given.

THE Importation of Plumage (Prohibition) Bill, as amended in Standing Committee, was read a third time in the House of Commons on June 10.

THE grant of 5000*l*. a year promised by the Government for five years to the Empire Cotton Growing Corporation (on condition that 90 per cent. of the cotton industry should agree to contribute by means of a voluntary levy on every bale of cotton imported into England, which agreement has now been obtained) is to be replaced by the grant of a capital sum of 1,000,000*l*. to the corporation. This announcement was made by Mr. Winston Churchill in Manchester on June 7. The capital sum in question is about a quarter of the total profits made by the British and Egyptian Governments from their joint control of the cotton supply during the war. These profits are being shared equally between the two Governments, and half the British Government's share is to be utilised for the promotion of Empire cotton.

THE Minister of Agriculture has announced the gift to the nation by Lord Lee of a large estate of 1300 acres, being part of the Chequers estate, of which 700 acres is farmland and the remainder woodland. The Ministry proposes that the main farm should be conducted as an example of the stock-rearing farm, showing how land of that character could be improved so as to produce the maximum output of livestock consistent with sound commercial agriculture. It is considered that the farm could be made a valuable demonstration of the growth and value of improved varieties of cereals and fodder crops and of the amelioration of grassland to be utilised for the intensive breeding and rearing of livestock, without departing from the prime economic purpose of any farm which is intended to guide the practice of the working farmer. At the same time it is hoped to come to some arrangement with the Bucks County Council, under which the Dropshort Farm could be utilised for more definitely educational purposes as the holding attached to a farm institute. It is a hopeful augury, and one not without significance, that future Prime Ministers should be able to see at their doors an example of agricultural education in being. Lord Lee's munificent donation adds to the debt of gratitude which the nation already owes him, and gives the agricultural authorities an opportunity of carrying out work which has long been needed, and which they have long desired to do.

THE fifth International Rubber Exhibition was opened on June 3 by Sir Owen Philipps, M.P., at the Royal Agricultural Hall, Islington. Notable exhibits of rubber and other tropical produce were shown by commercial firms and by British overseas and foreign Governments, the colonial exhibits of the latter being particularly good. From the scientific point of view the display illustrating the mycological work which is being carried out under the auspices of the Rubber Growers' Association, and the fine exhibit of the Java rubber research stations, call for special mention. The most important feature of the exhibit of the Rubber Growers' Association was the effectively arranged demonstration of the discovery by the Botany Department of the Imperial College of Science and Technology that, in all probability, "brown bast" (the most serious disease of *Hevea brasiliensis*) is essentially a question of phloem necrosis. Sanderson and Sutcliffe (the latter a former student of the college), in their investigation of the anatomy of burr-formation, which is the principal external symptom of brown bast, had shown that the burrs result from the inclusion of areas of diseased laticiferous tissue in stone-cell "pockets" formed by the activities of wound cambiums. The recent work at the Imperial College, however, focusses attention upon the probability that the disease has its origin in an affection of the sieve-tubes (phloem), the symptoms described by Sanderson and Sutcliffe being a secondary development. The important information now available should be a step forward to the discovery of the causative factors of this baffling disease. Another series of preparations demonstrated the action of certain fungi (Diplodia, Nectria, and Fusarium) as wound parasites; cultures of fungi obtained from Hevea trunks were also shown. A further exhibition of the department comprised a series of seed-germination experiments, which showed that rubber seed which had failed to germinate was already infected with Diplodia, a fungus known to cause a disease of Hevea seedlings. Reference must also be made to the interesting exhibit illustrating the course of instruction in rubber technology which is being conducted at the Northern Polytechnic Institute, Holloway.

THE British Cast-Iron Research Association has been approved by the Department of Scientific and Industrial Research as complying with the conditions laid down in the Government scheme for the encouragement of industrial research. The secretary of the association is Mr. Thomas Vickers, Central House, New Street, Birmingham.

AT the anniversary meeting of the Linnean Society of London, held on May 24 last, the following officers were elected:—*President:* Dr. A. Smith Woodward. *Treasurer:* Mr. H. W. Monckton. *Secretaries:* Dr. B. Daydon Jackson, Prof. E. S. Goodrich, and Dr.

A. B. Rendle. *Members of Council:* Prof. Margaret Benson, Prof. V. H. Blackman, Mr. E. T. Browne, Mr. H. Bury, Mr. S. Edwards, Prof. E. S. Goodrich, Dame Helen Gwynne-Vaughan, Sir Sidney F. Harmer, Dr. B. Daydon Jackson, Mr. C. C. Lacaita, Mr. G. W. E. Loder, Mr. H. W. Monckton, Mr. R. I. Pocock, Capt. J. Ramsbottom, Dr. A. B. Rendle, Lord Rothschild, Dr. E. J. Salisbury, Mr. C. E. Salmon, Mr. Thomas A. Sprague, and Dr. A. Smith Woodward.

The nineteenth annual meeting of the South African Association for the Advancement of Science will be held at Durban on July 11–16, under the presidency of Prof. J. E. Duerden, of Rhodes University College, Graham's Town. As in previous years, the association will meet in six sections, the presidents of which are as follows:—Section A (Astronomy, Mathematics, Physics, Engineering, etc.), Dr. J. Lunt, of the Royal Observatory, Cape of Good Hope; Section B (Chemistry, Geology, Geography, etc.), Dr. J. Moir, Chemist to the Mines Department, Johannesburg; Section C (Botany, Forestry, Agriculture, etc.), Prof. J. W. Bews, of Natal University College, Maritzburg; Section D (Zoology, Physiology, Hygiene, etc.), Prof. H. B. Fantham, of University College, Johannesburg; Section E (Anthropology, Philology, etc.), Dr. C. T. Loram, of the Natal Education Department; and Section F (Education, Sociology, History, etc.), Prof. W. A. Macfadyen, of Transvaal University College, Pretoria. The general secretaries of the association are Dr. C. F. Juritz, Department of Agriculture, Cape Town, and Mr. H. E. Wood, Union Observatory, Johannesburg. Capt. H. A. G. Jeffreys, P.O. Box 6894, Johannesburg, is acting as assistant general secretary. It is announced that the 1922 meeting will be held at Lorenço Marques under the presidency of Dr. A. W. Rogers, Director of the Geological Survey of the Union of South Africa.

Evidence of considerable interest in relation to the character and distribution of Iron-age culture in the Balkan Peninsula has been obtained by Mr. Stanley Casson in the course of a journey through parts of Macedonia. This journey was undertaken under the auspices of a research committee, of which Sir William Ridgeway is chairman, of the British Association, appointed to excavate early sites in Macedonia. Starting from Dedeagatch, the port at the mouth of the Maritza River, Mr. Casson worked westward through Enos, Drama, and Cavala. He also visited Vodena and Ostrovo. Excavations were undertaken at Chauchitsa, which during the war was one of the railheads on the British Doiran-Vardar front. The "finds" included bronze ornaments, pottery, some gold, and a number of iron knives. The results of Mr. Casson's investigations of this area, of which little is known archæologically, will be described in full in the Anthropological Section at the Edinburgh meeting of the British Association in September next.

The lectureship established to commemorate the work of Mr. Moncure Conway was held this year by Dr. A. C. Haddon, who selected as his subject "The Practical Value of Ethnology." After a preliminary survey of the relations of sociology and history to anthropology, Dr. Haddon proceeded to discuss the relations of peoples of the higher to those of the lower culture under the heads of Conduct, Control, and Care. In regard to "conduct," he urges that dealings between groups, as well as those between individuals, should be conducted with the greatest possible consideration for their several sentiments and prejudices. Under the head "control" he considers the value of the knowledge of anthropology to the statesman and administrator. By "care" he means the efforts which can be made to check the evil results which arise from the contact of the higher with the lower civilisation in the prevention of epidemics, the problem of the dying-out of native races, the avoidance of meddlesome interference, and so on. Problems of this kind are familiar to all ethnologists, but Dr. Haddon's exposition of the subject is admirable, and it is illustrated by an interesting selection of facts drawn from his wide knowledge of anthropological literature and practical experience as a traveller. The lecture deserves the careful attention which it is sure to receive from all who are interested in the advance of our common humanity.

An interesting phase of the social life of Roman society in the Ciceronian age is described by Messrs. A. W. Van Buren and R. M. Kennedy in a paper contributed to the *Journal of Roman Studies* (vol. ix., part 1) on Varro's aviary at Casinum. Marcus Terentius Varro, author of the famous work on agriculture, "De Re Rustica," gives a long account of this building, which is here quoted and translated. It contained fish-ponds and duck-houses, the latter enclosed by fine gut nettings, and spaces shut off by nets for songsters, such as nightingales and blackbirds, supplied with water by means of a small channel, while food was thrown to them under the net. Several of the elements which enter into the arrangement of Varro's aviary recur in a contemporary Pompeian painting from the villa of Julia Felix.

The American Museum of Natural History has set a good example in founding a new journal for the publication of preliminary announcements and the description of new species. It is to be known as the *American Museum Novitates.* No. 1, which has just reached us, is devoted to an extremely interesting and stimulating survey of the evolution, phylogeny, and classification of the Proboscidea by Prof. H. F. Osborn, who within the compass of a few pages has provided food for thought and much debate for some time to come. All interested in palæontology will note with satisfaction that the author frankly rejects his earlier views in regard to Mœritherium, and subscribes to the opinion originally started by Dr. C. W. Andrews, of the British Museum, that it is to be regarded as an indubitable proboscidean. But they will probably fail to grasp the precise meaning of the author's contention that "the enlargement of the second upper and lower incisor teeth . . . presents a firm ground of affinity with a still unknown primitive Lower Eocene proboscidean-stem form. There the resemblance ends." We venture to think that when Prof. Osborn's studies of this remarkable fossil are

completed he will still further modify his conception as to the ancestral position of this animal, when the system of proboscidean classification proposed in this essay will be materially changed.

The annual report of the Smithsonian Institution for the year ending June, 1918, contains as usual, in addition to the secretary's report, a valuable general appendix consisting of twenty-seven papers illustrating the more important developments in physical and biological science, among them being translations of contributions by foreign men of science. In one of these, "On the Law of Irreversible Evolution," Dr. Branislav Petronievics sets forth an exposition based on Lewis Dollo's own works of the principle that "an organism cannot return even in part to a previous condition already passed through in the series of its ancestors." Another translation is "The Fundamental Factor of Insect Evolution," by S. S. Chetverikov—a paper which was first published in Russian. The opposite direction of the paths of evolution of vertebrates and invertebrates is accounted for by assuming that the chitinous skeleton of insects enabled them to diminish continuously the size of the body and so to obtain for themselves an independent place among terrestrial animals while increasing in endless variations of form. The third translation included in the volume is "The Psychic Life of Insects," by E. L. Bouvier—a paper in which the author attempts to show that the predominance of instinctive activity among insects is due to the multiplicity of appendages, and that, in consequence, their main psychical task consists in engraving on their memory and in repeating instinctively the acts to which these organs are adaptable.

Excellent photographs of the skull, mandible, cervical vertebræ, and fore and hind feet of the giant extinct marsupial Nototherium, found last year at Smithton, Tasmania, are published by Messrs. H. H. Scott and Clive E. Lord in their account of the specimen, which is now in the Tasmanian Museum, Hobart (Proc. Roy. Soc. Tasmania, 1920). Nototherium seems to have borne a dermal horn on the nose, and may have played the part of a rhinoceros in the marsupial fauna of the Australian region. Its feet, however, are peculiar, and closely resemble those already known in Diprotodon. Messrs. Scott and Lord discuss these features specially, but their use of English words and their style of composition are so unfamiliar that it is difficult to grasp their meaning.

In the *Brooklyn Museum Quarterly* for January, Mr. R. C. Murphy, the curator of natural history, continues his account of "The Sea-coast and Islands of Peru," dealing here with the Chincha Islands, and including a narrative by Dr. F. A. Lucas, who spent three months there on a guano ship in 1869.

Part 2 of the Quarterly Journal of the Geological Society for 1920 (vol. lxxvi.) is occupied by palæontological papers. Mrs. Eleanor Mary Reid describes two pre-Glacial floras from beneath the Boulder Clay of Castle Eden, on the Durham coast. By a careful comparison with French and Dutch deposits, the author assigns one to the Middle and the other to the Upper Pliocene. She follows with "A Comparative Review of Pliocene Floras based on the Study of Fossil Seeds," the inspiration for which came from the work carried on by herself and her husband, the late Mr. Clement Reid, between 1904 and 1915. The general conclusion is that at the opening of Pliocene times a flora existed in western Europe which was closely allied to the living floras of far-eastern Asia and of North America; but this gradually disappeared, until, in the Upper Pliocene bed of Cromer, it was represented by only 0·74 per cent. of the plants examined. The succession of the floras is Pont de Gail (Cantal), which is practically Miocene; Reuverian (from Reuver, north-east of Roermond, Holland); Castle Eden (Durham); Teglian (from Tegelen, on the Meuse, south of Venlo, and north-east of Reuver, in Holland); and Cromerian (Norfolk). In the same issue of the journal Dr. F. J. North publishes a detailed study of the brachiopod genera Syringothyris and Spiriferina, which he finds to be unrelated. He establishes a new genus, Tylothyris, for McCoy's *Spirifera laminosa*.

In a paper on "The Nature of Palæozoic Crustal Instability in Eastern North America" (*Amer. Journ. Sci.*, vol. l., p. 410, 1920) Dr. C. Schuchert connects considerable epochs of diastrophism with the close of geological periods. He urges that the latter are determined by changes of fauna, and the "quickened evolution of the earth's plants and animals" is a response to altered conditions of the surface. Hence the unconformities after epochs of disturbance, such as the "Nevadian" epoch of mountain-building at the close of the Jurassic period, which affected the whole region from Lower California to Alaska, may fairly be taken as stratigraphical boundaries. It may be remembered that similar reasoning was put forward by Prof. T. C. Chamberlin in the *Journal of Geology* for 1909. Dr. Schuchert hesitates, however, at closing the Mesozoic era in America with the top of the Jurassic, and it is obvious that a review of the contemporary faunas throughout the world is necessary for a reasonable delimitation of the groups and systems.

The utilisation of the artesian water resources of Western Australia is making progress. An article on the subject by Mr. A. G. Maitland appears in the Mining Handbook (Geological Survey Memoir, No. 1) issued by the Minister of Mines. Mr. Maitland maps the location of five artesian basins in Western Australia which vary much in size and importance. Most significant, as bearing on the pastoral possibilities of the State, is the so-called desert basin in the north-west covering the area usually known as the great sandy desert. The disposition of the rocks gives ideal artesian conditions, the water being, in the main, derived from the rainfall of the Kimberley district. The six or seven bores which have been sunk in this desert area have been sufficiently successful to give high promise for further operations. North of the Great Australian Bight artesian conditions seem to be favourable in the Eucla basin, but more investigation is required. In five out of thirteen bores the water rose freely.

At the request of the American Geographical Society, Sir John Scott Keltie has prepared a short report on "The Position of Geography in British Universities" (Research Series No. 4). Sir John Keltie, in addition to giving some details for each university, reviews briefly the history of geographical education in Great Britain, and shows that considerable progress has been made in this country since his well-known report on the subject in 1885. At that date geography was practically unrecognised in British universities, while at present there are only two universities in England and one in Scotland in which there is no separate department in geography. Despite this progress, much remains to be done. In many universities the departments are understaffed, and the subject has a hard, and not always successful, fight to find its due place in the curricula. There is diversity of opinion regarding the scope of the subject and methods of treatment. In a few universities the subject is in both the faculties of arts and sciences, but in some it is only in arts. The addition of degrees in commerce has resulted in increased demand for geography, but on somewhat restricted lines, which cannot do justice to the subject. Sir John Keltie thinks there is need for geography to limit the field of its operations and to avoid the embarrassment of overcrowding.

The Ministry of Finance, Egypt, has recently issued a Blue Book embodying the programme and policy of the Egyptian Government in regard to the development of the oil resources of that country. The chief point of interest in the publication is the defence put forward by the Under-Secretary of State for Finance, Mr. E. M. Dowson (under whose name the book appears), in support of the policy of State boring for oil determined upon in 1919. In other words, the justification of the expenditure of public money on petroleum mining in Egypt is pleaded in view of the growing scarcity and enhanced price of oil fuel as a measure of internal economy and as an attempt to further the scientific development of the oil resources of the country. State enterprise in such a risky business as oil-finding is usually to be deplored, but there are certain factors to be recognised in the political elements here engendered which not only warrant some co-ordinated efforts to deal with a difficult situation, but also make it essential that some authoritative scheme should be adopted to stabilise the oil industry of the country. The present policy includes the reservation of certain likely petroliferous areas for the Government as a result of a preliminary geological survey; such areas include Abu Durba, the west coast of Sinai, several isolated areas in northern Sinai, two smaller areas on the west coast of the Gulf of Suez at Ras Dib and Zeit Bay, and a larger area at Abu Sharr adjoining the better-known Hurghada field. The location of a commercially productive field in any one of these areas would justify, at any rate from a Government point of view, all the expenditure entailed in obtaining, transporting, refining, and distributing the oil. Failure, on the other hand, will be severely criticised, not only at home in Egypt, but also abroad. The scientific results accruing from the borings, however, must have considerable value in the task of assessing the oil potentialities of the country, but ultimately it will be for the Egyptian people to pass judgment on a policy the merits or demerits of which as yet remain to be substantiated.

In the *Radio Review* for May Mr. T. L. Eckersley concludes his inquiry as to whether the errors in the apparent bearings of radio stations from which messages are received at night can, in whole or in part, be explained by the existence in the atmosphere of an outer conducting layer which he calls "the Heaviside layer," at the under-surface of which the electric waves are reflected. He thinks that the existence at night of such a reflected wave-train must now be taken as proved, and proposes to determine by measurement whether there is any component of the electric force horizontal and perpendicular to the plane of propagation. If this proves to be the case, the surface of the conducting layer at which reflection takes place cannot be taken as horizontal. Mr. Eckersley is disposed to think that in many cases the reflection is of this kind. The influence of the layer in the daytime is less marked, as it extends down to the ground and produces absorption of the waves propagated through it. In the night it has a more or less sharp under-boundary, at which reflection can take place and the waves are confined almost entirely to the layer of air underneath.

The February issue of *Radium* contains a report of the Leonard prize for research recently instituted by the American Röntgen Ray Society. The prize, which commemorates the name of Dr. C. Lester Leonard, a victim to X-rays, is for the best piece of original research in the field of X-rays, radium, or radio-activity, and is of the value of 1000 dollars. This competitive award is open to anyone living in the western hemisphere. In the same issue notice is given of a correspondence course in the physics of radio-activity suitable for the needs of biologists and surgeons as well as of physicists. The course is being arranged by Dr. N. E. Dorsey, of Washington, consultant to the National Bureau of Standards.

Dr. C. E. K. Mees, director of the research laboratory of the Eastman Kodak Co., Rochester, N.Y., contributes to the Journal of the Franklin Institute of May 21 an excellent summary of the present knowledge of the structure and many of the properties of photographic films before and after use. Concerning the unexposed emulsion, the silver bromide particles are crystals belonging to the regular system. They show evidence of strain, perhaps because there is absorbed in them some other substance, such as silver iodide, soluble bromide, or gelatine. The sizes of the crystals are determined during the formation of the silver salt when making the emulsion, and their diameters range from ultra-microscopic particles below $0 \cdot 1\mu$ to occasional grains up to 10μ. The curve relating the sizes of grains to the number of each size present is probably closely related to the "characteristic curve" of the emulsion. Grains of the same size may vary in sensitiveness, and the sensitiveness of grains of different sizes in the same emulsion may vary from group to group. A geometric relation between the sensitiveness of grains of different sizes is

sufficient to account for the properties of emulsions prepared in different ways. The author treats of the character of the developed image, and distinguishes between the graininess due to the individual particles of silver, the aggregations of these particles, and the agglomeration of these primary aggregations. The sharpness of the image is discussed, curves showing the quantitative values of these properties are given, and the methods by which these properties have been investigated are described.

YEAR BOOK No. 19 of the Carnegie Institution of Washington contains the nineteenth annual administrative report of the president, together with the reports on investigations and projects submitted by the various departments of the institution. Two sections of the presidential address, the financial records and the list of the institution's publications for the year, disclose some interesting facts. The total income available for the year ending October 31, 1920, was roughly 388,000*l.*, and of this sum about 278,000*l.* was allotted to the various departments. The Department of Terrestrial Magnetism received the biggest grant, some 51,000*l.*, while Mount Wilson Observatory received 45,000*l.*, and the Geophysical Laboratory the notable sum of 31,000*l.* Another large item in the expenditure was the production of the well-known publications of the Carnegie Institution, of which twenty-two were issued and a further eight authorised for publication during the course of the year; this work absorbed some 17,000*l.* The bulk of the Year Book is devoted to reports showing the progress of investigations carried on during the year; reports of directors of departments are given first, followed by reports of recipients of grants for other investigations, the latter being arranged according to subject.

THE latest catalogue (No. 415) of second-hand books offered for sale by Mr. F. Edwards, 83 High Street, Marylebone, W.1, deals with works relating to British and foreign birds, and natural history voyages and travels. It contains nearly 400 items, many formerly the property of the late Dr. F. du Cane Godman, and several choice and scarce works. It will appeal to ornithologists. The catalogue is to be obtained upon application.

Our Astronomical Column.

DR. HILL'S CUSPED ORBIT.—Dr. Hill in his "Researches on the Lunar Theory" described a certain case of satellite motion in which the orbit of the satellite relatively to the primary was cusped at first and last quarter. The period of such a satellite in the earth's case would be 205 days. Dr. Hill supposed that this was the orbit of maximum lunation, but M. Henri Poincaré later showed that still larger orbits were possible, with loops replacing the cusps.

Astr. Nach. No. 5101 contains a paper by Prof. T. J. J. See quoting results of the late Dr. John N. Stockwell, in which the latter claimed to have shown that Dr. Hill's cusped orbit was erroneous and should be replaced by a flattened oval with a period of lunation of 247⅘ days. He further asserted that Jacobi's integral (used by Dr. Hill) was based on incorrect mechanical principles. Both Prof. See and Dr. Stockwell appear to have overlooked a paper by R. Moritz in Mon. Not. R.A.S. for November, 1917, in which the latter re-investigated the cusped orbit of Dr. Hill by the method of mechanical quadratures used by Dr. P. H. Cowell for the eighth satellite of Jupiter and for Halley's comet. Needless to say, this method is independent of Jacobi's integral, and involves nothing beyond the elementary principles of accelerated motion. The result has led to the detection of a few unimportant numerical errors in Dr. Hill's work, but the accuracy of the cusped orbit is substantially verified. If Dr. Hill's figures had been rigorously exact, the minimum distance of the satellite from the earth would have been attained when the angle of motion relatively to the sun was exactly 90° from the cusp. The actual figures given by the quadrature method are 90° 6′ 51″. The error is mainly due to the small errata in Dr. Hill's work, though a little may be ascribed to the inevitable cumulative error of mechanical quadratures. It would therefore appear that Dr. Stockwell's method must involve some fallacy, since the orbit that he gives for a period of 208⅘ days is of quite a different shape from the cusped orbit, and differs little from an ellipse.

STONYHURST COLLEGE OBSERVATORY.—We have received the annual report of this observatory from the director, the Rev. A. L. Cortie, S.J. The regular observation of the sun has been continued, and the results show a steady decline in spot-activity; the disc being without spots on four days in September last for the first time since 1916. The director communicated a paper to the British Association at Cardiff on the connection between faculæ and calcium flocculi, showing that the correlation of the two is so close that the faculæ are probably the bases of the flocculi.

It will be remembered that on a former occasion Father Cortie dwelt on the importance of the latitude of sun-spots as an index of their magnetic effect on the earth. This was borne out by the spot of last month, which, although not at all abnormal in its extent, passed very near the centre of the disc, producing great magnetic disturbance and extremely bright auroræ.

The report contains an obituary notice of Bro. W. McKeon, S.J., who died on May 18, 1920. He was on the observatory staff for forty-two years, the majority of the drawings of spots made at the observatory being his work.

"L'ASTRONOMIE ET LES ASTRONOMES."—M. Auguste Collard, librarian of the Royal Observatory of Belgium, has published a useful bibliography under this title, which forms a brochure of 119 pages. It is divided under the headings: (1) Dictionaries and Encyclopædias of Astronomy; (2) Biographies of Astronomers; (3) Treatises on Astronomy, subdivided into many sections; (4) Histories; (5) Bibliographies; (6) Atlases; (7) Reviews; and (8) Tables.

The works under the various headings are not arranged in alphabetical order, but there are alphabetical indices at the end. There are also in many cases brief notes summarising the scope of the work, which are a useful supplement to the mere statement of the author's name and the title. The book promises to be useful; it is one of a series of similar works of reference published by G. Van Oest et Cie, National Library of Art and History, Brussels.

Prof. Einstein's Lectures at King's College, London, and the University of Manchester.

THE most noticeable circumstance in the lecture which Prof. Einstein delivered on June 13 at King's College on "The Development and Present Position of the Theory of Relativity" was the beauty and simplicity of his account of the theory. He made no attempt to enliven it by introducing any of the delightful illustrations which, however illuminating and attractive they may be to the popular mind, surround it with a halo of scientific romance. On the other hand, he found no occasion to have recourse to the blackboard, and he entirely omitted anything which required mathematical formulæ for its expression. He seemed, too, with earnestness and obvious sincerity to disclaim for himself any originality, and he deprecated the idea that the new principle was revolutionary. It was, he told his audience, the direct outcome and, in a sense, the natural completion of the work of Faraday, Maxwell, and Lorentz. Moreover, there was nothing specially, certainly nothing intentionally, philosophical about it. The whole theory was experimental in its origin, and the satisfaction it brought was simply in the fact that it put us in possession of a method of scientific research which not only did not bring us into conflict with observed facts, but also positively accorded with them.

The most absorbing part of the lecture was the exposition of his concept of our universe as being spatially a closed system and yet boundless. In this connection he referred to the work of Ernst Mach, who had been the first to direct attention to a distinct point in which the Newtonian theory of motion is unsatisfactory. It led Mach to endeavour to alter the mechanical equations so that the inertia of bodies should be attributed to their relative motion with reference, not to Newton's fictitious absolute space, but to the sum total of all other measurable bodies.

Prof. Einstein's modesty served only to give force to the impression which all received, and which Lord Haldane (who presided) admirably expressed, that we were welcoming not only one who is himself a man of genius, but one whose discovery is to be ranked with those of Newton, Galileo, and Copernicus—discoveries which in revolutionising thought have turned scientific inquiry in a new direction and enlarged the scientific horizon. In one aspect, as Lord Haldane pointed out, Einstein's revolution is more profound than that of the greatest of his predecessors, for while Copernicus and those who followed him corrected our deductions from phenomena within a generally accepted framework, Einstein has shown us the need of reconstituting our conception of that framework itself. It is not of choice, but of necessity, that the principle of relativity has raised a problem, and that the profoundest problem, in metaphysics—the problem of the relation of reality itself to knowledge.

After the public lecture Prof. Einstein was the guest of the Principal of King's College at a dinner given in the college. The Principal's guests included Lord Haldane, the Dean, the Vice-Principal, and many of the professors of King's College, the Astronomer Royal, Prof. Eddington, Prof. Lindemann, Prof. Whitehead, and others. In responding to his health, Prof. Einstein made an interesting revelation of his attitude to the quantum theory. This theory was, he said, presenting a difficult problem to physics, but the very nature of the difficulty served to bring into relief the attractiveness and satisfaction of the principle of relativity. That principle had served to give a simple and complete explanation of experimental facts which under any other aspect were discordant. In the quantum theory as it stood at present we were faced with discordant experimental facts, and were searching for the principle on which to interpret them.

The Adamson lecture was delivered at the University of Manchester on Thursday, June 9, by Prof. Einstein, who had been invited by the council in accordance with a Senate recommendation passed on February 3. At the opening of the proceedings the honorary degree of D.Sc. was conferred on Prof. Einstein. The lecture, which was delivered in German without an interpreter before a very large audience, was on the theory of relativity, and dealt in particular with the relation between geometry and physics. Prof. Einstein described how geometry had developed from a collection of individual theorems discovered empirically to a body of doctrine in which the logical connection between these theorems is perceived and explained. The logical structure required as its foundation a set of axioms, which constitute the residue of empiricism in the theory. The axioms of Euclid acquired such authority that in time they came to be regarded as necessities of human thought owing to the inherent nature of the mind, and thus the illusion was created that Euclidean geometry is free from anything empirical or arbitrary. On applying geometry to physics the tacit assumption was made that lengths measured by and on solid bodies correspond to lengths in Euclidean geometry. Prof. Einstein showed how the gradual discovery, through physical experiment and observation, of the fact that for objects of astronomical dimensions the axioms of Euclid do not hold good, had led first to the special, and then to the general, theory of relativity. He devoted the latter part of his lecture to the exposition of a non-Euclidean geometry (interpreting geometry in the sense of the theory of the possible positions of objects in space) in a plane, the objects in the plane being shadows of circular "beetles" inhabiting a sphere, the source of light being on the sphere, and the plane being a tangent plane at the opposite end of the same diameter.

Physico-chemical Problems Relating to the Soil.

THE Faraday Society held a general discussion on May 31 on physico-chemical problems relating to the soil. Sir Daniel Hall, in taking the chair, said that the papers to be presented would show that physico-chemical studies of soil were now as necessary as those of a purely chemical or physical nature.

Dr. E. J. Russell, director of the Rothamsted Experimental Station, in opening the discussion, gave a general review of the phenomena associated with the four main headings into which the subject was divided:—Soil moisture, organic constituents of the soil, adsorption phenomena, colloidal phenomena, etc.

The section on soil moisture was opened by Mr. B. A. Keen (Rothamsted), who dealt with the system soil–soil moisture, and pointed out that it was necessary to assume a complex colloidal coating over the soil-grains. The paper concluded with an account of the quantitative relations brought out by the freezing-point method of examining soil solution. Prof. Sven Odén (Stockholm), in a note on the hygroscopicity of clay, showed that the hygroscopicity of soils was not necessarily proportional to the total surface area of the particles. Prof. Hoagland (University of California) and Prof. Shull (University of Kentucky) forwarded papers dealing with the relation between the soil solution and the plant. The former dealt mainly

with the seasonal variations of the salts in the soil solution and with the absorption of nutrient elements by the plant, and the latter with the mechanism of osmotic phenomena associated with the root-hairs of the plant.

In the discussion of this group of papers Dr. Hackett dealt with the capillary rise of water in soils, and Mr. Wilsdon mentioned some interesting experiments on hygroscopicity and osmotic pressure.

The second group of papers, on the organic constituents in the soil, opened with a review by Mr. H. J. Page (Rothamsted) of the nature and properties of the organic matter and its influence on soil moisture, soil temperature, and the reaction, composition, and concentration of the soil solution. Prof. Odén gave an account of his important researches on humus from peat soils, in which he has shown that the term "humic acid" is chemically correct. Dr. E. J. Salisbury (University College, London) described experiments on the relations between organic matter and the vertical distribution of acidity in natural soils.

In the discussion Dr. Ormandy directed attention to the necessarily complex nature of the material used in Prof. Odén's experiments, and suggested that parallel experiments on a simpler substance like china-clay would be useful.

In the third section—adsorption phenomena—Mr. E. M. Crowther (Rothamsted) dealt with the measurement of the hydrogen-ion-concentration of acid soils, both electrometrically and with the indicators used by Clark and Lubs. Mr. E. A. Fisher (Leeds University) critically discussed the application of the adsorption formula to soil problems, in view of the empirical nature of the equation and the facility with which, by numerical modifications, it can be used to fit experimental data of phenomena which cannot be related. He showed that the modified form of Way's chemical theory, which assumes exchange of bases by double decomposition between silicates and added salts, would account for the observed phenomena.

Dr. Russell in the course of the discussion referred to the necessity for taking account of the colloidal material known to exist in soil and the consequent difficulty of accepting an exclusively chemical explanation of base exchange.

A paper in this section by Mr. C. T. G. Morison (School of Rural Economy, Oxford) on pan formation was taken as read, as was also Dr. Mellor's introductory paper in the concluding section—colloidal phenomena—on the plasticity of clays from the ceramic point of view. Prof. Odén gave an account of his work on clays as disperse systems. He described the apparatus employed, which consists essentially of a balanced plate on which the suspended particles slowly settle, the gradual increase in weight being automatically recorded. Mathematical analysis of the data enables a distribution curve to be constructed, giving the percentage of particles present between any specified range of diameters.

Mr. N. M. Comber (Leeds University) dealt with his suggestive experiments on the flocculation of soils, in which the difference between silt and clay was shown, and the conclusion drawn that clay is protected by an emulsoid of a siliceous nature.

In the concluding paper Mr. G. W. Robinson (University College, Bangor) indicated certain physical constants of soil which would be of great help when employed statistically in soil surveys.

The forthcoming publication of the papers and discussion by the Faraday Society will be of use not only to soil investigators in general, but also to members of bodies such as the Association of Economic Biologists and the Agricultural Education Association, which, among others, were invited by the Faraday Society to co-operate in the discussion.

B. A. K.

British Science Guild.

Notable Views on Present-day Problems.

WELL-KNOWN leaders of scientific thought discussed the difficult and pressing problems of the times with hopefulness, sagacity, and insight at the fifteenth annual meeting of the British Science Guild, held at the Goldsmiths' Hall on Wednesday, June 8. The president (Lord Montagu of Beaulieu) was in the chair, and there was a large and representative assembly, which welcomed with much gratification the announcement that his lordship had consented to occupy the presidency for another year.

The president, in opening, expressed their sincere sense of loss at the death of Sir Norman Lockyer, who not only took a great interest in the work of the Guild, but was also one of its most distinguished founders. They had also sustained another serious loss in the death of Sir William Mather. During the past year the Guild had given consideration to many matters of importance to scientific workers. They held that civil servants in these days ought, at any rate, to be of scientific mind or appreciate science, even though they might not be highly educated in science itself. The work of the State year by year needed more and more scientific handling and treatment, and the Civil Service as a whole should be encouraged to consult scientific men and to have recourse to scientific advice when occasion demanded. They had tried to spread their influence from London to the provinces, and so far had been very successful. They were doing their best to bring in great provincial centres, which in many ways were more promising scenes for scientific education than London itself. He was sorry they could not announce that day what they hoped last year would be the case—a conference with the representatives of Labour. They thought they had better wait for a calmer state of things before they asked either Capital or Labour or representatives of the State to consider their mutual relations to each other and to science. He thought they ought to ask themselves in regard to the generally unsettled state of the country, in fact of nearly all civilised countries to-day, whether it was possible to go on putting up our scale of living for all classes and to reduce our hours of work at the same time; and, what was more serious in many cases, reduce the output more than in proportion to the number of hours put in. It was quite certain that in this country, if we were to compete with the world and maintain a high standard of living at the same time, we must increase our output per man of machine work even if we worked shorter hours. That was a very difficult problem to solve, but he did not despair with the help of science, in some trades at any rate, of its solution. Then they had to aim at the better education of all classes in scientific facts and inculcate more and more the scientific habit of mind. But our system of education must be less of the parochial and insular kind and more scientific, broad, and world-wide in outlook. The difficulty to-day, he thought they would agree, was that in many of the great subjects which they had to consider facts were very difficult to get at. Science aimed at the truth, and in social and political matters, as well as in scientific matters, if they knew the real facts, a

solution was not always easy, but at any rate it was made much easier. Education was the great hope of the future, and in that education science must play a prominent part.

The annual report of the executive committee having been adopted, on the proposition of Lord Avebury, seconded by Sir John Cockburn, Dean Inge delivered a striking address entitled "The Road to Ruin and the Way Out." It was obvious, he said, that the first half of the subject was easier than the second. The road to ruin was the road along which we were travelling; the way out was not easy to find, and possibly difficult to follow. It was useless to utter mere jeremiads, and it took a great deal to destroy a powerful nation. Medical science taught that the more acute and violent the disease, the more vigorous was the production of anti-toxins, and it added the comforting assurance that if the constitution survived an invasion of poisonous microbes the patient would probably have acquired immunity for a considerable time to come against that particular disease. Perhaps it might be so in our social and political life. Very few politicians and sociologists allowed nearly enough for the swing of the pendulum. The false doctrine of continuous progress had led most of us to treat the flowing tide as a permanent encroachment of the sea. The direction in which the tide was flowing was called "progress," the opposite direction "reaction." History should have taught us better. Political experiments were welcomed enthusiastically until they had been tried; when they were in operation disillusionment began at once. The more revolutionary the change, the quicker was the process of conversion, so that it was almost a commonplace that the young firebrands of a revolutionary age—men like Wordsworth, Coleridge, Southey, Carlyle, and Ruskin—often ended as uncompromising Tories. We had not by any means done with aristocracy and monarchy in Europe. Human nature remained the same, and it tried one way after another to misgovern itself and mismanage its affairs. The first thing necessary was diagnosis. It was obvious that the most ruinous feature of modern society was the strike. This country depended for its very existence on being able to export manufactures to pay for imported food, and our power of exporting manufactures was rapidly disappearing. No scheme of "redistributing" property, however drastic and iniquitous, could have the slightest effect in preventing the starvation of a country which could not feed itself and would not work under economic conditions. There were two forces available which could bring a country out of the worst of holes. These were science and religion. They in that Guild were chiefly concerned in the application of scientific knowledge and scientific method to British industry. We were always abusing ourselves for being behind the time—so unlike the Germans, for example. That was the British lion's little way; he was always lashing himself with his tail and calling himself a fool and a slacker, until foreign nations came to believe him. When they tried conclusions with him they found that he was by no means such a fool as he looked, and they complained that it was very unfair. Still, he had no doubt that this Guild would continue to find plenty to do. But behind scientific method there was something deeper—scientific faith and the scientific temper. They must not shut their eyes to the fact that science had many enemies; science as such was disliked by many people. But science had one enormous advantage over its old enemies—it had the nature of things on its side, and wherever it was disregarded and disobeyed it did not talk, but struck. Dame Nature was a good teacher, but her fees were high. It was worth a great deal to impart the scientific way of looking at things—the scientific conscience (should he call it?) in education. He was himself an enthusiastic humanist, and he should be sorry indeed if science were to oust humanism in our education; he should be sorry for the sake of science itself, for a man could scarcely be a scientific worker without being also a humanist; but science we must have as a part of everyday training. Only he would suggest that the faith and temper and conscience of science were a more important acquisition than any mere facts. We wanted to teach the next generation to respect all facts wherever they might find them. A scientific training marked a man who would not commit his soul and his conscience to the keeping of anyone, whether priest or Labour official. We needed this independence badly; some whole classes were in danger of losing it. The other force that might help us out of the mud was religion or, as he should prefer to say, Christianity. The fundamental message of Christianity was that we must get our values right, and that if we got our values right nothing else would be seriously wrong. Science was daughter to one of the absolute and eternal values—truth; art paid its homage to another—beauty; and morality to the third—goodness. Religion consecrated and endeavoured to humanise those three absolute values which it regarded as revelations of the nature and character of God. Our generation might be very stiff-necked and perverse, but sooner or later wisdom would be justified of her children. They must just go on giving their testimony, whether men would hear or whether they would forbear. "The mills of God grind slowly, but they grind exceeding small."

Sir Richard A. S. Redmayne (chairman of the Imperial Mineral Resources Bureau) next spoke on "The Importance of Research in the Development of the Mineral Industries." He remarked that the cessation of hostilities was succeeded almost at once by a period of feverish industrial activity—it would be erroneous to apply the words "general prosperity"—to be followed by a cycle of great depression. The demand for goods was great, but production was falling. What was the explanation? It lay, he thought, in a combination of circumstances:—(1) A feeling of insecurity due to unsettled political and financial conditions. Hence a disposition to conserve rather than to utilise in commercial ventures such capital as is available. (2) The incidence of the rate of exchange. (3) The high cost of production consequent on the high cost of living and the higher standard of comfort demanded by the labouring classes (and rightly so demanded) than formerly obtained. (4) The lower, and still apparently decreasing, productive power of Labour. The first two conditions would in part right themselves in process of time as the various political problems were solved, or partly solved, and rates of exchange would then tend towards the normal; but a very great deal depended upon the last two conditions, as the future position of production was not easy to forecast. Higher and cheaper production were difficult desiderata to obtain in view of the high rate of wages now ruling and the diminishment in working time either achieved or claimed by the manual workers of the day, and these were demands which were not likely to show much abatement in the future. What was the solution? The answer he ventured to give was "research," to discover by research cheaper means of production, and, by research, to create new outlets. How should research be organised and carried out? Empirical investigations must be based upon a scientific foundation if they were to be of ultimate and practical value. It had, however, been well said that if an investigator did not possess the inventive as well as the purely

scientific faculty, the value of the work was apt to be largely lost. The discovery of new things was one matter, and was a characteristic of the academic type of mind; the discovery of new uses for things was another matter, and was typical of the commercial mind. In this work of research the universities were peculiarly fitted to take an important—a leading—part. The research should not necessarily be pursued along definite lines with a definite object in view; the great discoveries were not made in that way. The Department of Scientific and Industrial Research might well endow university scientific research on chemical, metallurgical, and engineering work, supervising and co-ordinating and publishing the results. Effort was largely commensurate to the prize offered, and the discoverer should be rewarded for his labour and genius; but that would be a matter easy of arrangement. Research associations undoubtedly performed useful, even highly valuable, functions, but the wind of science bloweth where it listeth, and the time was ripe for a realisation of the fact that scientific research could not profitably be hampered by restrictions confining the efforts of those who were employed therein. It was of the essence of research that it should be free and untrammelled.

Sir Richard Gregory proposed a vote of thanks to the speakers, and remarked that the addresses of their two distinguished new vice-presidents were of a very inspiring and instructive character. Dean Inge had referred to the fact that a disease produced in the organism an anti-toxin to fight it, and the anti-toxin, Sir Richard suggested, that existed now for certain social diseases was the British Science Guild. It was really a British Efficiency Guild, and in the forefront of its activities must be the promotion, not only of research, but also of the application of research. We had numerous scientific societies, each of which was concerned with adding to scientific knowledge by research, but there was no society or organisation in the kingdom which existed, as the Guild existed, to see that knowledge thus gained was made good use of for national welfare. That was why the Guild could perform a most useful service in bringing before the public the value of research, science, truth, and righteousness to a nation that desired to maintain a leading position in the world. The trade unions referred to by Dean Inge and Sir Richard Redmayne were not trade unions, but wage-unions. If they were really trade unions, and if Labour were united with science to increase production instead of merely scrambling for pence on a Tom Tiddler's ground, then together they would be the greatest force in our Constitution.

On the proposition of Lady Lockyer, hearty thanks were also accorded to the Warden and Court of Assistants of the Worshipful Company of Goldsmiths for the use of their hall. Lady Lockyer paid a graceful tribute to the munificence of the Goldsmiths' Company in educational and other directions, and made an appeal to those who were not members of the British Science Guild to become associated with it, whether they were scientific workers or not.

University and Educational Intelligence.

Cambridge.—Mr. E. K. Rideal, Trinity Hall, has been appointed to the Humphry Owen Jones lectureship in physical chemistry. Dr. L. Cobbett, Trinity College, has been re-appointed University lecturer in pathology.

The Rede lecture was delivered on June 9 by Sir Napier Shaw on "The Air and its Ways." The lecturer likened the atmosphere to a steam-engine, for which the heated surface of the earth and sea acted as boiler, the cold polar regions and the cold upper air as condenser, and the normal winds and cyclonic depressions as flywheel. The normal winds were the equatorial belt of air passing westwards and the circumpolar motion of the upper air travelling eastwards. Between them were the anticyclonic circulations which, like the driving-belts of tanks, carried forward the westward moving air of the equatorial, and the eastward moving air of the polar, circulation.

Manchester.—At the meeting of the council of the University on June 8 the following appointments were made:—Miss Winifred S. Clarke, lecturer in education; Miss May A. B. Herford, lecturer in classical archæology; Mr. S. Williams, assistant lecturer in botany; Mr. W. Cartwright, assistant lecturer in metallurgy; Mr. P. I. C. Gibson and Mr. A. Haworth, demonstrators in pathology; and Miss Georgina May Duthie and Mr. R. C. Shaw, demonstrators in anatomy.

Mr. W. E. Alkins has resigned his appointment as lecturer in metallurgy as from September 29 next.

Oxford.—Mr. W. Brown, Christ Church, has been elected Wilde reader in mental philosophy.

St. Andrews.—The honorary degree of LL.D. is to be conferred on July 12 upon the following:—Prof. W. M. Bayliss, Sir William Henderson (chairman of Dundee Technical College), Emeritus Prof. D. Macewan, and Prof. A. N. Whitehead.

The University of Wales has decided to confer the honorary degree of D.Sc. upon Prof. T. W. E. David, Sir J. J. Dobbie, and Prof. A. Gray.

Mr. R. J. Pye-Smith, formerly professor of surgery in the University of Sheffield, has bequeathed the sum of 1000*l*. to the University in question for a chair in surgery.

Mr. A. MacCullum, of Edinburgh, who gave 25,000*l*. during his life towards the erection of the new Royal (Dick) Veterinary College buildings in Edinburgh, has bequeathed, under certain conditions, on the death of his wife, a further sum of 10,000*l*. for equipping and furnishing the college buildings.

The following appointments have been made in connection with the Royal College of Surgeons of England:—Dr. F. W. Edridge-Green, Mr. V. Z. Cope, and Prof. T. Swale Vincent, Arris and Gale lecturers; Prof. S. G. Shattock, Erasmus Wilson lecturer; Sir Arthur Keith, Arnott demonstrator; and Sir Charles A. Ballance, Thomas Vicary lecturer.

The London School of Economics and Political Science is prepared to award one or more post-graduate studentships, of value up to 200*l*. a year for one or two years, to suitable candidates who wish to combine research with a certain amount of teaching at the school, or to follow approved courses of study with the view of qualifying themselves for such teaching. Applications, stating qualifications and giving two references, should be made as soon as possible to the Director, London School of Economics and Political Science, Clare Market, London, W.C.2.

The Selborne Society has issued a list of lectures, most of them illustrated by lantern-slides, which its lecturers are prepared to give during the coming

winter season. The officers of the society deliver five lectures dealing with its objects and activities, *e.g.* Gilbert White and Selborne, the Brent Valley bird sanctuary which the society has recently secured, the value of science to the community and suggestions for the organisation of natural history societies, and archæological and historical rambles. Beyond these official lectures there is available a long list of lecturers who cover a wide range of subjects. Prof. J. R. Ainsworth-Davis lectures on science and agriculture; Capt. W. H. S. Cheavin on nature study, particularly in its microscopic aspects; the Rev. J. T. W. Claridge on stars and comets, and he also gives a historical lecture entitled "Some Famous Astronomers"; Mr. O. H. Latter deals with the nature study of sand dunes, wasps, and evidences of evolution; Prof. J. T. MacGregor-Morris lectures on electricity in home-life and in nature; Mr. F. Martin-Duncan deals with the natural history of the sea and the forest, and particularly with the insect world; Mrs. R. A. Proctor lectures on astronomy in everyday life and the story of the moon; Mr. J. J. Ward deals with pond-life, insects, animal life and evolution, and the wonders of wild and garden flowers; Mr. W. M. Webb, in addition to the lectures on the objects of the Selborne Society, which as general secretary of the society he delivers, also gives lectures on evolution in dress and plumage, mimicry, and protective resemblance in animals. Such is a selection from the list of the better-known lecturers. Further information regarding the lectures can be obtained from Mr. P. J. Ashton, extension secretary, 72 High Street, Bromley, Kent.

IN view of the announcement made in NATURE of April 14 last, p. 220, that the Finsbury Technical College will not be closed in July next, it is of interest to read the correspondence which passed during last winter between the City and Guilds Institute and the London County Council on the subject. It has been published in full in the forty-first annual report of the council of the City and Guilds Institute, and is preceded by a statement by the council on the circumstances under which it was decided to close the college. In the face of the decision of the London County Council to make the Northampton Polytechnic its engineering school and the tendency of the policy of the Board of Education to substitute public for private effort in education, it was not considered feasible or practicable to raise the 13,000*l.* per annum required in excess of pre-war expenditure. However, towards the end of last year the education authorities of the London County Council reviewed the matter, and decided that since a depletion of the facilities for technical education was highly undesirable they would assist the college. Various minor conditions have been imposed, but in effect the London County Council will contribute a sum of 10,000*l.* per annum for five years provided that the City and Guilds Institute finds 3500*l.* per annum for a similar period for the maintenance of Finsbury Technical College. The council of the City and Guilds Institute expresses the hope that the City Corporation and the contributory livery companies will continue to give their support in order to make possible the development of their educational schemes. An interesting list in the report is that showing the contributions made yearly to the institute since 1878. The Goldsmiths' Company heads the list with contributions amounting to 275,508*l.*; then come the Clothworkers', Fishmongers', and Mercers' Companies with gifts ranging from 152,000*l.* to 101,000*l.* The remainder of the report is devoted to a review of the academic activities of the City and Guilds (Engineering) College during the year 1919–20.

Calendar of Scientific Pioneers.

June 16, 1889. Gaetano Cacciatore died.—The able director of the Palermo Observatory, in which position he succeeded his father in 1843, Cacciatore extended the observatory and contributed memoirs to the Società degli Spettro-scopisti.

June 18, 1816. Thomas Henry died.—Henry was a Manchester apothecary, the translator of Lavoisier's chemical essays, and the first to observe the use of carbonic acid to plants. In 1781 he became the first secretary of the Manchester Literary and Philosophical Society, and in 1807 was chosen president.

June 18, 1905. Per Theodor Cleve died.—Professor of chemistry in the University of Upsala, Cleve was well known for his researches on the rare earths. He investigated the compounds of yttrium, erbium, thorium, lanthanum, and didymium, and he showed that scandium, discovered by Nilson, was identical with the ekaboron of Mendeléeff.

June 19, 1715. Nicolas Lemery died.—The contemporary of Mayow and Homburg, Lemery wrote a "Cours de Chimie," which was translated into various languages and passed through thirteen editions in his lifetime. This work, from which the fancies of the alchemists were excluded, was one of the first in which chemistry was divided into organic and inorganic. Lemery was a Paris apothecary.

June 19, 1820. Sir Joseph Banks died.—For more than forty years president of the Royal Society, Banks was indefatigable in his exertions on behalf of natural science. He made four oversea journeys himself, assisted various expeditions, founded the African Society, and advised George III. as to the Kew Gardens. His library and collections were bequeathed to the British Museum.

June 19, 1844. Etienne Geoffroy Saint-Hilaire died.—The pupil of Daubenton and Haüy and the friend of Cuvier, in 1793 Saint-Hilaire became professor of zoology in the Musée d'Histoire Naturelle. In 1798 he accompanied Napoleon to Egypt. Admitted to the Academy of Sciences in 1807, he afterwards became professor of zoology and comparative anatomy in the Faculty of Sciences. Among his most important works was his "Philosophie Anatomique" (1818–22).

June 20, 1794. Félix Vicq d'Azyr died.—The successor of Buffon in the Paris Academy of Sciences and physician to Louis XVI., Vicq d'Azyr wrote an important work, "Discours sur l'anatomie," in which he stated in a masterly way the methods of biological science.

June 21, 1846. James Marsh died.—The assistant to Faraday at the Royal Military Academy, Woolwich, Marsh invented electromagnetic apparatus, and also the quill percussion tube for ships' cannon, and in 1836 discovered the Marsh test for arsenic.

June 21, 1857. Louis Jacques Thénard died.—Born in poor surroundings, Thénard was assisted by Vauquelin, and gradually rose to a high place among French chemists. He held chairs at the Ecole Polytechnique, the Collège de France, and the Sorbonne, and though he did important work on the compound ethers and discovered hydrogen peroxide, he was, above all, a great teacher.

June 21, 1874. Anders Jons Ångström died.—Ångström held the chair of physics in Upsala University and was secretary to the Royal Society there. He did pioneering work in spectroscopy, in 1862 discovered the existence of hydrogen in the sun, and in 1868 published his map of the normal solar spectrum. Knut Johan Ångström (1857–1910), also a well-known physicist, was his son.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, June 9.—Prof. C. S. Sherrington, president, in the chair.—Prof. C. S. **Sherrington**: Break-shock reflexes and "supra-maximal" contraction-response of mammalian nerve-muscle to single-shock stimuli. The maximal twitch-contraction of tibialis anticus muscle (cat) evoked by a single break-shock applied to the cut motor nerve exceeds the contraction evoked reflexly (spinal preparation) by a single break-shock applied to an afferent nerve. This is due to the reflex response being tetanic in nature. If the break-shock is strong it excites, even when applied to the motor nerve, a response of tetanic quality. The so-called "over-maximal twitch," now termed "supra-maximal response," is a response of this kind. A reaction of like kind probably obtains in the afferent nerve when the single-shock applied to it is of comparably high value. In this case there is also a tetanic reaction from afferent nerve-fibres themselves. With weaker break-shock stimuli the origin of the tetanic character of the reflex discharge lies in the centre itself. It arises there from a "charge" process which is relatively long-lasting in comparison with the cycle of a nerve-impulse, and increases in intensity and duration with the number of afferent fibres excited.—R. J. **Ludford** and J. B. **Gatenby**: Dictyokinesis in germs-cells, or the distribution of the Golgi apparatus during cell-division. Maturation mitoses in the germ-cells of Cavia, Mus, Helix, Limnæa, and Stenobothrus were examined. In all cases the Golgi apparatus breaks up into its constituent granules, and these are distributed haphazardly to the two daughter-cells at mitosis. In no case examined are they divided between the daughter-cells as equally as are the chromosomes. Hence the Golgi apparatus takes no important part in the transmission of factors from cell to cell.—Dr. F. W. **Edridge-Green**: The effect of red fatigue on the white equation. A white equation is formed by means of a mixture of a red of λ6670–6770 Å., a green of λ5144–5156 Å., and a violet of λ4250–4267 Å., matching a simple white. When the eye is fatigued with light viewed through a red glass, or with pure spectral light in the region of λ6700 Å., and the equation is again made, about half the amount of green is required. The white equation and its match cannot be due to similar physiological processes, or both would change in the same ratio. When the fatiguing light is in the region of λ7800 Å., no difference is seen between the mixed and simple white.—E. **Ponder**: A method for investigating the hæmolytic activity of chemical substances. The relation between the time taken by a given quantity of hæmolytic substance and the temperature at which it acts is expressed by a hyperbola. The relation between the constants of such a hyperbola and the quantity of hæmolytic substance to which it applies are given. Certain general relations hold for all substances examined. Experimental and calculated results are compared.—W. H. **Pearsall**: The development of vegetation in the English lakes, considered in relation to the general evolution of glacial lakes and rock basins. The English lakes are of the same age (glacial), of similar origin, and lie among rocks possessing relatively uniform characters. The differences they show are due to variations in the rates of erosion and sedimentation of the lake basins; therefore it becomes possible to describe the stages in the post-glacial development of a rock basin, and also of its vegetation. The differences observed between primitive and evolved lakes are regarded as being dependent upon their physical condition.

Association of Economic Biologists, June 4.—Sir David Prain, president, in the chair.—F. L. **Engledow**: The problem of increasing the yield of cereal crops by plant breeding. Aspects of experimental investigation, such as breeding for disease resistance, non-lodging, or high intrinsic yield, were considered, and the great difficulty of obtaining any simple criterion for so complex and elusive a total resultant as "yield" was emphasised. Bevan's studies on the migration coefficient as an index of yield were destructively criticised. The relation of yield to the weights of individual grains, to the number of grains per ear, to the number of ears per plant, and to the tillering of the plant was considered. At present comparative estimates are based on "yield per acre," but the author's work suggests that "yield per tiller" may, perhaps, be a better measure, "yield" itself being estimated in terms of starch, carbon, or some other chemical criterion, in place of the commercial standards now accepted.—C. B. **Saunders**: Problems of seed testing. The technique adopted at the official seed-testing station for the testing of purity and germinative capacity was described. Many problems arise in this work of both a mechanical and biological nature. Simple and effective instruments for sampling and non-selective counting are required, as well as selective mechanical devices for the extraction of dodder and other seeds from a mixture. Biological problems largely concern the relation of seed germination to environmental factors, and the apparent inconstancy shown in this relation. Thus seeds of apparently the same kind may under standardised conditions differ considerably not only from year to year and from month to month, but also from sample to sample, and may show periodicities and external factor relationships which give rise to a very great complexity of varying combinations. The whole technique is empirical, and much fundamental research is needed.

CAMBRIDGE.

Philosophical Society, May 16.—Prof. A. C. Seward, president, in the chair.—Dr. E. H. **Hankin**: The soaring flight of dragon-flies. From observation it appears improbable that undiscovered wing-movements or ascending currents of air can be accepted in explanation of soaring flight. Alterations in the amount of sunlight, even when slight, make considerable differences in the flight of dragon-flies. Lowering of the abdomen as a brake on speed in catching prey, etc., is a common phenomenon. Dragon-flies, flying-fishes, and birds all exhibit soaring flight, and in each class evidence is accumulating that low-speed flight depends on the presence of sunshine and high-speed flight on the presence of wind. If not identical, the speeds attained in the three classes are comparable.—C. G. **Lamb**: Note on secondary sexual characters in the Diptera, with a description of a novel type. The author discussed some points in the structure of the hypopygium in flies, and gave a description of some secondary characters in a new genus of Dolichopodidæ which were situated centrally instead of peripherally.—L. A. **Borradaile**: A note on the mouth-parts of certain Decapod crustaceans. Some Decapods, as Hapalocarcinus and Porcellana, seize food-particles directly; others, as Pinnotheres and the Pontoniinæ, take it from sessile organisms. The mouth-parts of the former are modified for their mode of feeding. Similar modifications are not found in the latter, possibly because their food reaches them entangled in strings of mucus. Porcellana has no such jaw-reduction as is found in Hapalocarcinus, and this is as yet unexplained.—J. **Gray**: Hermaphrodite sea-urchins.—A. B. **Appleton**: (1) Preliminary note on the development of muscle, bone, and body-weight in

sheep. A summary was given of some results obtained in conjunction with Mr. J. Hammond over a number of years. The data brought forward referred to parts much utilised in the judging of sheep, viz. "hind-limb," "loin," "behind the shoulder," and "over the shoulder." In normal rams the muscles increase in weight after birth faster than the associated bones, while the ratio found in adults is nearly attained at the age of three months. From birth onwards the carcass forms an increasing proportion of the live-weight of the animal. The development of the hind-limb proceeds as a wave of growth passing upwards from below. Histological examination of the muscles in the prize animals shows that a very large amount of fat is present between the muscle-fibres in addition to that between muscle-bundles. Fat in the popliteal space and around the pelvis was notably increased. The characteristic "feel" and appearance of prize animals appear to be due to bone reduction as well as to fat and muscle increase. (2) The alleged inheritance of an acquired character in man. Photographs were shown of ankle-joints of new-born English children. Features are present which, from their presence in the newly born natives of India, have been claimed as the inheritance of a character acquired by their parents through adoption of the squatting posture. This cannot be the case in the English child. The features found in the new-born child are held to be the anatomical outcome of the normal attitude of the fœtus. (3) The so-called gluteus maximus of Tarsius. This is stated to be a compound muscle, since it includes the femoro-coccygeal and caudofemoral muscles. This is the interpretation given of the position of the great sciatic nerve, which passes through the gluteus maximus. In lemurs and in the primitive insectivore Tupaia a similar condition was found.—H. P. **Waran**: The effect of a magnetic field on the intensity of spectrum lines, ii. The earlier work of Kent and Frye on the subject is discussed and the invalidity of conclusions obtained under adverse experimental conditions proved by proper control experiments. Further study of the phenomenon conducted in a quartz tube are described. The enhancing effect of the magnetic field on the negative glow bands of nitrogen and the Balmer series of hydrogen are described, and the Balmer series is suggested to be mainly the radiations of the atom while the gas is at a high pressure. Experiments with a condensed discharge have proved the difference between its effect and that introduced by the magnetic field.—C. G. F. **James**: The theoretical value of Sutherland's constant in the kinetic theory of gases.—T. S. **Yang**: Orthogonal systems and the moving trihedral.

Dublin.

Royal Irish Academy, May 23.—Prof. Sydney Young, president, in the chair.—G. A. J. **Cole**: The problem of the Bray series. The stratigraphical position of the series of quartzites and slates that form Bray Head and Howth in the Dublin district has always seemed obscure. While the few organic remains indicate a Cambrian age, these rocks appear in places to overlie Ordovician strata, and they have suffered no invasion or metamorphism by the closely adjacent Leinster granite. Examination of the successive MS. notes in records of the Geological Survey of Ireland shows how the problem was under discussion between 1855 and 1865. In the present paper it is suggested that the Bray series has been brought into position along a thrust-plane from the south-east during the later phases of the Caledonian folding, and that the outlying mass of Carrickgallogan is a "klip" resting, as Du Noyer believed, on Ordovician slates.

Paris.

Academy of Sciences, May 23.—M. Georges Lemoine in the chair.—C. **Moureu**, M. **Murat**, and L. **Tampier**: Acrylic acid and acrylic esters. Halogen propionic acids and esters. Starting with pure acrolein, now readily obtainable in quantity, a method of preparing acrylic acid is described based on the intermediate production of β-chloropropionic acid. The acrylic acid was purified by repeated fractional crystallisation, and its physical constants were determined. The pure acid combines quantitatively at the ordinary temperature with the halogen acids.—A. **Blondel**: The topographical representation of the couples of alternating-current motors.—**Prince of Monaco**: Official visit to the United States.—C. **Guichard**: The 3I systems all the right lines of which belong to a linear complex.—M. Jean Massart was elected a correspondant for the section of botany in succession to the late M. Pfeffer.—G. **Julia**: The discontinuities of the solutions of certain Fredholm's equations.—P. **Humbert**: Hypergeometrical polynomials.—P. **Lévy**: Some questions of the functional calculus.—E. **Esclangon**: The aurora borealis of May 14–15, 1921, observed at Strasbourg.—M. **Luce**: Chemical reactions and radius of curvature. A continuation of work previously published on the same subject. It is shown that the influence of the curvature of a solid is the same in liquids as in gases, and that the data in both cases can be expressed by a similar formula.—M. **Bridel**: The application of the law of mass action to the results obtained in the reaction of β-galactosidase on galactose in solution in propyl alcohol. The application of the law of mass action to this reaction shows that in many cases equilibrium had not been reached when the experiments were stopped. For the stronger alcohols it would be necessary to prolong the experiments for months, or even years, to attain equilibrium.—A. **Tian**: A cause of dispersion of the colloid in an important class of hydrosols.—A. **Boutaric** and M. **Vuillaume**: The flocculation of colloidal arsenic sulphide. Principle of a method of study. The opacity of the solutions was measured in a Féry spectrophotometer; absorption curves are given showing the influence of time, of excess of hydrogen sulphide, and of excess of arsenious oxide. To have strictly comparable flocculation the colloidal solution must contain neither free sulphuretted hydrogen nor arsenious oxide.—E. **André**: Contribution to the study of the oil from grape pips. The chemical and physical constants of eleven samples of oil from different sources are given; the figures show great divergences, and it is evident that the composition of this oil varies considerably with the kind of grape.—P. **Gaubert**: The artificial coloration of crystals obtained by the solidification of a fused substance and on crystalline diffusion.—F. **Ehrmann** and J. **Savornin**: The stratigraphical scale of the Kabylie des Babors.—R. **Dongier**: The simultaneous oscillations of the pressure and wind at the top of the Eiffel Tower, and their relation with the squall surface (J. Bjerkness) of a depression. A reproduction of the curves of the recording instruments, showing the atmospheric pressure, wind velocities at the summit and base of the tower, and temperatures on September 15, 1906. The conclusions resulting from a detailed examination of these diagrams are in agreement with the theory of J. Bjerkness.—Ad. **Davy de Virville** and R. **Douin**: The modifications of form and structure of liverworts submerged in water. Seven species have been studied, and were found to adapt themselves to the new medium, undergoing remarkable changes in development, size, and structure.

If these forms had been met with in Nature, without knowing their history, they would have been described as varieties, and even as new species.—P. **Choux**: A new leafless Asclepias from the north-west of Madagascar.—S. **Jonesco**: Contribution to the study of the physiological *rôle* of the anthocyanins.—A. **Lumière** and H. **Couturier**: Anaphylaxy in plants. Experiments are described and illustrated by reproductions of photographs proving definitely that an anaphylactic state can be established in plants.—R. **Courrier**: The interstitial gland of the testicle and secondary sexual characters in fishes.—Mlle. **Larbaud**: New technique for the inclusions and microscopical preparations of vegetable and animal tissues. The use of butyl alcohol instead of ethyl alcohol is proposed for dehydrating the tissues. It has the advantage of dissolving paraffin wax, thus rendering unnecessary the use of xylene or toluene, and the number of treatments can be reduced from six to two.—G. **Truffaut** and N. **Bezssonoff**: Increase in the number of *Clostridium pastorianum* in soils partially sterilised by calcium sulphide.—R. **Poisson**: Researches on the determinism of the loss of the faculty of flight in the aquatic Hemiptera.

ROME.

Reale Accademia nazionale dei Lincei, April 3.—V. Volterra, vice-president, in the chair.—Papers by fellows:—G. **Castelnuovo**: Abelian functions, iii.: Jacobi's varieties.—C. **Segre**: The principal lines of a surface of S_5 and a characteristic property of Veronese's surfaces, i.—F. **Severi**: Theory of simple integrals of first species belonging to an algebraic surface, ii.—Communicated through fellows:—G. **Rovereto**: Erosive development considered as starting from a fundamental surface.—C. **Jucci**: Metabolism of true royal forms in the society of the Termites, ii.—Prof. Corbino read an account of the life and work of the late Prof. Augusto Righi, who died on June 8, 1920, and a similar notice relating to the late Prof. Michele Rajna, who died on September 29, 1920, was contributed by Dr. Legge. Among additions to the Academy library were mentioned treatises on dynamics of systems by Prof. Maggi and on statics of dams for lakes and science of construction by Prof. Guidi, presented through Prof. Levi Civita, in addition to several mathematical works.

Books Received.

Solvency or Downfall? Squandermania and its Story. By Viscount Rothermere. Pp. xi+160. (London: Longmans, Green and Co.) 2*s*.

Dairy Bacteriology. By Prof. Orla-Jensen. Translated from the second Danish edition by P. S. Arup. Pp. xii+180. (London: J. and A. Churchill.) 18*s*. net.

Tables, Factors, and Formulas for Computing Respiratory Exchange and Biological Transformations of Energy. Prepared by Thorne M. Carpenter. (Publication No. 303.) Pp. 123. (Washington: Carnegie Institution.) 2 dollars.

Index to United States Documents relating to Foreign Affairs, 1828–61. By Adelaide R. Hasse. (In three parts.) Part iii.: R to Z. (Publication No. 185, part iii.) Pp. 1331–1980. (Washington: Carnegie Institution.) 7 dollars.

Principes de Biologie Végétale. By Prof. Noël Bernard. (Nouvelle Collection scientifique.) Pp. xii+212. (Paris: F. Alcan.) 8 francs net.

Microbiology: A Text-Book of Microörganisms General and Applied. Edited by Prof. Charles E. Marshall. Third edition, revised and enlarged. Pp. xxviii+1043+1 plate. (London: J. and A. Churchill.) 21*s*. net.

From a Modern University: Some Aims and Aspirations of Science. By Prof. Arthur Smithells. Pp. 124. (London: Oxford University Press.) 12*s*. 6*d*. net.

The Commercial Apple Industry of North America. By J. C. Folger and S. M. Thomson. (Rural Science Series.) Pp. xxii+466+xxiv plates. (New York: The Macmillan Co.; London: Macmillan and Co., Ltd.) 18*s*. net.

L'Astronomie et les Astronomes. By Auguste Collard. Pp. viii+119. (Bruxelles: G. Van Oest et Cie.)

Pneumatic Conveying: A Concise Treatment of the Principles, Methods, and Applications of Pneumatic Conveyance of Materials. By E. G. Phillips. (Pitman's Technical Primers.) Pp. xii+108. (London: Sir I. Pitman and Sons, Ltd.) 2*s*. 6*d*. net.

Tanning Materials. With Notes on Tanning Extract Manufacture. By Arthur Harvey. Pp. vii+182. (London: Crosby Lockwood and Son.) 15*s*. net.

Perfumes, Essential Oils, and Fruit Essences Used for Soap and other Toilet Articles. By Dr. Geoffrey Martin. (Manuals of Chemical Technology, X.) Pp. vii+138. (London: Crosby Lockwood and Son.) 12*s*. 6*d*. net.

Elements of Practical Geometry. A Two Years' Course for Day and Evening Technical Students. By P. W. Scott. Pp. v+185. (London: Sir I. Pitman and Sons, Ltd.) 5*s*. net.

A Geological Excursion Handbook for the Bristol District. By Prof. S. H. Reynolds. Second edition. Pp. 224. (Bristol: J. W. Arrowsmith, Ltd.; London: Simpkin, Marshall and Co., Ltd.) 5*s*. net.

Exponentials Made Easy; or, The Story of "Epsilon." By M. E. J. Gheury de Bray. Pp. x+253. (London: Macmillan and Co., Ltd.) 4*s*. 6*d*. net.

A Text-Book of Inorganic Chemistry. Edited by Dr. J. Newton Friend. Vol. ix., part ii.: Iron and its Compounds. By Dr. J. Newton Friend. (Griffin's Scientific Text-books.) Pp. xxv+265. (London: C. Griffin and Co., Ltd.) 18*s*.

Tuberculosis: Its Prevention and Home Treatment. By Dr. H. Hyslop Thomson. (Oxford Medical Publications.) Second edition. Pp. ix+99. (London: H. Frowde and Hodder and Stoughton.) 4*s*. net.

Year-Book of the Royal Society of London, 1921. (No. 25). Pp. iv+201. (London: Harrison and Sons, Ltd.) 7*s*. 6*d*.

Library of Congress. A List of Geographical Atlases in the Library of Congress, with Bibliographical Notes. Compiled under the direction of Philip L. Phillips. Vol. iv. Pp. clxiii+639. (Washington: Government Printing Office.) 1.25 dollars.

Biochemistry: A Study of the Origin, Reactions, and Equilibria of Living Matter. By Prof. Benjamin Moore. Pp. vii+340. (London: E. Arnold.) 21*s*. net.

Fabre, Poet of Science. By Dr. G. V. Legros. Translated by Bernard Miall. Second impression. Pp. 352. (London: T. Fisher Unwin, Ltd.) 8*s*. 6*d*. net.

Oxford University Junior Scientific Club. Electrons and Ether Waves. Being the Twenty-third Robert Boyle Lecture, on May 11, 1921. By Sir William Bragg. Pp. 14. (London: Oxford University Press.) 1*s*. net.

Oxford and the Rural Problem. Being the First Sidney Ball Memorial Lecture, December, 1920. By the Right Hon. Sir Horace Plunkett. (Barnett House Papers, No. 6.) Pp. 18. (London: Oxford University Press.) 1*s*.

Hyperacoustics. By John L. Dunk. Division ii.: Successive Tonality. Pp. xi+160. (London: J. M. Dent and Sons, Ltd.; New York: E. P. Dutton and Co.) 5s. net.

Greek Medicine in Rome. The Fitzpatrick Lectures on the History of Medicine, delivered at the Royal College of Physicians of London in 1909–10, with other Historical Essays. By the Right Hon. Sir T. Clifford Allbutt. Pp. xiv+633. (London: Macmillan and Co., Ltd.) 30s. net.

The Psychology of Industry. By Dr. James Drever. Pp. xi+148. (London: Methuen and Co., Ltd.) 5s. net.

Motya: A Phœnician Colony in Sicily. By Joseph I. S. Whitaker. Pp. xvi+357. (London: G. Bell and Sons, Ltd.) 30s. net.

Diary of Societies.

THURSDAY, JUNE 16.

INSTITUTE OF PATHOLOGY AND RESEARCH (at St. Mary's Hospital), at 4.30.—Prof. W. Bulloch: Use and Abuse of Scientific Medical Literature.

ROYAL SOCIETY, at 4.30.—Prof. H. B. Dixon, Dr. C. Campbell, and Dr. A. Parker: The Velocity of Sound in Gases at High Temperatures, and the Ratio of the Specific Heats.—Prof. J. R. Partington: The Ratio of the Specific Heats of Air and of Carbon Dioxide.—Dr. A. B. Wood and Dr. F. B. Young: "Light Body" Hydrophones and the Directional Properties of Microphones.—Dr. A. B. Wood and Dr. F. B. Young: The Acoustic Disturbances produced by Small Bodies in Plane Waves transmitted through Water, with Special Reference to the Single Plate Direction Finder.—M. A. Giblett: Some Problems connected with Evaporation from Large Expanses of Water.—F. C. Toy: The Photographic Efficiency of Heterogeneous Light.

LINNEAN SOCIETY, at 5.—Dr. N. Annandale: The Vegetation of an Island in Chilka Lake on the East Coast of India, considered as a Preliminary to a Study of its Fauna.—Col. Godfery: The Fertilisation of Cephalanthera.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. F. L. Golla: The Objective Study of Neurosis (Croonian Lecture).

ROYAL SOCIETY OF MEDICINE (Dermatology Section), at 5.

CHEMICAL SOCIETY (at Institution of Mechanical Engineers), at 8.—Prof. B. Moore: The Natural Photo-synthetic Processes on Land and in Sea and Air, and their Relation to the Origin and Preservation of Life upon the Earth (Hugo Müller Lecture).

RÖNTGEN SOCIETY (at Royal Photographic Society), at 8.15.—Major G. W. C. Kaye and Others: Discussion on the Physics of the X-ray Tube.—Exhibition of Modern X-ray Tubes.—British Thomson-Houston Co., Ltd.: Demonstration of New Portable Coolidge Outfit.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.15.—Lecture.

ROYAL SOCIETY OF MEDICINE (General Meeting), at 8.30.—Sir Thomas Horder, Dr. G. C. Anderson, Mr. Clayton-Greene, W. S. Dickie, B. Harman, Dr. A. F. Hurst, Dr. Drury Pennington, Sir Humphry Rolleston, Dr. Gilbert Scott, and Dr. M. Wright: The Problem of the Private Clinic System in Great Britain.

FRIDAY, JUNE 17.

ROYAL ASTRONOMICAL SOCIETY, Geophysical Discussion, at 5.—Changes of Level in the British Isles, opened by H. L. P. Jolly, followed by Col. Sir C. F. Close and O. G. S. Crawford. Chairman: Col. Sir G. Lenox-Conyngham.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (Annual Meeting), at 8.15.—Major R. Knowles: The Mechanism and Treatment of Snake-bite in India.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 8.—J. C. Warburg: Foregrounds.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (at Kensington Town Hall), at 8.15.—Dr. C. Addison: The Part of the State in the Prevention of Disease (Cavendish Lecture).

ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Sir J. J. Thomson: Chemical Combination and the Structure of the Molecule.

MONDAY, JUNE 20.

ROYAL SOCIETY OF MEDICINE, at 5.—Special General Meeting.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—Dr. W. F. Hume: The Egyptian Wilderness.

TUESDAY, JUNE 21.

ROYAL HORTICULTURAL SOCIETY, at 3.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, at 5.—Dr. F. L. Golla: The Objective Study of Neurosis (Croonian Lecture).

ROYAL SOCIETY OF MEDICINE (General Meeting), at 5.

ROYAL STATISTICAL SOCIETY (at Surveyors' Institution), at 5.15.—Mrs. W. J. Barton: Women's Minimum Wages.

MINERALOGICAL SOCIETY (at Geological Society), at 5.30.—Prof. H. Hilton: Note on Crystal Measurement.—A. Brammall: Reconstruction Processes in Shales, Slates, and Phyllites.—A. Richardson: The Micro-petrography of the Rock-gypsum of Nottinghamshire.

WEDNESDAY, JUNE 22.

GEOLOGICAL SOCIETY OF LONDON, at 5.30.—F. Dixey: The Norite of Sierra Leone.—Dr. C. T. Trechmann and F. L. Spath: The Jurassic of New Zealand.

FARADAY SOCIETY (at Chemical Society), at 8.—C. J. Smithells: High Temperature Phenomena of Tungsten Filaments.—E. Hatschek: A Simple Apparatus for Determining the Coagulations Velocity of Gold Sols.—Prof. A. W. Porter: Variation of Surface Tension with Temperature.—S. M. Neale: The Influence of the Solvent upon Ionisation and the accompanying Heat Effect.—A. McKeown: The Potential of the Iodine Electrode and the Activity of the Iodine Ion at 25° C.—E. Kilburn Scott: Demonstration of the Transmission of Sounds by means of Rochelle Salt Crystals.

THURSDAY, JUNE 23.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Dr. E. F. Armstrong and T. P. Hilditch: A Study of Catalytic Actions at Solid Surfaces. VI. Surface Area and Specific Nature of a Catalyst: Two Independent Factors controlling the Resultant Activity.—Sir J. B. Henderson: A Contribution to the Thermodynamical Theory of Explosions, Part I.; and (with Prof. H. R. Hassé) Part II.—S. Butterworth: Eddy Current Losses in Cylindrical Conductors, with Special Applications to the Alternating-current Resistances of Short Coils.—E. S. Bieler: The Currents induced in a Cable by the Passage of a Mass of Magnetic Material over it.—Dr. G. Barlow and Dr. H. B. Keene: The Experimental Analysis of Sound in Air and Water: Some Experiments towards a Sound Spectrum.—Dr. G. Barlow: The Theory of Analysis of an Electric Current by Periodic Interruption.

FRIDAY, JUNE 24.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—S. Butterworth: Capacity and Eddy-current Effects in Inductometers.—Dr. E. Griffiths: New Specific Heat Apparatus.—Prof. A. O. Rankine: Encounters between Non-spherical Gas Molecules.—Dr. C. Chree: An Electro-culture Problem.

MONDAY, JUNE 27.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—K. Fry: The Dental Treatment of Congenital and Other Perforations of the Palate.

TUESDAY, JUNE 28.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—L. H. Dudley Buxton: The Ancient and Modern Inhabitants of Malta.

"Index-Numbers" and Wages-Regulation.

IF we want to study the movements of prices, whether within some more or less narrowly defined group of commodities (*e.g.* foodstuffs or textiles) or over a wider range (*e.g.* all the commoner commodities consumed in the United Kingdom), the necessity is soon felt for some means of summarising the diverse fluctuations noted. This can be readily effected by taking some particular price of each commodity as a standard (usually the price in a particular year or the average over a series of years), expressing the price of that commodity at any epoch as a percentage of the standard price—thus rendering the various movements comparable—and then averaging in some way for the whole series of commodities the *index-numbers* thus obtained. The average so calculated is usually itself termed an *index-number of prices*, with some qualifying expression to show to what it relates—*e.g.* an index-number of wholesale prices, of retail prices, or whatever it may be.

When consideration is given to the planning of such an (average) index-number, a great variety of questions at once arises. For example: (1) What commodities shall be included? (2) What sorts or qualities of each commodity? (3) What prices shall be used? Wholesale prices? Retail prices? Import values? Export values? At what markets? (4) How is the standard price for each commodity to be determined? For what reference year or reference period? (5) Finally, how are the individual index-numbers to be averaged? The answers to be given on these points evidently must depend on the question that the index-number is intended to answer. Only a definite question permits of a definite answer; and two very distinct questions have dominated researches into the movements of prices: (*a*) The question of the effect of currency changes—*e.g.* the substitution of paper for gold, or the varying supplies of the precious metals. (*b*) The question of changes in the "cost of living."

Questions of the first type present their own and numerous, difficulties; but from the point of view of practice there is one simplification, that the answer must be based on wholesale prices, quotations for which can be obtained with comparative ease. Such questions are certain to arise in a time following important new discoveries of the precious metals, as they did after the gold discoveries of 1848–49, which gave rise to two classical researches, those of William Newmarch and of Jevons.

Newmarch[1] used twenty-two quotations, no fewer than four of which were for cotton. 1845–50 was taken as the reference period. At first no summary was attempted; later the index-numbers for the individual commodities were simply added together instead of being averaged, so that the base-figure was 2200 instead of 100. Virtually, however, the index-number was the simple arithmetic mean of its components. This index-number has been given monthly in the *Economist* almost without a break since 1869, and remained on precisely the same basis until 1911. The inconvenience of the old basis had by this time become very marked—such vital commodities as foreign wheat, steel, petroleum, and rubber were not included—and the whole basis was revised. The number of quotations was raised from twenty-two to forty-four, and the base-period was altered from 1845–50 to 1901–5. When the simple arithmetic mean is used for the average the base-period is important, as it determines a virtual system of weighting.

The work of Jevons[2] (1863–65) is mainly of importance from his use of the geometric mean as the form of average. Without entering into the reasons that he assigned, some of which are obscure, one reason is clear and important. If the geometric mean be used, the ratio of the index-number for any year B to year A is the

[1] Cf. vols. v. and vi. of "The History of Prices," by Tooke and Newmarch; the Mercantile Reports by Newmarch in the Journal of the Royal Statistical Society, vols. xxii., xxiii., and xxiv.; and the volumes of the *Economist* from 1864. The summary figure appears to have been first given in 1869.

[2] Reprinted in "Investigations in Currency and Finance" (Macmillan, 1864).

same whatever year be used as base, and this is not the case if the arithmetic mean be used. Jevons's calculations were not maintained, but his work on this point of method has been fruitful.

Sauerbeck,[3] having regard to the unsatisfactory character of the old *Economist* number, constructed in 1886 a fresh index, using forty-five quotations. His base-period was the eleven years 1867–77, and he again used the simple arithmetic average for his mean. The calculation of the index-number was maintained, and it has now become the index-number of the *Statist*. In some ways this number also is no longer entirely satisfactory; foreign meat, for example, is not included, nor rubber.

The Board of Trade[4] in 1903 constructed an official index-number of wholesale prices in which a weighted arithmetic mean of the individual index-numbers was used, weights being given by the estimated values consumed. It was not a satisfactory number. The correct method of weighting does not seem to have been realised, and the weights actually used were based on a period different both from the reference year first employed (1871) and from that used later (1900), with the result that two widely divergent series of figures have been given. Very rightly the Board has decided that the old number should now be entirely dropped and a fresh index constructed on a new basis. This basis was fully described in a paper by Mr. A. W. Flux,[5] of the Board of Trade, read before the Royal Statistical Society for discussion in January last. So many as 150 quotations are used for the new number, and the geometric mean is employed, thus freeing the results from any influence of choice of reference period, and obtaining a completely consistent series of averages. No actual weights are used, but, as in the case of the *Economist* and the *Statist* index-numbers, there will be an approximate weighting by assigning more quotations to the more important commodities. It must be noted also that this number is really devised to answer a question different from that faced by Newmarch or Jevons—the effect, not of currency on prices, but of prices on currency. In the case of dutiable commodities the duty will therefore be included in the price; prices will not be quoted duty-free as in the case of the other wholesale numbers. The number, the first figures for which have been published in the *Board of Trade Journal*, represents a great advance.

All the above index-numbers are essentially index-numbers of wholesale prices, and deal preponderantly, though not wholly, with raw materials. Clearly this is not what is required for an index-number of "cost of living." But what do we mean by that very elastic phrase? As soon as we endeavour really to analyse the term, it becomes extraordinarily difficult to say. The clearest definition is "the cost of purchasing year by year the same schedule of commodities and services." It is nearly a century since Joseph Lowe[6] attempted calculations on this basis for the change in "cost of living" between 1792, 1813, and 1823 for a country labourer, a town mechanic, and a middle-class family, using estimated budgets of normal expenditure as his foundation. He also suggested the voluntary regulation of wages and salaries on such a basis.

It cannot be said that we have advanced much beyond this work of a century ago so far as regards method. The Board of Trade, soon after the beginning of the war, began the publication of an index-number of retail prices in the *Labour Gazette*, afterwards maintained by the Ministry of Labour. At first it was termed an index-number of "cost of living," but, very judiciously, that phrase was afterwards dropped, and it is now referred to only as a measure of changes in retail prices. It is to be regretted that not only members of the public, but also members of the Government themselves, still, nevertheless, continue to refer to it as an index of the "cost of living." The process of calculation was fully described in the *Labour Gazette* for March, 1920. A fixed schedule of foodstuffs was taken, based on the pre-war consumption of a working-class family, and the total cost of this schedule at the prices of the day compared with the prices of July, 1914, gives an index-number for food; index-numbers for working-class rents, clothing, fuel and light, and miscellanea (ironmongery, brushware, and pottery; soap and soda; tobacco and cigarettes; fares and newspapers) are determined by other inquiries, and these several group-indexes are combined into a general average on the basis of weights determined from pre-war expenditure.

The number is thus based entirely on the conception of purchasing a fixed schedule—the maintenance of a fixed mode of life. But when prices

[4] Report No. 321, 1903, and later *Labour Gazette* or "Annual Abstract of Labour Statistics."

[5] Journ. Stat. Soc., March, 1921. The paper has also been separately rinted.

[6] "The Present State of England" (London, 1822, and second edition, 1823).

change, people do not maintain their previous mode of life in absolute fixity, and in war-time they cannot do so. What, then, is to be done? The Committee[7] appointed in March, 1918, to report on "the actual increase since June, 1914, in the cost of living to the working classes," under the chairmanship of Lord Sumner, based its number on the actual *expenditure on living*—*i.e.* if a working-class family of definite size spent £x in the earlier year, and £y in the later year, the index-number of "cost of living" was taken as y/x. However interesting such a figure[8] may be—and it obviously has its interest—it is certainly not deserving of the title "an index-number of cost of living." To its use for regulating wages Labour leaders made the obvious objection: "If we can buy next to no food, you will say that we need have next to no wages." Had the Committee suggested (and the suggestion arises naturally out of its report) that, in the case of food, the Calorie-value of the dietary should be kept constant, this objection would have been obviated. If an index-number is to deserve the name of an index-number of cost of living at all, there must be fixity of a standard of some kind.

But the virulence of the discussion that has centred round the Ministry of Labour number is largely due to this fact, that it has been used as the basis of wages-regulation. Need a number for regulating wages (if they ought to be so regulated, which is itself a very debatable question) be a number for "cost of living"? For example, Customs and Excise duties certainly contribute to cost of living; but they are meant to be paid by those who choose to consume the dutiable commodities. Ought they, then, to be included, as duties are included in the Ministry of Labour number, in an index for regulating wages, thus merely shifting payment to the employer? Again, ought luxuries to be included? Neither tobacco nor newspapers can be called necessities. They are rightly included when it is a question of constructing an index-number of "cost of living." Ought they to be included in a number for wages-regulation, as in the Ministry of Labour number? These, and the like, are certainly questions that ought to be discussed, and if it is realised that the index-number is intended to serve the purpose of regulating wages, and not of indicating some vaguely conceived "cost of living," it may be possible to arrive at definite and agreed answers. The revision of the Ministry of Labour number will certainly have to be considered in the near future. Any revision should be carried out with a definite conception of the real end in view. If the Ministry of Labour would extend its views so far as to have some regard to working members of the community other than those who work with their hands for a weekly wage, it might consider the formation of a number more nearly related to the expenditure of the middle classes. No index-number of prices exists which forms any adequate basis for the regulation of salaries. Both the Ministry of Labour number and various wholesale numbers have, we believe, been used, but they are not satisfactory.

It is, in fact, time that the entire question of regulating wages and salaries in accordance with price movements, its justification, the formation of index-numbers for different classes of wage-earners (skilled and unskilled labour do not have the same budget; miners who get coal free and houses free ought not to have their wages affected by movements in rents and coal prices) and of salary-earners, and the relation that should subsist between a given movement in the index and the movement in the wage or salary should be fundamentally reconsidered.

[7] Cd. 8980, 1918. Cf. also Cd. 76, 1919, on "Cost of Living of Rural Workers," and the paper by Dr. A. L. Bowley on the measurement of changes in the cost of living, Journ. Stat. Soc., vol. lxxxii., 1919.

[8] Indexes of "expenditure on food" as against food prices were given for some time during the war in the *Labour Gazette*.

Psychology and Psychopathology.

(1) *Instinct and the Unconscious: A Contribution to a Biological Theory of the Psycho-Neuroses.* By Dr. W. H. R. Rivers. (The Cambridge Medical Series.) Pp. viii + 252. (Cambridge: At the University Press, 1920.) 16*s.* net.

(2) *Psychoanalysis: Its History, Theory, and Practice.* By André Tridon. Pp. xi + 272. (London: Kegan Paul, Trench, Trubner, and Co., Ltd., 1919.) 10*s.* 6*d.* net.

(1) THE investigations and theories of Freud have exerted a profound effect upon the development of psychology. This can be seen not only in the rapidly increasing body of teaching put forth by Freud and his orthodox followers, but still more in the mass of writings now appearing which are based largely on certain of Freud's fundamental doctrines, although they are developed along lines diverging widely from those accepted by the psychoanalyst.

In this latter group Dr. Rivers's work merits special attention, because, unlike so many of that prolific harvest of psychological and psychopatho-

logical books of which the war has sown the seed, it is not a mere *réchauffé* of other people's views, but the fruit of independent and efficient thought, and a solid attempt to advance scientific knowledge. The main portion of the book, comprising 158 pages, consists of a series of lectures delivered at Cambridge. The remaining pages contain reprints of papers written for various journals, which are related only indirectly to the consistent plan of development carried out in the lectures.

The author accepts in the main Freud's conception of the unconscious, and the "mechanisms" of conflict, repression, and so forth whereby Freud seeks to explain the processes occurring in consciousness, although considerable modifications in nomenclature and definition are introduced. He accepts also the view that the activities of consciousness are to be regarded as the resultant of various instinctive forces, but he develops this conception along lines which are partly akin to those worked out by McDougall, and partly the result of an independent mode of approach. The subject is regarded from a biological point of view, and the essential feature of the author's treatment is an attempt to bring the processes of consciousness, both in the normal and in the psychoneuroses, into relation with processes occurring at physiological levels, all being incorporated in a scheme of biological development. Thus suggestion, conflict, repression, and even such phenomena as sleep and hypnosis, are analysed into modes of reaction comparable with those discovered by Head and his fellow-workers to exist in physiological reflexes and in the mechanism of sensation. This view is extremely interesting and suggestive, though it may be doubted whether the relation is not one of analogy rather than of the identity which Dr. Rivers seems to postulate.

The same line of thought is carried on into the author's treatment of the psychoneuroses. Here, again, he accepts the main Freudian position that the psychoneuroses are due to conflicts occurring between the great instinctive forces of the mind, and that they are to be regarded biologically as attempts to find some solution of these conflicts. With regard to the nature of the instinctive forces concerned, however, he brings forward hypotheses which are open to considerable criticism. He suggests, for example, that hysteria is essentially dependent upon the activity of the danger-instincts, and implies that the type of hysteria met with in the war is the fundamental form of that disorder. This generalisation seems to be subject to the same accusation of narrowness and one-sidedness as has been levelled at the corresponding view of Freud that hysteria is essentially dependent upon the sex instincts, and it can scarcely have behind it the weight of clinical experience upon which the latter view was founded. It is to be remarked, moreover, that Dr. Rivers does not discuss the recent work of the Freud school on narcissism and the attempts which have been made to explain the war type of hysteria by means of this conception.

Another noteworthy omission is the absence of any reference to Trotter's views on herd-instinct, which surely ought at least to be considered in a work dealing with the fundamental reactions of the mind.

The papers forming the appendix are all of considerable interest, although, as has been said, they have only an indirect bearing on the main argument of the lectures. The book as a whole is, without doubt, one of the most important recent contributions to psychological literature.

(2) Dr. Tridon's book is of an altogether different type. It makes no claim to put forward any original line of thought, and its aim is best expressed in the author's own words as an attempt "to sum up in a concise form the views of the greatest American and foreign analysts." It includes a description not only of the doctrines of the orthodox Freud school, but also of those of Jung and Adler, who, although they originally worked with the Freud school, have now diverged from it to a very wide extent. To carry out such an aim within the limits of a small book is clearly a very difficult task, and Dr. Tridon will probably fail to satisfy the exponents of any of these divergent schools. He has, however, succeeded in producing a very readable and interesting book.

French Chemists and the Wa .

La Chimie et la Guerre, Science et Avenir. By Prof. Charles Moureu. ("Les Leçons de la Guerre.") Pp. iii+384. (Paris: Masson et Cie, 1920.) 10 francs net.

THE well-known publishing house of Masson et Cie, Paris, is issuing a series of volumes under the general title of "Les Leçons de la Guerre," with special reference to the experiences, circumstances, and prospects of France. The books which have already appeared deal with the military, naval, and aeronautical lessons of the war; with the effect of the war, immediate and prospective, on French industry; with alimentation and revictualling; and lastly with the influence of science, and particularly of chemistry, on the war, and, reciprocally,

with the influence of the war on the present condition and future development of that science. The volume under review is the work of Prof. C. Moureu, member of the Institute of France, professor of the Collège de France, president of the Chemical Society of France and of the International Union of Chemistry. No one is better fitted to expound the mutual relations of chemistry and war than Prof. Moureu, for no one during its course took a more active part in placing all the resources of that science at the disposal of his country. As is now well recognised, all the Allies vied with Germany in enlisting the services of their chemists in the prosecution of the war, and their united energy, resourcefulness, and skill eventually crushed their adversary. As the war was conducted, military valour, tenacity, and intelligent direction would not alone have decided the issue. Germany had imported a new element into the struggle which gave her an enormous initial advantage. The services of her great chemical manufacturing establishments had been deliberately and sedulously linked up for years previously with the war which was being prepared for in such a manner that, on its outbreak, all their appointments and machinery could at once be made available for its ruthless prosecution by every means which the diabolical ingenuity of their chemists could suggest.

April 22, 1915, which first saw the yellowish-green suffocating cloud of chlorine slowly wafted from the German trenches between Bixschoote and Langemark, is a black-letter day in the history of warfare. The infamous action of the Germans, done in cynical disregard of all international effort to mitigate the horrors of war, shocked the conscience of the civilised world. Whatever trace of knightly prowess or chivalry was left in modern war was thereby destroyed. To employ poisons against your enemy was the work of savages. What, it may be asked, was the ethical value of the boasted *Kultur* of a nation which could not only initiate, but also strive to develop and to intensify the evil of such agencies by all the means that its scientific knowledge and skill could suggest? The following table, taken from Prof. Moureu's book, giving a list of the chemical poisons, solid, liquid, and gaseous, which the Germans flung at their adversaries in the course of the war, requires no comment—at least to the organic chemist at all familiar with the noxious characters of such products. Their physiological action became only too well known by bitter experience.

Date when first used on the field of battle.	Name of substance.	Chemical formula.	Physiological action.
1915 April	Chlorine (gas)	Cl_2	Suffocating
June	Bromine (liquid)	Br_2	Suffocating
June	Benzylbromide (liquid)	$C_6H_5—CH_2Br$	Lachrymatory
July	Bromoacetone (liquid)	$CH_3—CO—CH_2Br$	Suffocating, lachrymatory
Aug.	Methyl chloro-sulphonate (liquid)	$SO_2\begin{cases} Cl \\ OCH_3 \end{cases}$	Suffocating
Aug.	Chloromethyl chloroformate (liquid)	$Cl—COOCH_2Cl$	Suffocating
Aug.	Bromomethyl ethylacetone (liquid)	$CH_3—CO—CHBr—CH_3$	Suffocating, lachrymatory
1916 July	Trichloromethyl chloroformate (liquid)	$Cl—COOCCl_3$	Suffocating
Dec.	Phosgene (gas)	$COCl_2$	Suffocating
1917 May	Chloropicrin (liquid)	CCl_3NO_2	Suffocating, lachrymatory
July	"Mustard gas" (ypérite) (liquid)	$S\begin{cases} CH_2.CH_2Cl \\ CH_2.CH_2Cl \end{cases}$	Suffocating, lachrymatory, vesicant
Sept.	Diphenylchloroarsine (solid)	$(C_6H_5)_2AsCl$	Suffocating, sternutatory
	Phenyldichloroarsine (liquid)	$C_6H_5AsCl_2$	
Sept.	Phenylcarbylamine chloride (liquid)	$C_6H_5N:C:Cl_2$	Nauseous and toxic
1918 April	Ethylarsine dichloride (liquid)	$C_2H_5AsCl_2$	Toxic, sternutatory
April	Ethylarsine dibromide (liquid)	$C_2H_5AsBr_2$	Toxic, sternutatory
June	Diphenylarsine cyanide (solid)	$(C_6H_5)_2AsCN$	Sternutatory
Sept.	N-Ethylcarbazol (solid)	$C_6H_4—C_6H_4$ \ / NC_2H_5	Sternutatory

Lord Kitchener at first refused to sanction reprisals of a like nature. But the French were prompt to meet the new danger. They realised that such reprisals were imperatively necessary in self-defence. Although, as was the case with all the Allies, France was totally unprepared for such savagery, before the end of April, 1915, she had organised means of protection and of counter-aggression in which the author of the book under review took a leading part.

Considerations of space preclude any detailed account of the way in which the dastardly action of the Germans was met and finally mastered. By the united efforts of the Allies, working in concert, the Germans were eventually taught a lesson which made their leaders bitterly regret that they had ever resorted to "poison gas" as an offensive

agent. It brought its own Nemesis by ultimately destroying the German *moral*.

The story of the organisation of the chemical and medical services of the war, as regards France, is the main theme of Prof. Moureu's book. He explains in detail how the whole procedure was gradually systematised. Nothing is more remarkable than the rapidity with which the chemical and medical strength of the nation was enlisted and co-ordinated. France is pre-eminently a logical nation, and her mental habitudes served her admirably, and, indeed, saved her in the crisis which had well-nigh overwhelmed her.

As regards her chemists, practically every name of note in the French chemical world is to be found in the lists furnished by Prof. Moureu. From first to last 268 French chemists were employed in the chemical services of the war. Thirteen of the laboratories in Paris were wholly concerned with the study of counter-aggressives alone. But the work of reprisals extended far beyond counter-aggressives. The services of the chemists were concerned with metallurgy, the production of alloys, the manufacture of explosives, aeronautics, camouflage, supply, sanitation, alimentation, medicaments, photographic chemicals, radio-active substances, and a host of minor matters, such as the recovery of solvents, optical glass, potash, platinum, etc. France, like this country, had gradually allowed Germany to obtain control of the manufacture of many articles as essential in war as in peace. Their production by the Allies had to be suddenly improvised. In some cases little or nothing was known concerning the details of their manufacture, and study and experiment were needed before their preparation on the large scale could be attempted.

But when the German onslaught had spent itself at the Marne France gained a breathing time, and she rapidly made up her leeway. Her success will permanently benefit her industry. She has consolidated the manufacture of certain articles for which, like us, she was formerly wholly dependent on Germany, and is now in a position to export them—a consummation which she owes, in great measure, to the patriotism and self-sacrifice of her chemists.

Prof. Moureu has conferred a benefit on his country by the compilation of this admirable work. The lessons it conveys are of profound importance to the national well-being. So far we have had nothing exactly like it in this country. But England has a no less thrilling story to tell. And it should be told quickly, lest we forget. Prof. Moureu's book affords an example of how to tell it.

T. E. THORPE.

Sport and Administration in Central Africa.

The Backbone of Africa: A Record of Travel during the Great War, with Some Suggestions for Administrative Reform. By Sir Alfred Sharpe. Pp. 232. (London: H. F. and G. Witherby, 1921.) 16*s*. net.

SIR ALFRED SHARPE first entered East Africa for the purpose of big-game shooting in about 1886. He was on long leave just then from a magistracy in Fiji. In 1887 he joined Lugard at the north end of Lake Nyasa, Lugard being engaged in a desperate fight with the Arab slave-traders established to the north-west of the Nyasa lake. In 1888 Sharpe was wounded in this bitter struggle, and in 1889 he returned and became a British Vice-Consul in that region. In 1891 he was made a Consul under the present writer's Commissionership, and served with him in what was then called "British Central Africa" until Johnston's transference to Tunis in 1897. Afterwards Sharpe became Governor of Nyasaland, and remained in that position until his retirement after the Coronation of King George in 1911. He was given a prominent part in the Coronation procession.

In 1912, unable to abate his interest in Africa, Sir Alfred Sharpe returned there as a private traveller and an adviser of highly placed trading companies. In this capacity, and still more as just one athirst for the solving of African secrets in fauna, flora, geography, and ethnology, he penetrated and repenetrated the eastern half of Africa from the southernmost parts of Portuguese East Africa to the Sudan and Egypt in the years between 1912 and 1917. He had hoped to serve strenuously in our wars with Germany during much of that period, but just because he so singularly knew East Africa, South-east Africa, Uganda, and Tanganyika, any British commission was withheld from him by Lord Kitchener; and his war service, for which he was recently rewarded, was with the Belgian armies. Since 1918 he has been making a special study of Liberia and contiguous regions in West Africa.

The book here reviewed is of great interest because it is so truthful. Sir Alfred Sharpe has no object to serve other than that of telling the truth about Africa, whether it suits one's theories or not. Whilst the material of the present work was being put together he was already lecturing to the Royal Geographical Society on Liberia, in the most forested part of West Africa.

For the naturalist, the best parts of the book under review are the statements about elephants (Sir Alfred, though never an offender against big-

game regulations, has discriminatingly shot elephants in Central, South-east, North Central, and West Africa), about a sub-fossil relic of the small forest elephants of West Central Africa, the tsetse-flies, the giant gorilla in the Lake Kivu region, and the vast herds of cattle to be found in Ruanda, a region which since the Great War has been handed over to Belgium to administer. The author thinks that the cattle in Ruanda—of an exaggerated straight-backed Indian type, with immense horns—must amount to two and a half millions. They die away (I might add) when brought down from the upland region to the countries of the tsetse-fly at lower levels. Unfortunately, the Watusi of Ruanda, once the "great" people of all that region and under other names of the lands between Tanganyika, Victoria and Albert Nyanzas, have become deplorably idle and wanton, and circumstances will oblige them to pull themselves together and reform.

H. H. Johnston.

Our Bookshelf.

The Modern Teacher: Essays on Educational Aims and Methods. Edited by A. Watson Bain. With an Introduction by Sir W. Henry Hadow. Pp. xv+272. (London: Methuen and Co., Ltd., 1921.) 10*s.* 6*d.* net.

This attractive volume contains ten essays, by writers of undoubted authority, on the chief subjects of school curricula, including civics, but excluding art and music. As each author has written independently of the others, there is a refreshing diversity in the modes of treatment. These vary from what is almost an apology by Mr. George Smith for the teaching of classics to Mr. A. W. Lucy's confident assurance, which allows him to plunge straight into practical details, in the case of mathematics. Even in defining the chief aims of education the essayists give conflicting opinions—which is all to the good, for it is when we think alike that we have ceased to think at all. In the section on science, for example, Mr. F. W. Sanderson reaffirms that it is the duty of education to "teach the average man the glory of his daily work and trade." The conspicuous success which has attended Mr. Sanderson's work at Oundle School makes his contribution to the volume a welcome one; the more so since, besides stating his ideals, he has indicated the lines along which they may be approached in practice.

The teacher who reads this book will not fail to find useful suggestions scattered about the more familiar paths of his knowledge; but probably its chief value for him will lie in the restoration of a true perspective, an appreciation of the complementary nature of the various branches of learning.

The Yearbook of the Universities of the Empire. 1921. Edited by W. H. Dawson. (Published for the Universities Bureau of the British Empire.) Pp. xiv+571. (London: G. Bell and Sons, Ltd., 1921.) 15*s.* net.

We are glad to be able to extend a welcome to the fifth edition of this useful volume. The plan adopted in the fourth edition of arranging the universities in groups—England, Wales, Scotland, Ireland, Canada, Australia, and so on—has been adhered to, and a brief introductory note precedes each group. A feature of the new edition is the numerous appendices, into which a vast amount of useful information has been incorporated. Short accounts are given of the institutes of accountants, architects, auctioneers, engineers, pharmaceutical chemists, and chartered secretaries, and of numerous other societies such as the Institute of Chemistry, the various colleges of physicians and surgeons of the United Kingdom, together with the regulations as to admission to these bodies. Particulars are also included of the matriculation examinations by joint boards and of inter-university scholarships, fellowships, etc. In Appendix xviii. an account is given of the conditions under which undergraduates and research students are admitted to foreign universities. The facilities for foreign students in most of the principal universities in America and in Europe, with the exception of the German and Austrian universities, are included in this section. The records are necessarily brief, but the information brought together is not readily available in any other single volume, and it makes the book invaluable as a work of reference.

Laboratory Manual of Organic Chemistry. By Dr. H. L. Fisher. Pp. x+331. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 12*s.* 6*d.* net.

Full experimental details and numerous practical hints which should be found very helpful form an unusual feature of manuals of practical organic chemistry. The theory of the preparations is not given, even in outline, but references to other textbooks are provided. This method does not seem likely to be so successful as that in which a brief but clear account of the reaction is given before the experiment is described. The section on organic analysis, which takes up 92 pages, is out of proportion, and far too detailed for a book of this kind.

Annual Reports on the Progress of Chemistry for 1920. Issued by the Chemical Society. Vol. xvii. Pp. x+264. (London: Gurney and Jackson, 1921.) 7*s* 6*d.* net.

The annual reports of the Chemical Society are valued as accurate and concise summaries of the main lines of advance in all branches of the pure science made during the year. The present volume maintains the high standard associated with previous issues.

Letters to the Editor.

The Constitution of Nickel.

My latest experiments have enabled me to obtain the mass spectrum of the element nickel by using the vapour of nickel carbonyl mixed with carbon dioxide. The ordinary discharge tube was employed to produce the positive rays, and difficulties of maintaining a steady discharge were overcome to some degree by the use of comparatively high pressure and a heavy current. The rays were analysed in the usual way by means of the mass spectrograph.

The spectrum consists of two lines, the stronger at 58 and the weaker at 60. They are most conveniently placed between the mercury groups of the third and fourth order, with which they can be compared with an accuracy of 1/10th per cent. The results were also checked by comparison with the CO_2 line 44, and appear to be integral within the above error. Nickel therefore consists of at least two isotopes. The intensities of the lines are about in the ratio 2 : 1, and this agrees with the accepted atomic weight 58·68.

F. W. Aston.

Cavendish Laboratory, Cambridge, June 10.

A Novel Magneto-Optical Effect.

Early in April last, while my son, Malcolm Thomson, was operating, in a building of the River Works plant of the General Electric Co., a resistance welder for closing the seams of steel Langmuir mercury vacuum pumps, in which work the current is applied and cut off at about one-half second intervals, there was noticed by one of the working force, Mr. Davis, who happened to be favourably located, a peculiar intermittent illumination of the space near the welder as the current went on and off. My son at once placed himself in a similar position and saw the novel effect, and noted a number of conditions accompanying it, perhaps the most important being that a single-turn loop from the welding transformer to the work and back was carrying about 7000 amperes, and that the luminous effect was spread in the space in which would be located the magnetic field from this loop; that the sunlight was entering the building through high windows and shining across the space in which the field was produced at intervals; that the effect was most conspicuous when one looked towards the shadows and across the sunbeams, and also across the magnetic field.

This would be expressed by saying that the best effect was observed when the line of vision was downward at an angle intersecting the entering sunbeams, and into the shadows under the beam furnished fortunately by a partition a few feet high, over which the sunlight came. The magnetic field, neglecting the curvature of the lines, was, generally speaking, at right angles to the line of sight and to the direction of the sunlight. My son also noticed that the effect of increased luminosity was coincident with the putting on of the current, and disappeared at once on cutting off the field. It was thus clear that it depended on the establishment of the magnetic field. He reported these facts to me, and they were confirmed by me. Other observers were soon enlisted, and on several favourable sunny days all the above observations were confirmed by them. Further, my son had not been able to see any effect when looking across the sunbeam from the opposite side. This means that, with the sunbeams streaming in from the south, the effect was observed looking southward and downward, the windows admitting the light being to the south. Looking from the south across the beam gave no result, though it was not possible to look directly across the beam on a slant upward into any dark shadows and at the same time have the line of vision cross the magnetic field.

It is interesting to note at this point that the luminosity filled the whole space, and extended as far away as four feet or more from the magnetic loop, and that it was not especially noted as more intense near the loop than at a distance therefrom of, say, two feet or more.

Mr. Malcolm Thomson had further observed that by cutting out the loop from the secondary terminals (clamps) of the welding transformer, and simply joining those terminals by an iron bar, as is done in resistance welding, the luminous effect in the neighbourhood of the transformer was still visible, but was much more feeble than when the heavy loop was used. It occurred to me to examine the light by a large Nicol's prism. It was found that there was a distinct polarisation of the light from the space. This means that when the magnetic field was on the sunlight was scattered in the direction of the observer from the space occupied by the sunlight beam and the magnetic field, and that such scattered or deflected light was polarised.

It occurred to me, as a possible factor in the case, that as the building was used in part to carry on arc welding by iron arcs there might be suspended in the air of the building iron particles or finely divided oxides or compounds of iron which in some way were oriented by the magnetic field, resulting in the scattered light noted. This was confirmed in part by making the test observations when the large doors of the building had been open for some hours. The effect was present, though difficult to detect. This led to the suggestion to bring an iron arc into operation near the space in which the luminous effect had been seen. This was done, and with an enhancement of the effect.

At this stage the further observations were carried on in the Thomson Laboratory at Lynn, Mass., with the aid of the laboratory staff (A. L. Ellis, H. L. Watson, Dr. Hollnagel, and others).

Two sets of test apparatus were prepared at my suggestion. One large welding transformer was mounted in a special room, into which the sunbeams could be received in the afternoon as the windows faced south by west. The secondary terminals were joined by a large loop of heavy copper cable (about 12 sq. cm. section) of a loop diameter of 0·6 m. The loop consisted of two turns. The plane of the loop was vertical and was nearly north and south, or in a plane parallel to the direction of the entering sunbeams, so that the magnetic field would be in the main horizontal and transverse to the light of the sun entering downward as before. An iron arc was arranged to be operated so that the smoke from it would rise from below and enter the field of the loop, and by changing the relative position of the arc the smoke column, widening as it rose, could be made to bathe the turns of the coil, cross its axis, or, at a distance away, merely enter the field. As the experiments thus far had always involved connection to the shop plant, with 60-cycle alternating current, a check apparatus was set up, consisting of a storage battery (of a type such as is used in automobile

starting) arranged on a stand. In circuit with it, and under control of a switch, was a coil of about 0·2 m. diameter, and giving a field due to about 2500 ampere turns when the switch was closed. This second apparatus could be moved about, and was entirely independent of supply circuits or static disturbances which might be present in them.

The first tests were made with the transformer loop (representing a field of 20,000 ampere turns), and were very striking. The rising smoke from the small iron arc, only moderately visible in the sunbeam, became decidedly luminous when the field was put on. Each closure of the current switch to the primary of the transformer was instantly followed by the brilliant smoke effect, and the effect instantly disappeared on the opening. A black background had been provided in front of which the smoke rose. After the arc had been running a few minutes only it was seen that the air of the room was carrying sufficient of the smoke particles to give the effect anywhere in the space covered by the magnetic field and the sunbeams, even a number of feet away from the coil. In this case the appearance was as if in the air there were diffused some substance or material which became visible only in the combined sunlight and magnetic field. That in this case the luminous effect is not greater near the coil loop than some feet away indicates that orientation, or whatever causes the effect, is complete even in a rather weak field. Thorough ventilation of the room by opening windows caused the effect to fade out gradually by removal of the active particles.

The experiments with direct-current coil and battery conclusively showed that the effect was present with it as with alternating current, and incidentally established the fact that the effect on the particles is independent of the direction of magnetisation. It is doubtful if high-frequency tests would allow us to discover whether the establishment of the effect requires time. Probably not. Observations made through the axis of the loop of two turns show a minimum of effect, from which it may be inferred that it is not present if the viewing is exactly along the field-line direction.

Polarisation.—Having obtained, as described in the foregoing, a controllable and relatively brilliant source of the luminosity, tests with the Nicol's prism were resumed. It was soon noted that the polarisation was decided as controlled by the magnetic field. Moreover, the very curious fact was discovered by me, that the fumes from the iron arc were composite so far as analysis by the polarising prism was concerned. The bluish-coloured smoke arising gave but little effect, but there was with it a yellowish-grey fume, which was highly luminous in one position of viewing by the prism, and invisible when the prism was at right angles to that position. This indicates complete polarisation when the field is on for the light diffused from the particles in the yellowish-grey fumes. This is an extraordinary effect for which no explanation suggests itself, for the field lines are not straight, but wrap themselves around the coil or loop in curved directions, and the effect is apparently complete even with the fumes rising in the space where the lines are strongly curved.

It remains to use a vertical beam of light and make tests from opposite directions across the field, also to use artificial light instead of sunlight. It would seem possible to design a small demonstration apparatus consisting of a coil to be put on a battery or lighting circuit, A.C. or D.C., a small iron arc between two wires, a box with darkened interior to be filled with fumes, having two sides of glass, one for the admission of the light beam and the other a window at right angles for observation. Two coils placed outside the box space and opposite each other, or capable of application in different relations, would have advantages. Eye shields to cut out extraneous light and a tortuous chimney conveying the smoke, but cutting off the light from the iron arc, are desirable additions to the equipment, as also an analyser as part of the apparatus for the polarisation effect.

The Microscope.—Attempts have been made to catch the particles in the smoke from the arc upon a glass slide for microscopic examination as to their form under high powers. That they are exceedingly fine is evident from their remaining in suspension so long in the air and diffusing themselves rapidly through the air. That an exceedingly small amount of material suffices for making the whole air of a large room capable of showing the effect is evident also. The sunbeam may enter the room, and its course is not disclosed by them unless the magnetic field exists. It seems natural to suppose that the particles consist of some form of iron or iron oxide, but without proof this cannot be fully decided. Other particles might exist, giving such an effect, but it must be confessed this does not seem probable. Other fumes and smoke from arcs so far have given no results. The smoke from a nickel arc does not give the effect. Whether a cobalt arc will yield fumes behaving like iron smoke is not yet known.

The fumes and smoke of an iron arc were caught on a clean microscope slide until a patch of sediment of a slightly yellowish-brown tint, but very pale, was deposited. Under moderate powers very little of any definiteness is shown, but under the high power of an oil-immersion lens of about $1\frac{1}{2}$ mm. focal length there is disclosed a curious structure of particles seemingly between 0·0002 and 0·0001 mm. diameter, which particles are frequently strung together, 4, 5, 6, or more, in a line, giving the effect of a short piece of chain made of small roundish particles, slightly spaced apart, or of a short section of a string of beads (round beads) not touching one another. Many of these structures appear to be straight, and some are curved. Evidently in a magnetic field these chains of particles, presumably of oxide of iron and magnetic, would line up and reflect or diffuse light of the sun striking them. If the direction of vision was such as to favour polarisation of the rays in a direction nearly at right angles to the incidence of the solar beam the polariscope effect would be accounted for measurably. Apart from polarisation, the lining up of the chains would also account for the extra *visibility* of the smoke under the conditions of the experiment.

It would seem from the foregoing that a considerable length of column of smoke from the iron arc, subjected transversely to a magnetic field, might be expected to act as a means of obtaining polarised light in the direction of the beam itself. This assumes that there will be a considerable scattering of light polarised as above described in a direction sidewise, leaving the light which passes through polarised in a plane at right angles. The apparatus might be compared in its action to a Nicol's prism, transmitting rays in one plane and throwing out laterally those in the other. This suggestion will be tested as soon as proper arrangements can be made.

The polarised light which is sent out from the smoke particles in a direction transverse to the sunlight beams, when the magnetic field is put on, is in the same plane as that reflected from a sheet of glass at the polarising angle receiving the same beam. This fact is in accordance with what might be ex-

pected if the short sections of chain or beaded particles were oriented or lined up by the magnetic field; the transverse waves of light vibrating in a plane intersecting the length of the chains would not be deflected on account of the extremely small diameter of the particles composing them, but waves vibrating in the plane of the length of the chains would be reflected to the side, and this would account for their plane of polarisation being what it is. Such waves would behave as if reflected from short rods in line with the plane of vibration, while the extremely small diameter of the rods would not sufficiently intercept the light vibrating in a plane transverse to their length.

The continuation of the investigation with artificial light and other varied conditions is anticipated.

ELIHU THOMSON.

Thomson Laboratory of General Electric Co., Lynn, Mass., May 23.

Geometrical Isomerism in Monomolecular Films.

IN the course of investigations on these films by a method differing only in details from that described by Langmuir (Journ. Amer. Chem. Soc., 1917, p. 1868) I have found striking differences between the properties of films formed from the "cis" and "trans" forms of some fatty acids containing an ethylenic linkage, which indicate that of the two pairs of acids, oleic and elaidic, erucic and brassidic, oleic and erucic are the "cis" forms and elaidic and brassidic the "trans." The results appear to be consistent with Langmuir's conception of the structure of the films, and this stereochemical configuration is that usually regarded as correct from chemical considerations.

According to the theory, the films are one molecule in thickness. With saturated acids, such as palmitic, the molecules are attracted to the water by the

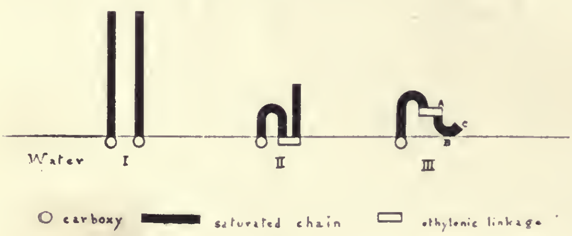

FIG. 1.

carboxyl groups, and are arranged as in Fig. 1, I. Unsaturated acids are also attracted by their ethylenic linkages, and when, as in the acids mentioned, these are approximately in the middle of the chains, the molecules in the film will take up the position in Fig. 1, II. or III. The attraction of the double bond for water is less powerful than that of the carboxyl, and when a lateral compression is applied to the film the area per molecule will diminish by some or all of the molecules straightening out to the position I.

Fig. 1 shows that a difference is to be expected between the "cis" and "trans" isomers. The double bond in the "cis" form can approach as closely as desired to the water, but in the "trans" form *the saturated portion of the chain ABC must be forced in among the water molecules.* Although it is known from stereochemical considerations that a hydrocarbon chain is flexible, yet its radius of curvature cannot be reduced below that of a ring of five carbon atoms without encountering resistance; there will, therefore, probably be a considerably greater resistance to the approach of the double bond to the water in the case of the "trans" form than in the case of the "cis."

The results obtained point clearly, I think, to a greater tendency to occupy the larger area with oleic than with elaidic acid, and a larger with erucic than with brassidic acid. Oleic acid, when first put on distilled water and a compression of about 1·4 dynes per cm. applied to the film, occupies about 46×10^{-16} sq. cm. per molecule; the area decreases steadily with time, however. Elaidic acid occupies about 30 units of area at the earliest moment when readings can be taken, and the area diminishes rapidly to about 22 units, when the film behaves like one of palmitic acid.

In the 22-carbon series there appears to be a smaller tendency than in the 18-carbon series for the double bond to approach the water. Erucic acid gives films rather similar to elaidic acid, but brassidic acid occupies the greater area for so short a time that the curves of compression of the films are not very different from those of a saturated acid such as palmitic.

It is hoped to amplify these experiments and publish full details later.

Trinity College, Cambridge, May 28.

Sources and Sinks.

LORD KELVIN in a paper "On the Forces Experienced by Solids Immersed in a Moving Liquid" (Proc. Roy. Soc. Edin., 1870) compared two tubes, with liquid flowing through each, with two hard steel magnets and stated that the forces are opposite in the two cases; unlike poles attracting and like poles repelling in the magnetic system, while in the hydrokinetic there is attraction between like ends and repulsion between unlike.

That two sources of like sign attract and two of unlike sign repel, as here stated, is generally accepted. An examination, however, of the case of a source and an equal sink appears to contradict this. When source and sink coincide the fluid medium is at rest, but when they are separated it is in motion and possesses kinetic energy. Work, therefore, must be done to effect the separation. This suggests that the force between source and sink is one of attraction. That this is actually the case is shown by the following experiment.

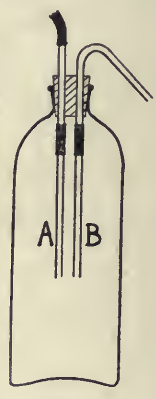

FIG. 1.

Two glass tubes A and B (Fig. 1) are connected by short lengths of rubber tubing to short tubes, which pass about 1 cm. apart through a cork in the neck of a Winchester bottle full of water. The tube A is connected to a water-supply and its open end constitutes an experimental source. The end of the tube B is an equal sink. The source and sink attract smartly and the ends of the tubes remain in contact so long as the water flows.

A. F. DUFTON.

Polarisation Phenomena in an X-ray Bulb.

HITHERTO the potential difference required to produce a discharge through a well-exhausted vacuum tube has been considered to vary only with the pressure of the gas. In the course, however, of some experiments with an X-ray bulb (where the pressure

could be regulated by a Gaede pump and measured by a McLeod gauge) a continuous discharge was maintained for about eight hours on several consecutive days, and I have observed a gradual hardening in spite of the maintenance of a comparatively high pressure. Further experiments carried out in this direction have revealed a remarkable effect which takes place in an X-ray bulb or, more generally, in any vacuum tube after a sufficiently long and continuous run—an effect similar to the polarisation of an electrolytic cell. This is, that after the discharge has been kept running for a sufficiently long time through a tube (inside which the pressure is kept nearly constant) a time arrives when the current flowing through the tube begins to decrease, and finally ceases altogether. To continue the discharge it is then necessary to increase either the potential difference applied to the electrodes or the pressure inside the tube. By repeating this operation several times I could ultimately reach a stage where a potential difference of more than 50,000 volts was not sufficient to produce a discharge in the bulb, although the pressure was as high as 0·060 mm., whereas under ordinary conditions in the same bulb a much smaller potential difference was sufficient to produce a discharge under a pressure of the order of 0·001 mm. After the discharge has been stopped the bulb gradually returns to its normal condition, but afterwards a comparatively short run is sufficient to bring the bulb back to the state of polarisation.

It could be further shown that the effect is not due to changes in the nature of the gas in the bulb brought about by the discharge. A large side-tube containing two electrodes, the shape and distance apart of which were essentially the same as in the X-ray bulb, was fused into it. When after a long run the main bulb became polarised, so that the highest available voltage could not break down its resistance in spite of a high pressure of about 1/20 mm., a potential difference of 1200 volts, supplied by a battery of small cells, when put across the side-tube was found to produce a normal discharge.

Experiments, which will be described elsewhere, give some evidence in support of the view that this effect is due to the destruction by the discharge of the gaseous layer on the surface of the electrodes.

It seems probable that the hardening of an X-ray bulb with usage is due not only to the disappearance of the gas in the bulb, but also to the phenomenon described in this letter. S. RATNER.

The Physical Laboratory, Victoria University, Manchester, June 1.

Observations of Plant-growth with the Recording Ultramicrometer.

AT the meeting of the Royal Dublin Society on January 25 last, as reported in NATURE for February 24, p. 850, I described a form of ultramicrometer in which the minute movement of one plate of a parallel plate condenser, forming part of a thermionic-valve oscillating circuit, is recorded by a galvanometer. We are now applying this apparatus to the study of plant-growth, and as some of the preliminary observations show very clearly the pulsations of growth described by Sir J. C. Bose, it may be of interest to give a short account of these results.

In applying the method to this problem the upper plate of the condenser is a thin aluminium disc, about 6 cm. in diameter, supported by a long flat strip of spring steel, so as to be situated about 1/10 mm. above the lower fixed (horizontal) plate. The latter plate may be given small vertical movements by means of a micrometer screw for adjustment or calibration of the apparatus. In many of our observations the apparatus is adjusted to give 150 divisions on the galvanometer scale for a displacement of the upper plate through 1/1000 cm., but it can be made many times more or less sensitive simply by altering the galvanometer shunt.

To the recording (upper) plate is rigidly attached a short wooden arm against which the plant member presses lightly. It is found that a weight of 1/10 gram placed on this causes a galvanometer deflection of 100 divisions. This indicates the order of magnitude of the stress on the plant under observation. During experiments on roots the root-tip presses

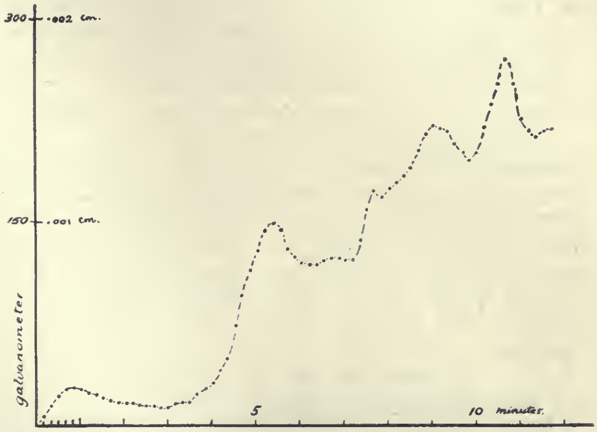

FIG. 1.—Broad bean root-shoot (four days old).

the plate downwards; in other cases the movement is upwards.

As an example of one type of record obtained the accompanying curve is appended. It represents the (downward) growth of the root-shoot of a broad-bean which had been planted some four days before and had just been removed from the ground. A considerable time had been allowed to elapse after placing the plant in position before observations were commenced.

I have to thank two botanical students, Miss Cannon and Mr. Saunders, for the part they are taking in the work. JOHN J. DOWLING.

Department of Physics, University College, Dublin.

Cup and Ring Markings.

REFERRING to the note anent the above which appeared in NATURE of June 9, p. 468, may I mention that these peculiar surface-features can frequently be seen upon old mortar, stucco, and calcareous sandstones, and that they are due to molecular re-arrangement of the calcium carbonate, and not to any artistic efforts on the part of prehistoric man, as is frequently supposed?

At the Royal Society in 1896 I exhibited photographs of some remarkable examples of "cup and ring markings" which had developed on the stucco of one of the houses in Warrior Square, St. Leonards-on-Sea. Similar "patterns" may sometimes be seen on old "American cloth" which has been subjected to tension, and also on old oil paintings. In these cases the gradual shrinkage of the canvas backing has produced the effect by causing lines of fracture in the more homogeneous layers of paint.

June 11. C. CARUS-WILSON.

Some War Developments of Explosives.[1]

By SIR ROBERT ROBERTSON, K.B.E., F.R.S.

IT is not proposed to describe the great factories that arose during the war for the manufacture of explosives, but to indicate by one or two examples some of the conditions which led to developments.

PRODUCTION.

The enormous weekly production was reached of 1500 tons of trinitrotoluene, 300 tons of picric acid, 3000 tons of ammonium nitrate, and 2000 tons of cordite. To produce these were required such weekly quantities as the following: 6600 tons of pyrites, or 2700 tons of sulphur, 8300 tons of Chile saltpetre, 720 tons of toluene (from 600,000 tons of coal), 162 tons of phenol (which would have required 1,000,000 tons of coal, if synthetic production had not been established), 700 tons of ammonia (from 250,000 tons of coal), 374 tons of glycerine (from 2700 tons of fat), 700 tons of cotton cellulose (from 1060 tons of wastes), and 1200 tons of alcohol and ether (from 4200 tons of grain).

These numbers indicate not only the magnitude of the production, but also the interdependence of a large number of industrial chemical activities, and, although many of the products were derived from our own coal, it brings home the dependence of the country on overseas transport of many of the essential substances, such as pyrites, sulphur, Chile nitrate, and cotton.

FIRING AND DETONATION OF A SHELL.

The Propellant.—The processes for the manufacture of cordite and of its ingredients had been the subject of study, and considerable advances had been made, so that it might fairly be claimed that this country led the way in the technique and safety precautions involved in the manufacture of propellants. The existing factories were also capable of extension, until the demand became so great that additional ones had to be erected.

At first, the propellant used was cordite M.D., composed of nitroglycerine, guncotton, and mineral jelly, in which acetone was used to gelatinise the guncotton. A nitrocellulose powder obtained from America was also used. The demand for propellant to be made in this country ultimately reached 1500 tons a week, and this, even with an efficient system of acetone recovery, would have involved an expenditure of that solvent of above 400 tons a week. On account of the shortage of supply of this solvent, a new propellant for the Land Service was introduced—cordite R.D.B.—in which ether-alcohol was substituted for acetone as a solvent, a change necessitating the choice of a nitrocellulose of a lower degree of nitration than guncotton, and alterations in the proportions of the other ingredients. For the new propellant the conditions were laid down and met that it should have the same heat energy, that it should give the same ballistics as cordite M.D., in order to avoid alteration in calculating ranges from data obtained with the older propellant, and that it should be capable of being manufactured by the machinery available and with the technique of manufacture known in the country.

The main changes introduced were in the manufacture of the nitrocellulose and in the supply of the solvent. As ether-alcohol is a less powerful solvent than acetone, even for the special nitrocellulose employed, a strict definition of the nitrocellulose was necessary, and the necessity to provide this in suitable form led to much investigative work on the nature of the cellulose, with the result that its manufacture was brought under a system of strict chemical control. This control had among its objects the elimination of ligneous impurities and the standardisation of the viscosity of the cellulose, since if its viscosity were uniform and low, it was found that the gelatinisation of the nitrocellulose when incorporated with the nitroglycerine and mineral jelly was greatly facilitated, and the production of uniform cords assisted. Ligneous matter in the cellulose was rendered visible by a process in which the woody matter was selectively dyed, and the viscosity of the cellulose was measured by the rate of fall of a steel sphere falling through a solution of cellulose.

The supply of alcohol was obtained entirely from the distilleries of this country, and a large plant for converting a portion of it into ether was erected at Gretna. Nearly 1000 tons of alcohol, or the equivalent of about 200,000 gallons of proof spirit, were required for the production of the 1500 tons of R.D.B. cordite a week, and this requirement it was which led to the restricted sale and increased cost of whisky.

THE HIGH EXPLOSIVE SHELL.

Prior to the war the Land Service used for the most part shrapnel shell, designed to project a shower of lead bullets, efficacious against *personnel*, but of little value in attacking fortified positions, for which high explosive shell are required.

Shrapnel was very largely used by the Land Service throughout the war, but the earlier type of high explosive shell filled with lyddite (picric acid), and brought to explosion by the ignition of a fiercely burning mixture, was abandoned for one in which true detonation was secured with certainty. The latest type of high explosive shell was exemplified by a 4·5-in. howitzer shell fitted with a graze fuze (Fig. 1).

The Fuze.—A graze fuze is a mechanism which gives rise to a flash when the shell grazes on

[1] Summary of a Friday evening discourse delivered at the Royal Institution on May 6.

the ground. It must be capable of being handled roughly without firing, and must not act when the considerable forces involved in firing it from a gun are impressed upon it and upon all its parts. The magnitude of these forces is illustrated by the fact that a fuze weighing $2\frac{1}{2}$ lb. when fired from an eighteen-pounder gun weighs about 11 tons—the stress corresponding to 15,000 times the acceleration due to gravity. These forces are taken advantage of to render the fuze "live"—that is, to put it into a condition when it will act on the slightest provocation.

In the interior of the fuze is a brass cylinder with an axial hole, on the top of which is placed a capsule containing a highly sensitive flash composition. To prevent this cylinder from moving forward in handling, a bolt lies athwart its top edge, and this bolt is retained in this position by a small pin placed vertically at the back of the bolt and having its base pressed upward by a spring working in a vertical cylindrical cavity. On firing, this pin, weighing 1·3 grams, is acted on by a force equivalent to 20 kg., overcomes the resistance of its spring, and recedes into its cavity. The force due to the shell's rotation causes the bolt to fly outwards, thus freeing the brass cylinder, which now is prevented from moving forward on to a needle only by the interposition of a light spring. The fuze is now "live," and on the slightest check being given to the forward movement of the shell, as, for example, by grazing on soft earth, the cylinder moves forward by its own inertia on to the needle, which pricks the capsule, causing a jet of flame to pass down the centre of the fuze. The object of all this mechanism is to supply at the proper time a flash for operating the next member, the gaine, where it gives rise to a detonation.

The Gaine.—This is a tube (from French *gaine*, a sheath) with steel walls of quarter-inch annulus. In its upper portion is a pellet of gunpowder which is ignited by the flash from the fuze, and sends a larger flash on to an open capsule containing fulminate of mercury situated over pellets of tetryl. The fulminate detonates, and in turn causes the tetryl to detonate, and to deliver from the bottom end of the gaine a very intense blow to a series of explosive intermediaries which communicate the detonation to the main bursting charge.

Intermediaries.—The first of these is a bag of T.N.T. crystals situated in a thin steel container tube which encloses it and the gaine. This T.N.T., on detonation, brings to detonation an annular layer of T.N.T. cast round the container, and this in turn brings about the detonation of the main charge of the shell. The train of detonation is thus somewhat complicated, and in its evolution many important principles had to be observed.

Sensitiveness and Violence.—Thus the sensitiveness of the various explosives used had to be determined, since, on account of the magnitude of the acceleration imparted to all parts of the shell on firing it from a gun, a column of a sensitive explosive over a certain length and weight will be liable to detonate on account of the sudden force applied. In proportion to their sensitiveness to mechanical shock, therefore, explosives in shell must be graduated in regard to length of column employed. A general principle is to have next to the detonator a somewhat sensitive explosive, and to reinforce the impulse derived from it by one less sensitive, but still delivering an intense blow. It is important, therefore, to have quantitative values for the sensitiveness of explosives to mechanical shock, and some of the values thus obtained are given in the following table:—

	Figure of insensitiveness (Picric acid=100)
Mercury fulminate	10
Nitroglycerine	13
Dry guncotton	23
Tetryl	70
Tetranitroaniline	86
Picric acid	100
Trinitrotoluene	115
Amatol 80/20	120

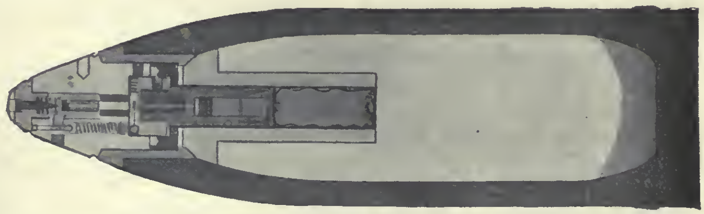

FIG. 1.

It is important also to know the violence of the various explosives used, both by themselves and also when assembled in the various components, and it was in this connection that the principle of the pressure bar, enunciated by the late Prof. Bertram Hopkinson in a discourse to the Royal Institution in January of 1912, was of the greatest value. This depends on the experimental resolution of the momentum of the blow into pressure and time. When a charge is fired against the end of a cylindrical steel bar ballistically suspended, a wave of compression travels along the bar and is reflected at the far end as a wave of tension. To investigate the properties of the wave, a short length of the end of the bar farthest from the end to which the blow is delivered is cut off and the faces are surfaced, the short piece (known as the time-piece) being caused to adhere closely to the bar, usually by a film of vaseline. The compression wave travels unchanged through the joint into the time-piece, but the reflected tension cannot pass through it. Hence when the amplitude of the reflected tension wave reaching the joint becomes greater than that of the oncoming compression wave, the time-piece is projected from the shaft with a momentum which depends on the pressure exerted by the explosive

and the time taken by the wave to traverse the length of the time-piece. This momentum is measured by catching the time-piece in a ballistic pendulum, and, the velocity of the propagation of the wave through steel being known, the mean pressure exerted during an extremely small time interval can be calculated.

(One of the instruments for determining the pressure developed by a detonator was shown, and a detonator fired, the mark drawn by the swing of the pendulum which caught the time-piece being shown on the screen.)

The application of this apparatus not only gave important information as to the limiting quantity of fulminate necessary to bring about complete detonation of the tetryl and as to the effect of the thickness of the wall of the gaine, but it also emphasised the necessity for avoiding gaps in the train of detonation on account of the very rapid falling off in violence of the blow when even a small air-gap is introduced.

Main Filling.—It was early recognised that the supply of picric acid and T.N.T. by itself would be quite insufficient. It was at this point that the late Lord Moulton took steps to secure supplies of essential explosives and their ingredients, with such success that the supply of explosives in no long time came to be ahead of the demand. But even when a method for the production of T.N.T. had been worked out, and its supply on a fairly large scale was in prospect, it was apparent that the demand for high explosive was such that it could not be met by the supplies of nitro-compounds in sight.

Experiments were then made to test the capabilities of mixtures of ammonium nitrate and trinitrotoluene for shell filling, and these gave much promise from the start. They were found to possess the requisite degree of inertness and insensitiveness to enable them to withstand set-back on firing from a gun, to have a high rate of detonation, and when detonated in a shell, as was done first in March, 1915, to give evidence of the required violence necessary to fragment the shell.

The first mixture (later termed amatol 40/60, these being the proportions of ammonium nitrate to T.N.T.) was capable of being poured as a thick porridge into shell, and so presented few difficulties for large-scale production. This was at once followed up by similar experiments with a still greater proportion of ammonium nitrate, up to that which is practically the theoretical one for complete combustion of all the carbon of the trinitrotoluene to carbon dioxide, and of all the hydrogen in both substances to water. This explosive, amatol 80/20, was fired in a shell in April, 1915, and gave excellent results. Its explosive properties, as regards insensitiveness, stability, and tests for power, were satisfactory, and it was almost immediately approved as a Service explosive.

Amatol 80/20.—The development of amatol 80/20 was slower. Prepared originally on the large scale by bringing together the finely powdered ingredients in a mixing machine, or by grinding them under edge-runners, 80/20 amatol was ultimately most readily produced by taking advantage of the plasticity of the heated mixture due to the trinitrotoluene melting. Hydraulic presses were used for introducing the powdered or ground explosive into shell; for the plastic 80/20, a worm feed was found expeditious and rapid.

In the course of the manufacture of the enormous quantities of these substances many points of interest and of difficulty arose, which were solved by the assistance of more and more scientific investigators.

The following tables give some data on the explosive properties of the amatols in comparison with some other explosives:—

Heat of Detonation and Gases Evolved.

	Calories per gram (water gaseous)	Total gases c.c. per gram
Picric acid ...	914	744
Trinitrotoluene	924	728
Amatol 40/60 ...	920	892
Amatol 80/20 ...	1004	907
Tetryl	1090	794
Guncotton ...	892	875
Nitroglycerine	1478	713

Rates of Detonation.

	Density of loading	Metres per second
Nitroglycerine ...	(Liquid)	8000
Tetryl	1·63	7520
Guncotton (dry) ...	1·20	7300
Picric acid	1·63	7250
Trinitrotoluene ...	1·57	6950
Amatol 40/60 ...	1·55	6470
Amatol 80/20 ...	1·50	5080

Pressures developed by Ammonium Nitrate, Amatols, and T.N.T.

Ammonium nitrate	Trinitrotoluene	Tons per sq. in. in $0{\cdot}5\times10^{-5}$ sec.
100	0	12·5
99·5	0·5	15·2
99	1	18·3
98	2	20·0
95	5	25·2
90	10	30·5
80	20	38·1
40 (at density 1·55)	60	53·9
0 (at density 1·55)	100	55·0

It will be seen that the addition of 40 per cent. of ammonium nitrate to T.N.T. does not markedly reduce its heat value, rate of detonation, or pressure developed, and that amatol 80/20 has a high content of heat energy, but a rate of detonation and pressure lower than T.N.T. itself. It is, however, still sufficiently violent to fragment shell satisfactorily, and the somewhat slower development of the pressure, together with the high calorific value of the explosive, may be of advantage in enabling the fragments to acquire a

higher velocity. It will also be observed that ammonium nitrate itself under a powerful initial impulse gives rise to a notable pressure, so that that ingredient is not to be looked on as a diluent of the T.N.T., but as an explosive substance, as well as a purveyor of the oxygen in which T.N.T. is deficient.

Smoke.—For the purpose of correct ranging and locating the position of burst, an explosive developing smoke is desirable. Amatol 80/20, when used alone, had the disadvantage that it gave no smoke, as the products of the detonation are colourless gases, thus:—

$$2C_7H_3N_3O_6 + 21NH_4NO_3 = 24N_2 + 47H_2O + 14CO_2\,;$$

whereas, when picric acid or trinitrotoluene detonates, a large quantity of unconsumed carbon is set free, affording a black cloud useful for the purpose of observation.

Mixtures capable of producing a white smoke, useful for aerial observation, were then added, and as a result of investigations as to the best method of securing its dissociation, ammonium chloride in conjunction with the ingredients of amatol was localised at the base of the filling.

Needless to say, there were many other developments in explosives practice during the war, but the example of the train of detonation leading up to the complete detonation of a high explosive shell was chosen to exemplify the subject of this discourse, since it included many features and new problems which had an intimate connection with the technical development of the subject.

To secure the high percentage of detonations that our artillerists obtained with the freedom from prematures which they always demanded, it was necessary to have each part of the somewhat complicated train as nearly perfect as possible not only in design, in order to withstand the effects of rough usage and of set-back in the gun, but also in workmanship, both mechanical and chemical as to purity of materials. This was achieved by the co-ordination of a large number of industries organised on a scientific basis, and these were becoming every day more and more efficient. War is now so highly organised that for its successful prosecution all the technical industry of the country is brought under requisition, and to succeed requires a higher development in research, applied methods, and industrial progress than belongs to the enemy.

The effort made by this country in the time of stress to overcome deficiencies in these respects was successful as a great technical achievement, and should be an encouragement to us to look forward to an equal development of our scientific industries under the stress of a competitive peace.

Stellar Parallax.[1]

By SIR FRANK DYSON, F.R.S.

IN the past ten years a number of the large telescopes of the world have been applied to the determination of stellar parallax. The principle of the method is well known and is extremely simple, merely consisting in the detection of the small annual movement of a near star with reference to more distant stars caused by the different position occupied by the observer in consequence of the earth's annual revolution round the sun. The whole difficulty consists in the extreme minuteness of the angle to be measured. If two railway lines, starting at King's Cross, instead of remaining parallel, met at Newcastle the angle between them would be of the order of the angle to be measured in finding the distances of the nearest stars. To form an idea of what is now being done by large telescopes using photographic methods, imagine two plumb-lines 5 ft. apart. They are sensibly parallel, but actually meet at the centre of the earth, and the angle between them is $0{\cdot}05''$. An angle of this size is measured with an accuracy of $\pm 0{\cdot}01''$. Results of this high value were first obtained by Prof. Schlesinger at the Yerkes Observatory. At the present time the observatories of Allegheny, Greenwich, McCormick, Mount Wilson, Yerkes, and a number of others are engaged on a comprehensive programme. At Greenwich we determine the parallaxes of fifty stars a year; at some of the American observatories many more.

Necessarily, a good deal of care is required both in taking the photographs and in measuring them. The image of a star may have a diameter of $2''$ or $3''$, and the position of its centre should be measurable to between 1/50th and 1/100th of this amount. The methods of measurement present some points of interest which need not be described now, but a word or two about the precautions to be observed in taking the photographs may be of interest. The images must be as circular and uniform as possible. (1) The guiding of the telescope must be as perfect as possible. (2) The lenses of large object-glasses must be adjusted with great care so that there may be neither tilt nor eccentricity between them. (3) Photographs should all be taken with the telescope pointing in the same direction. One cannot be taken when the field is east and another when it is west. Atmospheric dispersion and possibly minute flexure of the lenses cause slight deformation of the images which may be scarcely visible to the eye, but appear in measures. (4) The star the parallax of which is being determined and the comparison stars should have approximately

[1] From a discourse delivered at the Royal Institution on Friday, April 29.

equal images on the photograph. This is secured by means of a rotating shutter, a neutral screen, or the use of a grating in front of the objective.

The purpose of (3) and (4) is to make any residual errors the same for the parallax star and the comparison stars, and so far as possible the same on all photographs.

The knowledge of the distance of a star gives us immediately its luminosity or the amount of light it emits as compared with the sun. There is a very great range in luminosity even for stars of the same spectral type. Now the stars have been arranged in an order according to the spectra, which agrees fairly well with their order in colour from blue to red, and is essentially an arrangement according to temperature. This may be regarded as an extremely good first approximation to a classification of stellar spectra. But it does not detect any differences attributable to absolute luminosity, though presumably density and gravity at the surface layer of the star from which the lines in the spectrum have their origin must be widely different.

A few years ago a very fruitful investigation was commenced at Mount Wilson by Adams and Kohlschuter. By a close comparison of the spectra of stars of the same spectral class, but differing greatly in absolute luminosity, they detected lines the intensities of which differ. Adams and his coadjutors at Mount Wilson have pursued this research with very great success. They have found in stellar spectra a number of pairs of neighbouring lines, one line of each pair being independent of the absolute luminosity, while the other changes in intensity with the luminosity of the star. They have measured the relative intensities of these pairs of lines, and compared their measures with the luminosities of 650 stars already known through the trigonometrical determinations of parallax made at Allegheny, McCormick, Mount Wilson, and Yerkes. Thus they have found the luminosities of stars corresponding to different intensities of the lines. They have recently published a catalogue (*Astrophysical Journal*, March, 1921) giving the luminosities and parallaxes of 1680 stars.

The advantage of this method is that it extends the range of parallax determinations beyond the limit (say) 0·02″ of the trigonometrical method, the limit of the spectroscopic method being determined only by the capacity of large telescopes to give measurable spectra. In the table a comparison is given with unpublished results at Greenwich obtained by the trigonometrical method:—

No.	App. mag. m.	Mag. at 10 parsecs m.	Parallax Mount Wilson ″	Parallax Greenwich ″
B 1673	5·6	4·2	0·052	0·034
B 2897	6·1	4·3	0·044	0·040
B 2971	7·8	7·2	0·076	0·088
C 1604	8·2	4·9	0·022	0·015
B 3983	6·9	5·7	0·058	0·052
B 4181	5·0	1·7	0·022	0·041
B 4234	6·4	2·4	0·016	0·013
C 2242	7·6	5·4	0·036	0·046
B 4322	4·8	3·6	0·058	0·031
B 5009	4·8	3·8	0·158	0·171
B 6129	6·6	6·7	0·105	0·076

Comparison of these results, obtained by entirely different methods, shows the accuracy of 20 per cent. claimed for Mount Wilson, and $\pm 0·010''$ for Greenwich is reached.

A third method is being employed extensively for determining stellar distances depending on the fact that the masses of stars lie within very restricted limits. It is applicable only to double stars, and depends on Kepler's third law, $M+m=a^3/P^2$, where M, m are the masses, a is the mean distance between the components, and P the period of a double star. When P is known and $M+m$ assumed, a is found, and, further, as the cube root of $M+m$ is involved, an error in the assumed mass produces a much smaller error in the mean distance. Now the *angular* mean distance is determined by direct observation for all double stars the orbits of which can be calculated. At the present time this amounts to more than 150. But it has been shown by Hertzsprung and Russell that for double stars which have completed too small a portion of their orbits for their periods to be known it is still possible to obtain their "hypothetical" parallax with considerable probability. The method has been recently applied at Greenwich to obtain the parallaxes of a large number of stars, and the accordance with the results found by the trigonometrical and spectroscopic methods is very satisfactory (see a paper in Monthly Notices R.A.S., November, 1920, by Messrs. Jackson and Farmer).

I believe there is in preparation by American astronomers a catalogue giving the parallaxes of 3000 stars, about half of which have been determined by two at least of these three methods. We may expect that in the course of a very few years the distances of all stars visible to the naked eye in the northern hemisphere will have been determined, as well as those of many fainter stars. This great accession of knowledge of stellar distances carries with it a corresponding increase with reference to the luminosities, sizes, masses, densities, and velocities of stars of different spectral classes.

Obituary.

WILLIAM WARDE FOWLER. 1847–1921.

WARDE FOWLER, like Arthur Sidgwick, was one of the men we can least spare—a classical scholar of distinction and a writer of great charm who sympathised warmly with the aims and methods of science, and strove to give them a larger place in the life of his University. It would scarcely be possible to gain a clearer insight into the strength and weakness of an Oxford education as it was nearly twenty years

ago than by reading his "Oxford Correspondence of 1903" (Blackwell, Oxford; Simpkin, Marshall and Co., London) between a college tutor and one of his pupils whose eyes are opened to the meaning of research by meeting a Zürich Professor in the Long Vacation. Warde Fowler's opinions and the long experience on which they were based appear in the charming letters of the tutor. We owe it to him and many others like him in this respect that the years since 1903 have brought a steady growth in the amount of original work and in the significance attached to it by the University.

In the brief space available I do not propose to say more of Warde Fowler's writings, excellently described in the *Times* of June 16, than just this—that he brought to his classical work the spirit of the naturalist, always seeing through the beautiful veil of literature to the everyday human lives and interests that lay behind, and as he delighted in them himself, so he made them a delight to others.

He was a most interesting and arresting lecturer, and had the supreme gift of selecting and describing an observation so that it both illuminated and fixed in the mind some far-reaching conclusion. No one could forget that the lines of bird-migration are determined, and may be varied, by sight and memory, after hearing him tell of the misty autumn day when he stood on the chalk cliff near Swanage and watched the little bands of swallows arriving from the west and flying round the English coast to the north of the Isle of Wight, on their eastward journey, to cross near Dover; and lo! as he stood watching, there suddenly arrived a band which acted very differently, circling up into the air and darting directly eastward across the sea; and then, following their flight, he saw for the first time what they had seen, that the mist had lifted and the Needles were in sight. Then, and then only, had they taken the direct and shortest eastward route along the chalk midrib of the Isle of Wight.

Or he would tell of the thrush that, in the middle of its song, saw one of its young carried off by a cat, and expressed its emotions by singing more loudly and passionately.

Or it was the want of attention in observation that was illustrated by the fishermen, he being one of them, who, after their day's sport was over, began discussing the position of the fins of the trout, and, unable for the life of them to remember the arrangement, paid a visit to the larder to find out!

It is interesting to compare with this experience the unconscious yet keen attention and the sure memory which come into play when man observes his fellow man. And this is to be expected. There have been long periods when the recognition of a man by his shoulder or head seen from behind, or by his gait, has meant the difference between life and death.

The memories I have recalled belong to the early days of the Ashmolean Natural History Society of Oxfordshire, and probably all are more than thirty years old. The charm and arresting personality of the speaker have left them clear and bright.

E. B. P.

R. E. DENNETT.

MR. R. E. DENNETT, who died in London on May 28 at the age of sixty-four, was a student of the religions, languages, and customs of the indigenous races of West Africa, and his work was marked by great ability and originality. Son of an Anglican clergyman of unusual individuality—a Devonshire man—Mr. Dennett was born at Valparaiso, and had his early education at Marlborough School. He went out to West Africa in his early twenties, and he spent more than forty years in Nigeria and in what are now the French and Belgian Congo territories. Comparatively early in his career he was brought into association with that remarkable woman, Mary Kingsley, and his mind, already sympathetically disposed towards the native races, received an additional powerful impetus in the same beneficent direction. Thereafter he bent a great part of an intellect naturally strong to the attempt to interpret the character and institutions of the Africans to the reading public in Great Britain.

Mr. Dennett had special opportunities for observation, for in turn he was trader, explorer, and official, a combination not often found in one person. It was (indeed, still is) work highly necessary, for it is probably safe to say that the main impression left upon the minds of most people in Britain as the result of reading the accounts of the Stanley expeditions was that all Africans are absolutely primitive and all at the same stage of development. Nothing could be more grotesquely inaccurate, and Mr. Dennett's careful, patient, above all sincere and sympathetic, researches did much to make clear the truth, which is, of course, that the greater facts of man's life are represented among Africans by institutions and observances much the same in root significance as those of Europeans, but in some respects less highly developed. He believed firmly that the most hopeful course in British West Africa was, while suppressing accompaniments of native rule which are inconsistent with individual rights, carefully to preserve and support the main body of African custom, which he held to be essentially just and based upon the life and needs of the people. That is to say, he wished the African to be governed by his own people in his own way, the European Powers keeping the peace while the native races gradually advanced along their own lines.

Of several noteworthy books that by which Mr. Dennett will best be remembered is probably "At the Back of the Black Man's Mind," a close and penetrating study of the great subject indicated by the title. Others are: "Seven Years among the Fjort," "Nigerian Studies," "My Yoruba Alphabet," "Universal Order," and "Periodic Law." One of the most painstaking of inquirers,

Mr. Dennett was also one of the most genial and simple-natured of men, and his death will be most deeply regretted by a wide circle here and in Africa.

C.

SIR THOMAS WRIGHTSON, BART., M.INST.C.E.

SIR THOMAS WRIGHTSON, BART., a master of industry in the North of England, died at Neasham Hall, his seat on the banks of the Tees, on June 18, in the eighty-second year of his age. Like his cousin, the late Lord Armstrong, in whose Elswick works he served his apprenticeship, Sir Thomas combined a business aptitude with the qualities which go to make a research worker and inventor. He contributed numerous papers on professional and technical subjects to the Proceedings of engineering and metallurgical institutes and societies with which he was associated, but of his contributions to knowledge the one which is most likely to be remembered is connected with a pastime rather than with his profession. He was an ardent musician in his earlier years, and became interested in the power possessed by the human brain of resolving compound sound-waves into their component notes. He was not satisfied with the theory put forward by von Helmholtz in 1863, and in 1876, when giving a presidential address to the Cleveland Institution of Engineers, he put forward an observation which he afterwards made the basis of a new theory of the mechanism of hearing. This observation was that if the sine curves representing a compound sound-wave are plotted out on a zero line, and if it is supposed that each crest, trough, and "crossing point" on such a tracing could give rise to a stimulus on entering the ear, the time intervals of all the primary component notes could still be recognised. The cochlea, he supposed, must be able to detect these as pressure pulses, and acted not as a resonator but as an hydraulic apparatus. A little later he became involved in public life and in politics, and sat first for Stockton and afterwards for St. Pancras East in the Conservative interest. In 1906 he abandoned politics to devote himself anew to working out the idea he had first put forward in 1876. In 1907 he published a monograph under the title, "On the Impulses of Compound Sound Waves and Mechanical Transmission through the Ear." In this publication he describes and figures a machine of his own invention—an ohmograph he named it—by which he could combine the tracings of two, three or four simple notes into their combined form. Associating himself with Prof. (now Sir) Arthur Keith, a reinvestigation of the finer anatomy of the cochlea was undertaken, with the result that many facts came to light which were favourable to his interpretation of the mechanism of the internal ear, but could not be explained on the supposition that the cochlea serves as a resonator. In 1918 Sir Thomas brought his evidence together in the form of a book which was published by Messrs. Macmillan under the title, "An Enquiry into the Analytical Mechanism of the Internal Ear." The theory thus put forward is at present being subjected to a searching criticism, and if it be too much to claim that anything like finality has been reached, it may be safely stated that the author has made a contribution which has a permanent value for students of auditory mechanism.

Notes.

THE formal opening of the new Intermediate Scale Chemistry Laboratory of the Imperial College of Science and Technology by Mr. A. J. Balfour (the Marquess of Crewe presiding) will take place tomorrow (Friday) at 4 o'clock.

THE annual general meeting of the Research Defence Society will be held at 11 Chandos Street, W.1, on Wednesday, June 29, at 3.30, under the chairmanship of Lord Lamington. Dr. H. H. Dale will give an address on "The Work of the National Institute for Medical Research."

THE Semon lecture for 1920–21 in connection with the University of London will be given at 5 o'clock on Tuesday, July 5, at the Royal Society of Medicine, 1 Wimpole Street, W.1, by Dr. J. Horne, who will take as his subject "The Relationship of the Larynx to Pulmonary Tuberculosis." Admission will be free, without ticket.

A BILL to provide for the time in the British Isles being in advance of Greenwich mean time during a certain period of the year has been presented to the House of Commons.

THE president and council of the Royal Society have appointed Mr. H. Robinson, of the University of Manchester, to the Moseley studentship for research in molecular physics, the funds for which were bequeathed to the Royal Society by the late Lieut. H. G. J. Moseley.

THE John Fritz gold medal has been awarded by the National Societies of American Engineers to Mr. Schneider, past-president of the Iron and Steel Institute, in recognition of his work in connection with the development of artillery.

BY the will of the late Sir Felix Semon, the laryngological library of this well-known throat specialist is left to the Royal Society of Medicine.

A GOLD loving-cup was presented on Friday last by the members of the Royal Institution to Sir James and Lady Dewar on the occasion of their golden wedding.

IN consequence of the illness of Dr. J. Rennie, it has been found necessary to suspend the arrangements made by the Ministry of Agriculture and Fisheries for the examination of diseased bees. The Ministry will issue a further announcement as soon as other arrangements have been made.

AT the evening meeting of the Royal Geographical Society on Monday last the president stated that the

society had heard with great regret of the death of Dr. Kellas, who had been invited to join the Mount Everest Expedition that he might carry out on Mount Everest the experiments in the employment of oxygen at high altitudes which he had already planned to carry out this summer on Kamet. It is feared that Dr. Kellas's death may have been due to his own untiring energy, for instead of resting after his great climb last summer he had spent nearly all the winter in climbing peaks in Sikkim.

CAPT. ROALD AMUNDSEN has asked the Storting by telegram from Nome, Alaska, for 300,000 kroner (about 12,000*l.*) for the purpose of refitting his vessel, the *Maud*, in order to enable him to continue his expedition in the Arctic regions. The *Maud* lost a propeller off Cape Serge, and is to be towed to Seattle for repairs.

As already announced, the Congress of the Universities of the Empire will be held at Oxford on July 5–8. In the morning of July 5 the following subjects will be discussed: "The Universities and the Balance of Studies." (1) The place of the humanities in the education of men of science and men of affairs. (2) The place of the physical and natural sciences in general education. (3) The question of specialism in university curricula. In the afternoon: "The Universities and the Teaching of Civics, Politics, and Social Economics." "The Universities and Secondary Education." (1) The frontiers of the secondary school and the university. (2) The influence of university entrance requirements upon the curricula of secondary schools. In the morning of July 6: "The Universities and Adult Education." (1) Lectures for the general public within the walls of the university. (2) Extra-mural work. In the afternoon: "The Universities and Technological Education." In the morning of July 7: "The Universities and Training for Commerce, Industry, and Administration." "The Universities and the Training of School Teachers." In the afternoon: "University Finance." In the morning of July 8: "The Universities and Research." In the afternoon: "Interchange of Teachers and Students." (1) The institution of a Sabbatical year for professors. (2) Provision of temporary junior posts for graduates of Colonial and foreign universities. (3) How to raise funds to make a trust for the promotion of the migration of students. (4) Equivalence of entrance examinations. (5) Mutual recognition of study and examinations.

A NATIONAL exhibition of maternity and childhood has been organised in Paris from June 15 to July 25. The exhibition is located in the Jardin Zoologique d'Acclimatation, Bois de Boulogne, and is divided into five sections. The object of the exhibition is to encourage larger families than at present obtain in France, and in the various sub-sections such subjects as the small birth-rate, its causes and prevention, infantile mortality, and the rearing of large families are dealt with. Conferences, *fêtes*, and sports are included in the programme. A large and influential committee has charge of the organisation, which is under the patronage of the President and Ministers of the Republic, the secretary-general being M. Em. Brocherioux.

A PROVISIONAL programme for the Paris Conference of the Museums Association, to be held on July 12–18, has been issued. The headquarters of the association while in Paris will be the Hôtel Moderne, Place de la République, and the meetings will be held at the Musée National D'Histoire Naturelle, Rue Cuvier. Papers on museum administration and numerous tours of French museums have been arranged, and there will be at least one joint meeting with the French Museums Association. Information regarding tickets, passports, and hotel accommodation, both for those attending the meeting and for those contemplating a more extended tour after the conference, can be obtained from Mr. W. J. W. Barrier, 31, Lime Grove, Shepherd's Bush, W.12.

A CONFERENCE of the International Union against Tuberculosis will be held in London, under the auspices of the National Association for the Prevention of Tuberculosis, on July 26–28. The annual conference of the National Association will be merged in the larger gathering. The object of the International Union, which was founded last year, is to promote an effective combination of the nations of the world against tuberculosis, and its first president is M. Léon Bourgeois. For the occasion of the coming meeting, however, Sir Robert Philip will act as president. Official delegates from countries within the League of Nations, from America, and from authorities interested in the subject, are invited to attend. The principal business of the conference will be a discussion, opened by Prof. A. Calmette, on the modes of diffusion of tuberculosis throughout the races of the world. Sir Humphry Rolleston will open another discussion on the *rôle* of the medical profession in the prevention of tuberculosis. There will be an official reception of the Union by the Lord Mayor of London on July 26, and visits to institutions of particular interest are being arranged.

THE executive committee of the council of the American Association for the Advancement of Science held its regular spring meeting at Washington, D.C., on April 24 last. The business transacted at the meeting is reported in *Science* of May 20, and some of the resolutions will be of interest to men of science in Great Britain. The next meeting of the association will be held at Toronto, and it was resolved that a special committee should collaborate with the local committee for the meeting to invite an eminent British man of science to attend to present papers before the section of the association to which his field of work is related and to deliver a general public lecture. The executive committee of the council also resolved that the British Association for the Advancement of Science be invited to send a representative to the Toronto meeting, and Dr. J. McK. Cattell was elected official delegate of the American Association to the forthcoming Edinburgh meeting of the British Association. A further resolution, which is of great interest in view of the letters which have appeared in our columns on the same topic, asks for the restoration of the privilege of duty-free importation of English scientific works by recognised educational institutions and faculties. The committee also directs the attention of Congress to the burden which would be im-

posed on scientific education and research by the proposal to repeal that part of the Tariff Act of 1913 which permits the duty-free importation of scientific materials, and on behalf of its 12,000 members asks for reconsideration of the suggestion.

A FURTHER step in the movement towards the standardisation of automobile, motor-cycle, and cycle parts has been taken by the British Engineering Standards Association in the formation of seven sub-committees the subjects and chairmen of which are as follows:—Nomenclature, Major C. Wheeler; Steels, Mr. A. A. Remington; Small Fittings, Mr. W. D. Williamson; Electrical Fittings, Mr. E. Garton; Shafts and Shaft Details, Mr. L. A. Legros; Wheels, Rims, and Tyres, Lt.-Col. D. J. Smith; and Cast Iron, Dr. L. Aitchison. Before the sub-committees actually embark upon the detailed work the various organisations concerned are being consulted in order to ensure that the proposed *personnel* meets with their approval as adequately representing their respective interests. In the meantime, technical data in regard to the specific subjects to be taken in hand immediately are being collected, and this should greatly facilitate the progress of the work as soon as the membership of the sub-committees is officially approved.

DR. A. C. HADDON selected as the subject of the Huxley memorial lecture, published in the Journal of the Royal Anthropological Institute (vol. l., part ii.), "The Migrations of Cultures in British New Guinea." He remarks that along the coast a traveller notices a series of cultures, some evidently related to one another, while others are as obviously unrelated. The differences indicate that there is no immediate relation between them, though their affinity points to a common origin. The cultural problems of the south-eastern peninsula and the outlying islands are in the main quite distinct from those of the west, and the differences between these two groups indicate clearly that there cannot have been any extensive cultural movements from the Papuo-Melanesian to the western Papuan. We are driven, on general grounds, to the supposition that the cultures of the southern coast of New Guinea came down more or less from the north. The difficulty is that we have as yet no precise knowledge of the inhabitants of the interior of the island, and the socio-religious customs of the natives of many of the coastal areas have yet to be investigated. The lecture, with its appendix of material, is a valuable contribution to our knowledge of the ethnology of New Guinea.

IT is a significant indication of the change of view in relation to anthropometry that in his paper on "Ancient Skulls from Greenland" Mr. W. E. Le Gros Clark (Journal of the Royal Anthropological Institute, vol. l., part ii.) remarks that many attempts have been made to deal with the various races of man as the zoologist deals with the various species of mammals; to find some specific features which may serve to differentiate the skull of one race from the skull of another, in the same way that the concave post-orbital process distinguishes the skull of a fox from that of a dog. "This method was carried to an extreme by Sergi when he subdivided the Mediterranean Race into a number of varieties, each characterised by the shape of the cranium as seen from above. These attempts have all failed, and it must be realised that the variation of individual skulls of modern races is so great that it is often extremely difficult to assign an isolated skull of unknown origin to a definite race with any degree of certainty." Mr. Clark points out that the construction of a type contour obviates these difficulties, and on its use the future of the science of craniology must depend.

ALL lovers of Oxford will welcome the pamphlet issued by the Clarendon Press in which Mr. H. E. Salter, after an exhaustive study of the college records and other literature, discusses "The Historic Names of the Streets and Lanes of Oxford. Intra Muros." It is remarkable that during the last 900 years only two new streets have been constructed—New Road in 1770, and King Edward Street about a hundred years later. The old lane near Christ Church meadow was called Shulinstoke, the pool above the mill where the cucking-stool was used; The Seven Deadly Sins was perhaps the sign of an inn, or a set of seven small cottages; Bocardo Lane was called after the Bocardo or Town Prison; the Turl was the Twirling Gate on the foot-way which led from Ship Street to Broad Street, and is not, like "The Broad," an undergraduates' abbreviation. Broad Street was known as Horsemonger Street in the thirteenth century, and that running from the west end of Broad Street towards the station was Irishman's Street. The author ends by suggesting that Cat Street should be restored for Saint Catherine's Street, Bocardo Lane for St. Michael's Street, and that Alfred Street should be rechristened Vine Hall Lane.

AT the Royal Society conversazione on June 15 an exhibit was given illustrating the life-history of *Chermes Cooleyi*, Gillette. This insect has been recently observed in Britain. It is spreading rapidly throughout the southern counties of England, and occurs in two localities in Scotland. A study of it is being made by Mr. R. N. Chrystal under the direction of the Forestry Commission with the view of working out its biology and determining its relation to Douglas fir and Sitka spruce plantations in this country.

VOL. LVIII. (pp. 483–576, 1920) of the Proceedings of the U.S. National Museum contains a revision of the Nearctic ichneumon-flies of the genus Apantales by Mr. C. F. W. Muesebeck. As natural controlling agents of injurious insects many species of Apantales play important parts. Thus the larvæ of the common cabbage butterfly, those of the gipsy and brown-tail moths, and many cut worms and army worms are heavily parasitised by these insects. There appears to be no authentic record of an Apantales having been bred from any insects outside the Lepidoptera. In this revision 164 species are known to the author, and a list of their hosts is appended wherever known. On pp. 327–62 of the same serial Mr. R. A. Cushman revises the ichneumon-flies belonging to the tribe Ephialtini, the members of which are internal parasites of Lepidopterous pupæ.

WITHIN a year after the armistice some thirty nations and States agreed to two series of international air maps, the general and the local. The Geographical Section of the General Staff has undertaken the work of those sheets which fall within the British Empire. In the *Geographical Journal* for May Lt.-Col. E. F. W. Lees discusses the proposed maps at some length. For the general map it appears that Mercator's projection, despite all its disadvantages, is to be employed, principally because of its use in navigation and the general training of pilots on naval lines. The scale is to be 3 cm. to 1° of longitude at the equator, and the index is to be based on the index of the international million map. An overlap of 1° of latitude and 3° of longitude is to be allowed. As regards colouring and symbols, some departures must necessarily be made from the conventional usages of maps for terrestrial purposes. Experience has shown what features are of value to the airman in locating his position and finding his way. All water is to be blue; aeronautical information, such as positions of aerodromes, seaplane stations, lightships, etc., black; roads, deep yellow or burnt sienna; railways red, because of their conspicuousness to airmen; and woods green. Red is also to be used for buildings. Hill shading for the depiction of relief on the general map was recommended by the International Convention, but the employment of the layer system does not lack advocates. The general ground colour is to be pale green for ground covered with vegetation and pale buff for arid ground. Names apart from those applying to aeronautical information will be sparingly used. The local maps are to be on a scale of 1 : 200,000. For these the International Convention does not suggest the use of Mercator's projection. An innovation that will cause some criticism is the adoption of a new system of coordinate reckoning. Latitudes commence with zero at the South Pole and increase to 180° at the North Pole, and longitudes begin with the present 180° as zero or 360° and run eastward round the sphere. This departure from convention seems to carry no merits beyond the elimination of the letters N. and S. in latitudes and E. and W. in longitudes.

THE Report of the Director, United States Coast and Geodetic Survey, for the year ending June 30, 1920, is of considerable interest on account of the large number of charts it contains, many of which illustrate the extent of hydrographic survey along important steamer tracks on the coasts of America and its possessions. These maps show how much detailed work is required even in much-frequented channels in order to ensure safe navigation. Special emphasis is laid on the need for wire-drag surveys on the rocky coasts of the Pacific States and Alaska. The Director also makes a plea for the survey of Alaska, and shows in several charts and diagrams how little has already been done. Ninety per cent. of the coastal waters are uncharted; where surveys have been made a startling number of dangers to navigation has been discovered. It is essential also that the survey control points in Alaska should be linked up with other surveys of the United States or Canada. Operations have been begun with the co-operation of the Canadian Government for a line of triangulation from Seattle through south-eastern Alaska, the so-called "panhandle," to the Yukon Valley and Bering Strait. The report indicates the progress made in the detailed survey of the Virgin Islands recently acquired from Denmark.

MR. A. W. GILES has studied and mapped the eskers in the vicinity of Rochester, New York, in Proc. Rochester Acad. Sci. (vol. v., pp. 161–240). A very useful bibliography of 126 papers is appended. Mr. J. G. Goodchild's Eden Valley papers (*Geol. Mag.*, 1875, and Quart. Journ. Geol. Soc., vol. xxxi.) might be included, since he was one of the first authors to urge a sub-Glacial origin for gravel ridges. Mr. V. Tanner's detailed description of the Lapland eskers (*Bull. Comm. géol. Finlande*, 1915) might also be added as an elaborate modern study of the deposits of continental ice. Mr. Giles systematically reviews objections to the sub-Glacial theory of eskers, and concludes firmly in its favour. The knolls on esker-crests and the interruptions in chains are accounted for in several reasonable ways, and it is made more than ever apparent that an unnecessary amount of mystery has grown up round the subject since Hummel's explanation was published nearly fifty years ago. Even the nomenclature has become confused, and Mr. Giles's sentence, "The Swedish word 'os,' plural 'osar,' sometimes written 'as (asar),' has priority," contains, unfortunately, two linguistic errors.

THE history of geological research in the United States has been enriched by Mr. G. P. Merrill's "Contributions to a History of American State Geological and Natural History Surveys," a volume of 550 pages, published as Bulletin 109 of the Smithsonian Institution in 1920. Numerous portraits of the pioneers are given, and a great deal of instructive information may be gathered as to the functions of local surveys and their relations to other State Departments. Much of the material was originally collected by the U.S. Geological Survey, which has now permitted publication in this convenient and comprehensive form. The author refers also to Bulletin 565 of that Survey, in which Mr. C. W. Hayes summarised the work of the Surveys of the separate States.

RECENT drainage operations in the Awanui Swamp in North Island, New Zealand, have disclosed the existence of an elaborate drainage system many miles in extent which, there is good reason to think, may antedate both the Maori and their predecessors, the Moriori. The discovery is described by the *Times'* New Zealand correspondent in the issue of June 16. The drains are said to be uniformly about 5 ft. in width and 5 ft. in depth, with regularly sloped sides, the bottom being about $3\frac{1}{2}$ ft. wide. They run for many miles across country in parallel lines perfectly straight, with numerous right-angle cross-drains. An indication of their age is afforded by the fact that in places huge trees of slow growth have grown up in the drains after their formation and decayed. The remains of deeply embedded posts with sharpened ends on a mound in one part of the swamp indicated that

it had been the site of a building. A remarkable piece of carved wood in the shape of a lintel, which was found at a depth of 5 ft., has just been secured for the Auckland Museum. In its centre is represented a human figure "almost gorilla-like in appearance"; it has a broad, wedge-shaped head with projecting ears, small broad nose, and a large oval mouth with small tongue. The body is small, short, and squat. The outstretched hands of the figure rest upon a perforated framework spreading right and left, the ends of which each terminate in a saurian-like head. Water-worn stones of the size of a hen's egg which have human features carved on them have also been found. The antiquity of these remains, as well as their style and technique, would appear to preclude their attribution to either Maori or Moriori.

THE American Association for the Advancement of Science, the National Academy of Sciences, and the National Research Council have appointed small committees which held a joint meeting on April 9 last to consider the problem of the conservation of the natural resources of the United States (*Science* of June 3). A resolution was passed recommending that the committees already in existence should function as a joint committee on national conservation, and at subsequent meetings of the three organisations represented the resolution was confirmed, and funds were provided for defraying the immediate expenses of setting up an executive and secretarial agency for the prosecution of the work. The main objects of the organisation which is to be established are stated under five headings; first, to direct scientific research so that it may bear more directly on the problems of conservation, a consideration which will involve a wide knowledge of the scope of any problem, and its relation to the programmes of research in other fields of work; secondly, the collection of data relating to natural resources, and their interpretation in relation to the economic, industrial, and social welfare of different regions, and of the nation as a whole; thirdly, to introduce the principles of conservation into the curricula of educational institutions; fourthly, to lead a campaign of popular education in the meaning of conservation; and fifthly, to correlate the efforts of existing agencies which are striving for conservation in their own particular fields. We shall await with interest the development of this scheme for economising the natural resources of the United States.

DRY weather has been persistent in England during several months, and now that we are more than half-way through the first month of summer the absence of rain has become serious. The observations at Greenwich, which very fairly represent England, show that the conditions are most exceptional. The Greenwich rainfall was below the normal for each of the eight months from October, 1920, to May, 1921, and compared with the average for 100 years the deficiency of the period is 6·21 in.—approximately equal to the normal rainfall for the four months February to May. There have, however, been only two months, November and February, with the rainfall less than an inch. The total measurement of rain for the eight months is 9·32 in., which is 60 per cent. of the average. An examination of the Greenwich observations for the last 105 years shows only one corresponding period as dry, the rainfall for October, 1879, to May, 1880, amounting to 8·24 in., a deficiency of 7·29 in. October, 1873, to May, 1874, had 9·60 in. of rain, and the next driest was apparently October, 1897, to May, 1898, with 10·50 in. There have been several spring droughts in the last 100 years, and for the four months February to May there have been ten years with the total measurement less than 4 in. This year the measurement for February to May was 3·78 in. The years with the smallest measurements for the corresponding period are 1834 with 2·60 in., 1857 with 2·76 in., 1863 with 2·90 in., and 1874 with 3·16 in. Temperature throughout the past eight months was abnormally high, the mean for each month at Greenwich being above the average and the excess for the whole period 2·3°.

AN interesting paper on the cause of quenching cracks in steel was presented at the May meeting of the Iron and Steel Institute by Messrs. Honda, Matsushita, and Idei. The cause is generally believed to be (1) the non-uniform distribution of temperature in the specimen during quenching and (2) the difference in martensitic expansion of adjacent parts during quenching. A closer examination of the phenomena, however, shows that the true cause is not so evident, for the sound due to cracking is often heard some ten seconds after quenching. In small pieces of steel the periphery is harder than the central portion only in a mild quenching; with a medium quenching the hardness is nearly equal throughout; while with hard quenching the periphery is always softer than the interior. This anomalous phenomenon is explained by the presence of arrested austenite in martensite. The quenching cracks in small pieces of steel occur when the hardness in the central portion is much greater than in the periphery, and they are attributed to the stress caused by the difference in the specific volumes of austenite and martensite. The specific volume of the former is smaller than that of the latter, and hence the central portion exerts a large tangential tension on the periphery. Since the difference in the specific volumes increases as the temperature falls, the cracking usually takes place when the temperature of the quenched specimen approaches that of the room. In a hard quenching the hardness gradually increases with the lapse of time owing to the gradual transformation of the arrested austenite into martensite.

MR. A. S. E. ACKERMANN'S first paper dealing with experiments with clay in its relation to piles was the subject of a note in NATURE for March 27, 1919. In his second paper on the same subject—read before the Society of Engineers in October last—the author takes the opportunity of correcting some errors which appeared in the first paper, and points out that further work has confirmed all the previous conclusions excepting that the effect of temperature on the supporting capacity appears to be limited to stresses below the pressure of fluidity, and that the sides of a hole appear to crush in before the statical

head is equal to the pressure of fluidity. Unquestionably the most interesting of Mr. Ackermann's results is that clay possesses a pressure of fluidity at which the loaded pile sinks through the clay without further increase in the load. This critical pressure depends upon the percentage of water present, being greater with less water. Mr. Ackermann has added to his former work in the direction of experiments designed to separate the work done against frictional resistances from that done in displacing the clay, and finds that the former is by far the larger quantity. A number of experiments have also been made on chalk, and the author finds that wet powdered chalk has a modified pressure of fluidity, and that the water-content affects greatly the properties of chalk. There is a marked difference in the physical properties of powdered chalk as compared with precipitated chalk. The adhesion and cohesion of wet chalk are much less than those of clay; clay is hygroscopic and chalk is not.

THE *Daily Mail* of June 13 published an article by a scientific correspondent under the sub-heading "Can Eyes Radiate Energy?" which gives some account of a new instrument showing that "rays proceed from the eye which are capable of being registered just as wireless messages are detected." Dr. Charles Russ, the inventor of the instrument, writes to us stating that the paragraph constitutes a breach of confidence on the part of someone to whom the instrument was shown. It was intended that the phenomenon should be announced at the Ophthalmological Congress at Oxford on July 7, and some annoyance has been caused to Dr. Russ by this premature disclosure.

MR. A. RISDON PALMER is bringing out through Messrs. George Bell and Sons, Ltd., a series of Handbooks of Commerce and Finance planned to meet the need of a simple and graphic presentation of the fundamental principles of commerce and finance. The first three volumes, dealing respectively with "Transport and the Export Trade," "The Import Trade: Mixing Commodities," and "The Use of Graphs in Commerce and Industry," will be ready shortly.

Our Astronomical Column.

THE METEORIC RADIANTS OF JUNE 25–30.—Mr. Denning writes:—The possible occurrence of an abundant meteor shower from Pons-Winnecke's comet will attract a great number of astronomical observers to watch the heavens. The moon will rise late, and, being at her last quarter, will not offer any serious impediment to observation.

There are a considerable number of radiant points visible at this period of the year, though the usual rate of apparition is not nearly so great as in the two following months of July and August.

The great shower of Perseids probably begins at the end of June, and the radiant is then situated at about $0°+36°$. As it may prove useful for reference, a list of the principal radiant points observed in past years between June 25 and 30 is appended:—

° °	° °	° °	° °
0+36	238+47	282−12	314+61
24+42	245+64	282−24	320+11
30+36	260−24	291+52	320+21
43+37	261−12	291+60	334+57
48+44	261+4	294+40	334+28
161+58	263+63	304+23	342+39
193+57	270+47	305−12	354+39
213+53	270+30	314+47	354+77

REPORT OF THE KODAIKANAL OBSERVATORY FOR 1920.—It has already been mentioned in this column that direct comparisons of the solar lines with those of cyanogen and iron gave results fairly near those predicted by Einstein, but since the shifts were different for different substances, and also not proportional to the wave-length, they could not be wholly due to a gravitational effect. Tests made on the Venus spectrum gave further evidence of the shift being in part an "earth effect." A considerable improvement has been effected in the Venus spectra by using "Barnet Ultra Rapid" plates hypersensitised with ammonia; these enabled a very narrow slit to be used. When the terminator was placed normal to the slit, no evidence was obtained of an inclination of the spectral lines due to rotation of the planet. A recent letter from the director states that further photographs will be taken to test the rotation in sixty-eight hours about a highly inclined axis that was recently provisionally announced by Prof. W. H. Pickering. It was found that change of altitude produced no change in the wave-lengths in the Venus spectra, the range of altitude extending from below 20° to above 40°.

The use of an ultra-violet spectrograph with a quartz collimating lens demonstrated the solar origin of the ammonia band in the solar spectrum at $\lambda 3360$, since the rotation shift between the east and west limbs was shown.

The spot activity, as indicated by the number of groups, diminished 40 per cent. in 1920 as compared with 1919. It is noteworthy that the spot group associated with the great magnetic storm of 1920 March 22–23 returned five times (1920 January to May), there being a magnetic storm on each occasion.

Unlike the spots, there was an increase in both prominences and hydrogen absorption markings as compared with 1919. A great eruptive prominence seen in 1920 December 31 strongly resembled that seen in the eclipse of 1919 May. A continuous series of spectrograms was secured, which showed the prominence matter ascending rapidly and fading away at a height of 16′ above the limb.

POPULAR ASTRONOMY IN SWEDEN.—We have already directed attention to the *Popular Astronomisk Tidskrift;* Häfte 1 o. 2, 1921, is another number full of interest. We may refer specially to an illustrated article by V. Carlheim-Gyllensköld on Tycho Brahe and his observatory on the island of Hven; many photographs of the present aspect of the latter are given, showing that it is still possible to trace out the outlines of the foundations of all the buildings and instruments. A portrait of Tycho Brahe and a photograph of the house where he was born are also reproduced, together with many relics unearthed from the ruins.

The latitude of Sweden favours observations of auroræ, which are made systematically at several stations. The auroræ of September 28 and October 17, 1920, are described in detail, with diagrams indicating the exact locations of auroral streamers among the stars.

The Second Royal Society Conversazione.

THE second Royal Society conversazione of this year was held at Burlington House on June 15, when Prof. C. Sherrington received the fellows and guests.

Some of the exhibits had been displayed at the first conversazione and were described in NATURE of May 19, p. 377; others were new, and the following brief descriptions have been taken from the descriptive catalogue.

Sir John Dewrance and Prof. E. G. Coker: Apparatus for investigating the action of cutting tools by polarised light. A transparent disc is turned at a slow speed by an electric motor through a worm reduction gear, and the cutting tool of glass or other material is clamped in a slide rest and receives a determinate radial feed from the main drive. The mode of action of various forms of cutting tools is observed in polarised light, and the stress distributions in both work and tool are investigated by this latter means.

Mr. R. N. Chrystal (Forestry Commission): An insect enemy of the Douglas fir recently introduced from America, *Chermes Cooleyi,* Gill. This insect may prove a serious enemy of our two most important exotic conifers, the Douglas fir and the Sitka spruce.

Mr. Percy J. Neate: Recording extensometer for textile yarns, etc. The specimen is secured vertically between an upper grip attached to a spring and a slowly descending lower grip. The movement of the lower grip is therefore the sum of the extensions of spring and specimen. This movement is halved and transmitted to a platen travelling downwards at an angle of 60° to the vertical. The spring is designed for a scale of 12 oz. = 3 in. ordinate, but is calibrated to extend $3 \times 2/\sqrt{3}$ in. at that load. The combined effect is to eliminate spring extension from the abscissæ and excess spring extension from the ordinate.

Mr. William Barlow: The methods of chemical graphic formulæ modified so as to interpret crystal structure by means of models. Certain partitionings of space into similar cells embody the conception that stable equilibrium of a crystal indicates the presence of similarly situated centres of repulsion. In the case of the diamond when regular dodecahedral cells are employed and four cells, forming a tetrahedral group, are allotted to each atom, the symmetry traced by the Braggs is presented by the group centres. The case of benzene is found to be met if, while four cells stand for each carbon atom, one is representative of each hydrogen atom. Further investigation has revealed the general principle that the allotment of the cells among the atoms follows the fundamental valencies; thus a monovalent atom requires one cell, a divalent two, a trivalent three, and a carbon atom four. In a large number of cases an appropriate partitioning into similar unit-cells when fully allotted on the principle just stated yields assemblages of cells almost identical in symmetry and relative dimensions with the corresponding crystals.

Sir Henry Howorth: A Dutch house interior. A *tour de force* in perspective, painted by De Hooge or his pupil Hoogestratten, whose name occurs on a representation of a letter on the table, probably for exhibition at a Kermeez or Dutch fair. The late Lord Kelvin and others were puzzled to know how it was executed, since the picture is painted on three planes; since a different view is seen when looked at from the holes at either end and there are no lenses in the holes, it would be interesting to know how the artist accommodated his drawing.

Prof. R. C. Punnett: Hen-feathered cocks. In some breeds of poultry the cocks are feathered like the hen, lacking the characteristic hackles and sickles of normal cocks. Experiments have shown that the assumption of henny feathering by the cock is due to a factor which behaves as a Mendelian dominant. Castration of such birds leads to the assumption of normal male plumage. Experiments by Goodale in America and Pézard in France have shown that the castrated hen also develops cock feathering. It seems probable that hens and henny cocks alike contain a factor which inhibits the development of the normal cock plumage.

Royal Observatory, Greenwich: Astronomical photographs. (1) Four Franklin Adams chart plates in frame. (2) Solar eclipse, 1919, May 29, showing prominence and corona. (3) Solar eclipse, 1919, May 29, showing surrounding stars. (4) Solar eclipse, 1921, April 8. (5) Sun-spots, 1921, May 13.

The Rev. A. L. Cortie: Astronomical photographs and drawings from Stonyhurst College Observatory. (1) Bright-line spectra of Nova Cygni III., 1920. August 29 and 30 and September 6. The great intensity of Hα is shown on the plate of August 30. (2) The genesis of the great sun-spot group of 1920, March 22–27. The drawings were the last made by the late Br. Wm. McKeon, S.J. They were reproduced by him from drawings made at the telescope, and show the development of the disturbance from 1919, December 27.

Dr. William Wilson: A new form of astronomical model designed for educational purposes. The model, while demonstrating the more familiar motions of the sun, earth, and moon and the various phenomena resulting therefrom, reproduces, in addition, the retrograde motion of the moon's orbital nodes (with its synodic revolution of 346 days) and the forward motion of the moon's apsides (with its synodic revolution of 412 days), and is thus capable of affording a demonstration of the Chaldean "Saros" or eclipse cycle of 18 years and 11 days, with its 41 solar and 29 lunar eclipses, the dates on which these eclipses will occur, and the further differentiation of them into total and partial in the case of the moon, and total, partial, and annular in the case of the sun.

The Meteorological Office: Apparatus for recording atmospheric pollution. Dr. Owens's automatic air filter is an instrument which at the end of every fifteen minutes automatically draws two litres of air through a piece of fine blotting-paper. The darkness of the circle of deposit left on the paper gives an estimate of the amount of suspended matter in the air. Records are shown illustrating the reduction in the amount during the coal strike and the relative importance of domestic fires and factories. The amount of suspended matter is found to be closely connected with the vertical electric force. The reduction in the latter at the end of a fog is illustrated by a record taken at Kew.

The National Physical Laboratory: (1) Paterson-Walsh electrical height-finder. Designed during the war for measuring the height of enemy aircraft, it depends on the Bennett-Pleydell "roof" principle of height measurement. The action of the electrical height-finder is, by means of a sliding bar situated in each sighting plane and passing over a horizontal uniform resistance, to obtain at each station a potential proportional to the contangent of the angle of elevation at that station. These two potentials, combined in series by cables connecting the two stations, and operating across a resistance proportional to B, give a current inversely proportional to the height, and thus a milliammeter may, by marking it with an inverse height-scale, be made to give a continuous indication of the height of any object on which the two planes are constantly sighted. (2) Photomicro-

graphic transparencies (Metallurgical Department). Photomicrographs, shown as enlarged transparencies, illustrating recent work relating to the constitution of various alloys of aluminium. They show typical structures found in the alloys of aluminium with magnesium, copper, silicon, iron, and zinc when treated in various ways. Some illustrate particularly the method of determining the temperature at which the alloys become completely solid by quenching small specimens from various temperatures. The presence of liquid at the moment of quenching makes itself felt by a characteristic fine micro-structure.

The Cambridge and Paul Instrument Co., Ltd.: Darwin-Hill mirror position-finder. This instrument enables the position of an object moving in the air to be accurately recorded in terms of three rectangular co-ordinates. Two horizontal mirrors ruled in squares are placed one at each end of a common base line, the rulings being parallel and perpendicular to the base line. The object is observed through a fixed, but adjustable, aperture sight, and the position of the image in each mirror is marked on the glass surface either continuously or at simultaneous times controlled by telephone or signal. Each mirror gives two co-ordinates for any position of the image, from which the three co-ordinates of the object can be calculated for successive positions. These instruments have been used for the observation of high-angle gun-fire for the preparation of range tables, for checking anti-aircraft gun-fire, and for recording the flight of experimental aircraft, pilot-balloons, etc.

The Science Museum: Gravity torsion balance. This instrument was designed by Baron R. Eötvös, professor of physics at the University of Budapest, in order to determine the variation of gravity over comparatively short distances, and to make experimental investigations on the form of the earth. The instrument has also been used in Hungary for the location of mineral deposits when the density of the mineral differed considerably from that of the surrounding strata.

Radiological Branch, Research Department, Royal Arsenal, Woolwich: Pinhole photographs of the Coolidge radiator tube and photographs illustrating protection in the X-ray examination of materials. (1) Pinhole photographs illustrating the change in shape of the focal spot with current change. (2) Photographs illustrating the various parts of the target of the above tube which emit X-rays under varying conditions. (3) Photographs illustrating X-ray protection when radiographing large metal objects. (4) Photographs illustrating portable set designed and made in the Research Department, Woolwich, with complete protection, for visual examination of materials.

Instrument Department, Air Ministry: (1) Mercury barometer for use on airships. (2) Differential thermometer for airships. (3) Twin-pointer revolution indicator. (4) Gyroscopic turning indicator. (5) Aneroid altimeter with computer dial. (6) Permeameter. (7) Liquid oxygen vaporiser

Mr. A. Leslie Armstrong: Engravings upon flint-crust discovered at Grimes Graves, Norfolk, together with flint implements, upon an ancient living level 3 ft. beneath the present surface. The most important engraving is a wonderfully likelife drawing of a stag, or perhaps an elk, evidently disturbed whilst browsing. One foreleg is raised, the others are buried in herbage. The head is held erect and stalks of grass are shown hanging from its mouth. A second engraved piece has a well-drawn animal's head upon it, apparently that of a hind. Others bear lines and irregular forms on them. All were discovered in September last by the exhibitor upon an ancient living level upon glacial sand 3 ft. beneath the present surface, associated with flint implements of Mousterian type, bone tools, and pottery.

British Museum (Natural History): Fading of museum specimens exposed to light (Sir Sidney Harmer). The object of the experiments was to test the efficacy of "antifade" glasses in protecting specimens from fading. The conclusions reached are (1) that specimens kept in the dark do not fade when subjected to a considerable rise of temperature; (2) that objects exposed to direct sunlight are bleached even if protected by "antifade" glass; (3) that the injurious action of either diffused daylight or strong electric light is far less than that of direct sunlight; and (4) that "antifade" glasses may have some slight advantage in protecting specimens from the bleaching effect of diffused daylight or of electric light.

Department of Geology, British Museum (Natural History): An ancient human skull from the Transvaal (Mr. W. P. Pycraft). Towards the end of 1913 a human skull-cap and temporal bone, and a few other skeleton fragments, apparently of considerable antiquity, were found at Boskop, in the Potchefstroom district of the Transvaal. The skull-cap is remarkable for its great length and parietal width—length 205 mm., breadth 150 mm.—while the forehead is narrow. The skull is dolichocephalic and tapeinocephalic. The auricular height could scarcely have exceeded 125 mm., and from this it may be assumed that the cranial capacity did not exceed 1700 c.c. The precise affinities and geological age of this skull are matters now under investigation.

Department of Zoology and Comparative Anatomy, University College: Cytological preparations.—(*a*) Golgi apparatus; (*b*) polar body, Ornithorhynchus egg; and (*c*) *Anello cromatico*, Dytiscus (Dr. Gatenby).

Dr. C. T. Trechmann: Shell of the recent Pleurotomaria (*P. Adansoniana*) dredged off Barbados, West Indies, in 60 fathoms of water Pleurotomaria is a "living fossil"; possibly only about five specimens of this species are known. Other species occur off Japan.

Zoological Laboratory, Imperial College of Science, South Kensington, S.W.: Effect of pineal gland administration on amphibian melanophores (Dr. L. T. Hogben). Administration of fresh gland or pineal extract causes contraction of the melanophores. This effect first appears after a previous treatment of ten days with tri-weekly administration, and follows each subsequent treatment lasting for six hours and attaining maximum contraction in half an hour. Tadpoles become exceedingly pale and quite transparent in the head region when under treatment while the effect lasts.

The South-Eastern Union of Scientific Societies.

THE twenty-sixth annual congress of the South-Eastern Union of Scientific Societies was held at Reading on June 8–11, under the presidency of Prof. E. B. Poulton, who, in his presidential address on "The Inspiration of the Unknown," showed that entomology was a world in which many workers were still needed, and that great blanks in knowledge still required filling up. Dr. Dukinfield Scott contributed a paper on "The Earliest Land Flora," and brought under notice the work of Kidston and Lang on the Lower Devonian flora, and illustrated by the lantern the structure of Psilophyton, a genus founded by Dawson and only now at last coming to be generally accepted by palæobotanists. Miss G. Lister

read a paper on "Conifers in English Gardens," and illustrated her remarks by a large number of specimens; great interest was shown by the delegates in this popular exposition of native and introduced conifers. A third botanical paper was by Prof. G. S. Boulger on "The Origin of the English Flora."

The Silchester rooms at the Reading Museum were crowded when Mr. Mill Stephenson gave a demonstration on the Silchester discoveries. The thoroughness with which the excavations were carried out revealed a complete picture of Romano-British life, including temple, baths, silver refinery, amphitheatre, hypocaust, dwellings, latrines, and all that went to make up a centre of commercial life of the period. The cemetery remains unexcavated. The city is now again buried, the walls alone showing, whilst outside there still remain the earthworks of an earlier period still, when Neolithic Britons planned a camp of wider dimensions. Roman ornaments in bronze called for special notice, these being beautifully executed. A carpenter's plane was remarkable in that it was of metal, and included screws for adjusting the blade. A visit to Silchester enabled many members to pick up fragments of Roman brick and Gaulish ware. Regret that no portions of the buildings or the foundations had been left uncovered was expressed. It is inconceivable that our British Pompeii was again buried out of sight almost as soon as it was excavated.

A visit to Windsor enabled members to see St. George's Chapel and the King's library and to ascend the Round Tower. Papers were read by the Hon. J. W. Fortescue and Dr. A. V. Baillie. A popular lecture was given by Mr. H. E. Peake on "Racial Types in South-East England," and this gave rise to an animated discussion as to whether all the portions of the Eoanthropus skull had been properly fitted as parts of one and the same skull. It was pointed out that portions of at least three individuals had been found. A paper by Prof. John Percival on "Species and Races of Wheat" was of valuable economic interest. Growing plants of *Aegilops ovata* were exhibited and the part it has taken in the evolution of modern wheat expounded. Specimens of various wheats were shown, including the hard, snow-resisting *Triticum spelta*.

The afternoon excursions included a visit to the relics of Reading Abbey, of which the Chapter House is the most important and extensive. The hall measured 79 ft. by 42 ft. One of the tablets on the wall commemorates that ancient musical composition, "Sumer is icumen in," which is stated to have been written down at the abbey about A.D. 1240. A visit to the economic garden of Dr. J. B. Hurry showed the great care here exercised to make the garden of an educational nature. The medicinal plants growing numbered twenty-five, food plants twenty, fabric plants eleven, and dye plants twenty; whilst the herbal garden contained a very large number of useful plants which were grown extensively in the Middle Ages, and alluded to by Chaucer, Spenser, Shakespeare, and others. In the museum attached were many commercial derivatives from the plants. A fine fabric made from the common nettle was noticeable. Archæologists paid an afternoon visit to the quaint Upton Court, with its many-gabled roofs and its hidden priest-holes, and to Padworth and Aldermaston churches, when Mr. C. E. Keyser acted as guide. The University College was also visited, after which the party proceeded to the Experimental Gardens at Shinfield.

It is worthy of note that Reading Museum possesses a copy in needlework of the famous Bayeux tapestry, executed by the Leek Needlework Society. We remember that when we last saw the original at Bayeux it had suffered mutilation by a relic-hunter, and the three-cornered piece which had been snipped out, having come into possession of the South Kensington Museum, had been returned to Bayeux, but instead of being replaced in position it was mounted separately on a block. Perhaps it has since taken its proper place in the tapestry and the modern piece which had been worked in been removed.

An important portion of the business of the congress was the complete revision of the rules, which after discussion were passed as presented by the council.

The Orientation of the Dead.

At a meeting of the Royal Anthropological Institute, held on May 31, Prof. H. J. Rose read a paper on "Celestial and Terrestrial Orientation of the Dead." Two forms of orientation were distinguished and illustrated by examples; namely, graves orientated (*a*) on a point in the heavens, as the east; (*b*) on a point on the surface of the earth, *e.g.*, Mecca. The former Prof. Rose called celestial, the latter terrestrial, orientation. The deciding factor was normally the point towards which the face of the buried corpse turned. This point was often the former habitat, whether real or supposed, of the dead man's people.

The author compared the custom, common among many peoples, of burying in or near the hut, or facing towards the supposed home of the man's spirit at or before birth. This was combined with a belief in reincarnation: the ghost, feared and avoided as such, was welcomed when it became a baby, born of a woman of its own clan or tribe; but as the rebirth of some persons, *e.g.* notorious criminals, was not desired, means were taken to place their bodies in such a position that the ghost would get lost. Thus only the desirable people were buried in the normal place or with the normal orientation towards the dwelling-place of their potential mothers or towards Hades, whence in many cases the souls of the new-born come.

Belief in reincarnation, however, need not of necessity lead to the practice of orientation. Celestial orientation was not always possible in low grades of culture which might have no knowledge of any such thing as cardinal points. Where celestial orientation existed such knowledge could not be assumed without further evidence. It might indicate (*a*) the departure of the dead to a land of darkness, marked by the position of the setting sun; (*b*) the departure to a land of light, marked by sunrise. Moreover, as some were too bad to be wanted back on earth, some also (*e.g.*, important chiefs) were too exalted ever to become babies again. Hence to find a cemetery containing a number of bodies most of which face to one quarter while a considerable number face to another rather proved than disproved deliberate orientation. This applies, for example, to the burial-ground of Megara Hyblæa.

Orientation E.–W. was frequently accompanied by orientation N.–S. Houses were frequently constructed so as to facilitate observation of the position of the sun. If this was done, it was a matter of indifference whether the house ran N.–S. or E.–W. The grave was regarded as the house of the dead.

Another possibility was that the grave, as a sleeping place, was so arranged that the rising sun would warm and vivify the sleeper. This applies only to the E.–W. position.

The idea of the journey of souls to a place on earth, but far distant, may often be distinguished from

celestial orientations (a) by the fact that they tend to converge, not to diverge, in direction; (b) by the absence of graves at right angles to the prevailing direction.

They may also be orientated by being placed along a road of spirits. There were three main classes of non-orientated burials, those with (a) an absence of any intelligible arrangement whatsoever, as in the British round barrows, (b) a funeral feast arrangement, as among the Siculi and some Amerindians, (c) a "Sociocentric" arrangement, as among the Wotjobaluk, Omaha, Ponka, etc.

In conclusion, Prof. Rose suggested that if his deductions were sound, they afforded, *inter alia*, a new test of race.

In the discussion which followed the reading of the paper Dr. Rivers, the president, pointed out that Prof. Rose, in coupling reincarnation and terrestrial orientation, had suggested an entirely new connection. In Melanesia orientation was usually terrestrial. There was, however, a form of orientation which, while being celestial, had no connection with the cardinal points. It was in the direction of a home of the dead in the sky, which he connected with the Melanesian variant of upright burial and the custom of burying the dead in the sea with weights attached to their legs. Dr. Rivers suggested, further, that our own practice of laying the corpse on its back may be connected with the home of the dead in the sky. Prof. Elliot Smith referred to the custom of the proto-dynastic Egyptians who buried their dead with the head to the south, while in the second and third dynasties they were buried with the head to the north, in each case towards the country of origin. Mr. H. Peake pointed out that the terrestrial orientation would tend to become celestial as a people in the course of its wanderings lost the memory of the direction of its original point of departure.

The National Academy of Sciences, U.S.A.

THE annual meeting of the National Academy of Sciences was held at the Smithsonian Institution on April 25–27. Unusual interest was taken in the meetings owing to the presence of his Serene Highness Albert I., Prince of Monaco, Prof. and Mrs. Albert Einstein, and Dr. Frank Adams, of Montreal, a foreign associate. In accordance with a precedent of long standing, President Harding received the academy.

On Monday evening, April 25, the Prince of Monaco gave an address, illustrated by moving pictures, on his researches in oceanography, for which the Agassiz medal, founded by the late Sir John Murray, was awarded to him by the academy in 1918. After the address the Prince graciously received the members of the audience at a reception held in the National Gallery of Art.

On Tuesday the president, Dr. C. D. Walcott, extended a welcome to Prof. Albert Einstein on behalf of the academy, to which Prof. Einstein briefly responded, expressing his sense of pleasure at being present at the meeting of the academy and receiving its welcome.

On Tuesday evening, at the annual banquet, the presentation of the academy's medals was made. The Mary Clark Thompson medal, for eminence in researches in palæontology and geology, was awarded for the first time to Dr. Walcott for his classic studies in Cambrian palæontology. The Agassiz medal for 1918 was presented to the Prince of Monaco. The Agassiz medal for 1921 was presented to Admiral Sigsbee for his investigations, including deep-sea soundings and other oceanographic work, mainly in the Gulf of Mexico. The Henry Draper gold medal, for eminence in astronomical physics, was awarded to Prof. P. Zeeman, of Amsterdam, for his discovery of the so-called "Zeeman effect" and for the study of the influence of magnetism upon light. In Prof. Zeeman's absence the medal was communicated through Dr. Hubrecht, secretary of the Netherlands Legation.. The Daniel Giraud Elliot medal was awarded to Dr. Robert Ridgway for his studies of the birds of North America, especially part viii. of his "Birds of North and Middle America," which has recently appeared. The Hartley gold medal for eminence in the application of science to the public welfare was awarded to Dr. C. W. Stiles for his work in the investigation and eradication of the hookworm disease in the United States.

At the business meeting on Wednesday, April 27, Dr. Walcott tendered his resignation as president of the academy on account of his desire to lay down something of the burden of administrative work which he has long carried, and in order to be able to devote himself more completely to his studies of palæontology, but at the unanimous desire of the academy he consented to withdraw his resignation for the remaining two years of his term. Dr. George E. Hale resigned the office of foreign secretary on account of ill-health, and Dr. R. A. Millikan was elected to succeed him. Messrs. Hale and Pearl were elected to the council, and the following new members were elected to the academy: Messrs. Frank Michler Chapman, William Leroy Emmet, William Draper Harkins, Ales Hrdlicka, Arthur Edwin Kennelly, William George MacCallum, Dayton Clarence Miller, George Abram Miller, Benjamin Lincoln Robinson, Vesto Melvin Slipher, Lewis Buckley Stillwell, Donald Dexter Van Slyke, Thomas Wayland Vaughan, Henry Stephens Washington, and Robert Sessions Woodworth.

Numerous papers were presented at the scientific sessions. The principal feature was the address of Dr. W. S. Adams, of Mount Wilson Solar Observatory, on his spectrum researches on the motions in the line of sight and the absolute magnitudes of nearly 2000 stars. Dr. Adams pointed out the excellent confirmation of Russell's theory of giant and dwarf stars, and discussed the bearing of the observations on the dependence of stellar velocities upon spectral type and absolute magnitude. He also treated several other questions which are no longer insoluble now that, for the first time, the positions, directions, and velocities in space of such a large and homogeneous mass of stars have become known.

Dr. C. D. Walcott gave a profusely illustrated paper in which he directed attention to the great detail in the structure of the trilobite which he has found by the application of a new photographic process.

Dr. H. F. Osborn, of the American Museum of Natural History, New York, traced the evolution and geographical distribution of the Proboscidea. The two main groups of the mastodons and true elephants were followed, by the aid of skeletal photographs, restorations, and maps, from their original homes in northern Africa and Central Asia in the Eocene through their migrations over Europe and Asia to North and South America by way of Bering Strait.

Another paper of the same general character was given by Dr. J. C. Merriam, president of the Carnegie Institution, on his twenty years of study of the evolution and geographical distribution of the bear family.

Dr. L. R. Jones, of the University of Wisconsin, showed the pathological influence of temperature, and

the relation of it to the adaptability of certain soils and climates to the growth of the principal food crops.

Dr. Simon Flexner communicated the results of experimental epidemics produced in colonies of mice, in which it was shown that the mortality is enhanced by the introduction of fresh subjects after the epidemic has nearly run its course, the recurrence among the original colony seeming to be promoted by the disease of the new individuals.

Novel experiments on the skin temperature of pachyderms, reported by Dr. F. G. Benedict, embraced measurements of the temperatures of the elephant, rhinoceros, and hippopotamus at the New York Zoological Gardens. The difference between the results for these hairless animals and the results for man seem to depend largely on the great thickness of the skin, with accompanying control by outside as contrasted with interior temperature conditions.

A short popular account was given by Dr. C. G. Abbot of his experiments with solar cooking apparatus on Mount Wilson. The application of the solar heat is indirect through an oil circulatory apparatus, including a reservoir in which are inserted the ovens. All kinds of domestic cooking, except frying, and the preserving of fruits and vegetables were carried on. A jar of preserved pears prepared in the solar cooker was exhibited.

In a paper by J. R. Carson and J. J. Gilbert on transmission characteristics of the submarine cable, further employment was made of the extraordinary opportunity enjoyed by physicists during the war owing to the Government control of the Alaskan cable. A valuable paper had been given on the characteristics of this cable by signal corps officers at the academy meeting of 1920. Further applications of the results were now given.

A New Treatment of Sleeping Sickness.

AT a meeting of the Royal Society of Tropical Medicine and Hygiene held on May 20, Dr. Claude H. Marshall, senior medical officer of the Uganda Protectorate, read a paper on a new treatment of trypanosomiasis (sleeping sickness) which had been originated by Dr. S. M. Vassallo, of the Uganda Medical Service, and himself. Remedies injected into the circulation, though they may sterilise the blood, probably do not destroy the parasites in the central nervous system, since the trypanosomes produce thickening and occlusion of the choroid plexus at an early stage of the disease, and thus prevent the passage of drugs from the circulation into the spinal fluid. In 1918, therefore, in a well-marked case of sleeping sickness, an intravenous injection of neokharsivan was made, and three hours afterwards 2 oz. of the patient's blood was withdrawn; 20 minims of the serum was then injected into the spinal canal, and no further treatment was given; twenty-seven months afterwards the patient was quite well, and his blood free from parasites. Of thirty cases similarly treated a large majority were quite well at periods varying from six and a half to twenty-seven months afterwards. The results are supposed to be due only in part to the drug contained in the serum; it is held that an antibody, trypanolysin, is formed in the blood of an infected patient, but that this cannot in ordinary circumstances reach the parasites in the central nervous system. Acting on this view, Dr. Vassallo is now treating cases along similar lines, but without previous intravenous injection of the drug. Later speakers emphasised the value of the work of Dr. Marshall and his colleague; but it was pointed out that it was early as yet to claim that the cases were permanently cured.

University and Educational Intelligence.

CAMBRIDGE.—The Frank Smart prizes for botany and zoology have been awarded to A. J. Smith, Downing College, and G. S. Carter, Gonville and Caius College, respectively.

GLASGOW.—Sir John H. Biles has intimated his intention to retire in September next from the John Elder chair of naval architecture and marine engineering, which he has held since 1891. Prof. Biles has served in many capacities under the Admiralty and the Board of Trade, and is Consulting Naval Architect to the India Office. He received the thanks of the India Council for his services in designing and constructing river craft for the Mesopotamia Expeditionary Force during the war.

The late Mr. William J. Chrystal, chemical manufacturer, of Shawfield Works, Rutherglen, has bequeathed 10,000*l.* to the University, to be applied as the Senate may determine; and also 10,000*l.* to the Royal Technical College, for endowment.

OXFORD.—Dr. E. Mallam, of Magdalen College, has been appointed Litchfield lecturer in medicine for two years as from October 5 next.

Final approval has been given in Convocation to the statute constituting the Delegacy for the Society of Oxford Home Students, and to the decree authorising the loan of 19,000*l.* from the special reserve fund for the completion of the Dyson Perrins Laboratory.

ST. ANDREWS.—Dr. R. Robinson, director of research in the British Dyestuffs Corporation, Huddersfield, has been appointed professor of chemistry and director of the chemical research laboratory in succession to Prof. Irvine, now Principal of the University.

THE award of the William Gibson research scholarship for medical women (the second since its foundation) has been made by the council of the Royal Society of Medicine to Miss Gertrude M. A. Herzfeld, of Edinburgh.

THE *Chemical Age* for June 18 announces that Mr. K. C. Browning, who for many years was Government analyst in Ceylon, has been appointed professor of chemistry and metallurgy at the Artillery College (formerly the Royal Ordnance College), Woolwich.

AT the meeting of Leeds University Court, held on June 15, the sixteenth annual report for the year 1919–20 was adopted. The vice-chancellor, Sir Michael Sadler, addressed the court, and stated that the most urgent question before the university was one of finance. The cost of maintenance was almost double that of 1918, and the balance sheet for the current year would show a deficit of 14,000*l.* The present income was about 140,000*l.*, of which 32·7 per cent. came from Government grants, 16·4 per cent. from local education authorities, 14·8 per cent. from endowments, etc., and 36·1 per cent. from students' fees. At present the average cost per student is 75*l.* per annum, and the average fee paid is 27*l.* It has therefore been decided to adjust the fees to meet the difference between the total cost of the education provided and the funds derived from all other sources. Under present conditions this means an increase of 10*l.* per annum in the tuition fees and a small increase in examination fees. The report contains some account of the work in hand in the various departments, and concludes with a list of donations, etc., from which it appears that during the past year the university has received more than half a million sterling in donations, including eight gifts of 10,000*l.* and over, and one of 77,250*l.*, in addition to their annual subscription of 4000*l.* from the Clothworkers' Company of London.

Calendar of Scientific Pioneers.

June 23, 1881. Matthias Jakob Schleiden died.—At first an advocate at Hamburg, Schleiden afterwards held the chairs of botany at Jena and Dorpat. He did much to establish the cell theory, while among his important writings was his "Principles of Scientific Botany."

June 23, 1891. Wilhelm Eduard Weber died.—Professor of physics in the University of Göttingen, Weber was associated with Gauss in some of his investigations, and did valuable work on the definition and determination of electrical units.

June 23, 1896. Sir Joseph Prestwich died.—While in business as a London wine merchant, Prestwich studied the geology of Hampshire and the London basin, the coal supply of England, and the antiquity of man. At the age of sixty-two he succeeded Phillips as professor of geology at Oxford.

June 25, 1868. Carlo Matteucci died.—The recipient in 1844 of the Copley medal for his electrical researches, Matteucci was professor of physics, first at Bologna, and then at Ravenna and Pisa. For some years he was connected with the Italian telegraphs.

June 26, 1793. Gilbert White died.—Educated at Oxford, and for a time senior proctor, White passed most of his life at Selborne. His well-known "Natural History and Antiquities of Selborne" was published in 1789.

June 26, 1831. Sophie Germain died.—A versatile and learned woman, Sophie Germain was distinguished for her mathematical writings on elastic surfaces.

June 26, 1883. Sir Edward Sabine died.—An officer in the Royal Artillery, Sabine made valuable pendulum and magnetical investigations which gave an impulse to the systematic study of terrestrial magnetism. From 1861 to 1871 he was president of the Royal Society.

June 27, 1829. James Smithson died.—Owing to circumstances of birth, Smithson was educated at Oxford under an assumed name. His knowledge of chemistry and mineralogy led to his being admitted as a fellow of the Royal Society in 1787. Most of his life was spent on the Continent, associating and corresponding with men of science. He died at Genoa, leaving his fortune of more than 100,000*l.* to the United States, the Government of which founded the famous Smithsonian Institution.

June 27, 1876. Christian Gottfried Ehrenberg died.—After travelling through East Russia with Humboldt, Ehrenberg became a professor at Berlin, and in 1842 was made secretary to the Berlin Academy of Sciences. He was the first to show that certain rocks consisted of minute forms of animals or plants. His "Mikrogeologie" was published in 1854.

June 27, 1892. Carl Schorlemmer died.—A student of Bunsen's, Schorlemmer in 1858 came to England as assistant to Roscoe, and in 1874 was appointed professor of organic chemistry at Manchester.

June 28, 1897. Paul Schutzenberger died.—The successor of Balard at the Collège de France, Schutzenberger made important researches on colouring matters, the constitution of alkaloids, and on platinum compounds.

June 29, 1895. Thomas Henry Huxley died.—As a naval surgeon Huxley cruised in H.M.S. *Rattlesnake*, and sent home important papers on the Hydrozoa. From 1854 to 1885 he was professor of natural history at the School of Mines. His scientific work embraced vertebrate and invertebrate morphology, comparative anatomy, histology, and palæontology. His lucid essays and crusade for freedom of thought attracted widespread attention, and as "a man and a citizen" he undertook much public work. E. C. S.

Societies and Academies.

London.

Royal Society, June 16.—Prof. C. S. Sherrington, president, in the chair.—H. B. **Dixon**, Dr. C. **Campbell**, and Dr. A. **Parker**: The velocity of sound in gases at high temperatures, and the ratio of the specific heats.—Prof. J. R. **Partington**: The ratio of the specific heats of air and of carbon dioxide. The ratio of the specific heats, $\gamma = c_{-p}/c_{-v}$, has been determined by the method of adiabatic expansion for the gases air and carbon dioxide. The gas was contained in a 120-litre vessel, and the temperature change immediately after expansion followed by a platinum thermometer, with compensating leads of wire 0·001 mm. diameter, the resistance of which was observed by an Einthoven string galvanometer of 0·01 seconds period. The fundamental temperature measurements were made by a mercury thermometer. The results were calculated by the characteristic equation of D. Berthelot, so that deviations from the ideal gaseous state were allowed for. The final results, accurate to 1 part in 1000, are: γ for air at 17° C. = 1·4034; γ for carbon dioxide at 17° C. = 1·3022, whence c_{-p} for air at 17° C. = 0·2387 cal. and c_{-p} for carbon dioxide at 17° C. = 0·1996 cal. All the values refer to atmospheric pressure.—Dr. A. B. **Wood** and Dr. F. B. **Young**: (1) "Light-body" hydrophones and the directional properties of microphones. A light prolate ellipsoid possesses directional properties by virtue of its shape. Quantitative results obtained agree with calculated values supplied by Prof. Lamb. Owing to the pronounced intrinsic directional properties of the microphone, a spherical "light-body" hydrophone is practically equal in directional efficiency to one of ellipsoidal form. "Light-body" hydrophones are of value as experimental exploring instruments. (2) The acoustic disturbances produced by small bodies in plane waves transmitted through water, with special reference to the single-plate direction finder. Sound distribution was explored round a number of discs immersed at a distance from a small submerged source of sound. By means of a pair of miniature hydrophones—one bi-directional, the other non-directional—it was possible to chart (1) direction of oscillation of the water particles; (2) relative amplitude of the movements; and (3) relative amplitudes of the pressure oscillations. The charts obtained fall broadly into two classes, according as the discs are solid or contain air-filled cavities, very minute air-filled spaces giving marked effects. The behaviour of a typical baffle-plate is investigated, but no satisfactory theory of the baffle is offered.—M. A. **Giblett**: Some problems connected with evaporation from large expanses of water. The problems of distribution and amount of water-vapour present are considered for a current of air of uniform speed moving over a water-surface of uniform temperature. Near the surface is a thin layer of air, through which water-vapour diffuses slowly by molecular processes, but above this is a rapid transition to a turbulent *régime*, where diffusion becomes much more rapid. At and near the water-surface the problem is treated as one of eddy diffusion. Formulæ are obtained for humidity at any point of the air-current, and for rate of evaporation from stretches of water extending any distance down-wind. The distribution of water-vapour is obtained for some typical cases, and an estimate made of the rate of evaporation from long stretches of water under various conditions of wind, water-surface, temperature, and turbulence. The effects which each of these elements exerts, when varied within their natural range, are examined. The results emphasise the control exercised by atmospheric turbulence over evapora-

tion from large areas.—F. C. **Toy**: The photographic efficiency of heterogeneous light. Two possible laws of action are discussed:—(1) All radiations composing the heterogeneous beam may act simultaneously but independently; and (2) all radiations may act simultaneously but not independently. The possibility of testing the laws depends on the form of law connecting the probability of a single grain of the photographic emulsion being made developable with the intensity of the exciting light. The form of this law proved experimentally by Slade and Higson is considered, and a result is deduced which can be tested by experiment. From the evidence obtained it is concluded that over the spectral range used in the experiments (λ4350 to λ4000) radiations of different frequencies act simply as a total amount even when a difference in quality exists.

Linnean Society, June 2.—Dr. A. Smith Woodward, president, in the chair.—Prof. W. **Garstang**: Haeckel's biogenetic law: A theory of ancestral heredity. Ancestors created, heredity transmitted, and development repeated the order of creation. A generalised recapitulation of the essential grades of ancestral structure was also possible without involving successive adult images in the ontogeny. The morphological test to apply to these theories was whether the stages of ontogeny resemble successive adult organisations more closely than the corresponding formative stages of ancestral ontogeny. This test was invariably in favour of the "persistence theory" of recapitulation and against the theory of accelerated adult incorporations.

Aristotelian Society, June 6.—Prof. Dawes Hicks, vice-president, in the chair.—Dr. Dorothy **Wrinch**: The structure of scientific inquiry. In the earlier stages of empirical generalisations results of a general character are built up and applied by means of the forms of reasoning employed in probability inference, viz. induction and analogy. In the more advanced stage the aim of science is to arrange the general propositions which cover, as particular cases, the phenomena of which we are aware in such a way that the phenomena of the world are deducible from the smallest possible number of assumptions. Logical necessity alone can knit together theories and the experimental results which go with them. It is found that logic consists of relations between sets of properties. The general study of the formal and abstract properties is at the foundation of the great advance in modern science. In particular the process of *true analogy*, whereby the problems of electrostatics, current electricity, thermodynamics, and hydrodynamics are simultaneously solved, is of the utmost importance.

Paris.

Academy of Sciences, May 30.—M. Georges Lemoine in the chair.—A. **Blondel**: The application of distributed statical transformers to the regulation of high-voltage mains.—B. **Jekhowsky**: Bessel's functions with two variables.—E. **Kogbetliantz**: The developments of Jacobi.—Et. **Delassus**: A consequence of the laws of friction.—J. **Vallot**: Diffuse radiation at Mont Blanc Observatory compared with that at lower altitudes. The stations chosen were at the altitudes 50, 1100, 2500, 4250, and 4350 metres above the sea. A table is given showing mean values for the observations on several exceptionally fine days. The diffuse radiation diminishes at first up to an altitude of 2500 metres, and then at the top of Mont Blanc increases suddenly to nearly double. This is explained by the intense radiation of the snow.—A. **Schaumasse**: Observations of the Dubiago comet (1921*c*) made with the bent equatorial at the Observatory of Nice. Positions given for May 24 and 25. The comet was of the 11·5 magnitude, and showed a slight central condensation.—G. **Bruhat** and Mlle. M. **Hanot**: The Lippich black fringe and the precision of polarimetric measurements. From calculations and experiments cited it is concluded that even after choosing the best position of the line of separation it is not possible, with Nicol prisms, to measure a rotation of the order of 20° with an error less than one minute. With more intense sources of light, such as the mercury arc, this error can be reduced by one half.—R. **Boulouch**: The problem of achromatism of thick-centred systems.—M. **Rothé**: Radiogoniometry and atmospheric influences. Earlier observations (1914) had shown that in the course of the day Hertzian waves were absorbed by the atmosphere. The present research was an attempt to find out whether, in addition to absorption, the direction of the waves was modified. The deviations observed were of the order of the experimntal error, and consequently no certain conclusion could be drawn as to the cause of the small variations observed.—G. **Déjardin**: The ionisation of argon by slow electrons. An account of the application of the lamp with three electrodes, of the type commonly employed in military wireless telegraphy, to the determination of the ionisation potential of argon. The value found was 15 volts.—A. **Dauvillier**: The L series of uranium and the principle of combination in X-ray spectra.—A. **Cabrier**: An automatic lighting and extinguishing apparatus for street gas lamps. An account of an apparatus which has been in use for eight years, and comparison with a similar apparatus recently described by Paul Bernard and Barbe.—V. **Auger**: Double catalysis of vanadic acid and hydrogen peroxide. Vanadic acid may be reduced to vanadyl sulphate or oxidised to pervanadic acid by hydrogen peroxide in the presence of sulphuric acid, the direction of the change being conditioned by the amount of acid present.—Mlle. **Wolff**: Furfuralcamphor and some of its derivatives. An account of the product of condensation of furfural with camphor and the substances obtained by reduction.—M. **Manolesco**: The action of ethylmagnesium bromide on dibenzylidene *cyclo*hexanone and γ-methyl-*cyclo*hexanone.—G. **Tanret**: The influence of ammonium molybdate on the rotatory power of some sugars. Changes in the rotatory power produced by adding solutions of ammonium molybdate to solutions of xylose, glucose, rhamnose, arabinose, galactose, sorbose, lævulose, and mannose are given. No change was produced in the rotation of saccharose, maltose, trehalose, lactose, melezitose, raffinose, stachyose, inulin, quercite, and inosite. In the cases of the sugars whose rotation was affected, some evidence is adduced of the formation of a compound between the sugar and the molybdate.—F. **Bourion** and Ch. **Courtois**: The formation of Julin's chloride in the preparation of electrolytic chlorine. In certain cases acicular crystals were found in considerable quantities in electrolytic cells. These have been collected, purified, and shown to consist mainly of hexachlorobenzene.—F. **Roman** and P. **de Brun**: The structure of the Alpine chain.—Mlle. G. **Cousin**: The individual variations of *Psiloceras planorbis*.—M. **Flajolet**: The strong magnetic perturbation of May 14–15, 1921. An account of the magnetic disturbance as shown on the recording instruments at the Lyons Observatory. The needle was at times beyond the limits of registration, and all the telegraphic circuits were seriously affected.—G. **Dupont**: Contribution to the study of the acid constituents of the secretion of the maritime pine.

Lævopimaric acid is readily isomerised by heat, acetic, and hydrochloric acids, whilst the dextro-acid is unaffected. With hydrochloric acid the change is effected in two stages, first into α-pimarabietic acid, and this into the stable form, β-pimarabietic acid. The latter acid has been isolated and identified with the pure abietic acid isolated by Schultz.—N. A. **Barbieri**: Anatomical study on the aretinal termination of the optic nerve in the animal series. Results of anatomical analysis are given which, in the author's opinion, prove the complete and reciprocal independence of the retina and the optic nerve in animals. This would suggest the possibility of surgical intervention in the posterior chamber of the eye.—R. **Noel**: Some functional attitudes of the chondriome of the hepatic cell.—L. M. **Bétances**: Cells with eosinophil granulations of histioid origin in the blood circulating in the embryo.—C. **Gorini**: Sudden physiological mutations in lactic ferments by divergent individuals.—M. **Dervieux**: Method of individual diagnosis of the blood and of sperm. A serum is prepared by sensitising a rabbit by injections of human sperm. This serum gives precipitations with human sperm and human blood, and various applications in diagnosis are suggested. By its means it can be determined whether a given sample of blood is that of a man or a woman.—W. **Kopaczewski**: Food anaphylaxy and its therapeutics. In cases where horse flesh has been taken as food, or where infants have been nourished on the milk of the horse, exceptionally grave symptoms have been observed to follow the injection of antidiphtheric serum produced through the horse. It would appear to be probable that the body can be sensitised to a serum by food.—R. **Bayeux**: The use of oxygen mixed with carbon dioxide in subcutaneous injections, as a treatment of mountain sickness and certain toxic dyspnœia.—R. **Sazerac** and C. **Levaditi**: The action of bismuth on syphilis and on the Nagana trypanosome. Potassium tartarobismuthate exerts a marked curative action on experimental syphilis of the rabbit and on the spontaneous spirillosis of the same animal. The curative effects on Nagana trypanosomiasis, although clear, are inferior to the two above mentioned.

Books Received.

British Museum (Natural History). British Antarctic (*Terra Nova*) Expedition, 1910. Natural History Report. Zoology, vol. iii., No. 9, Insecta. Part i.: Collembola. By Prof. George H. Carpenter. Diary of Societies.

THURSDAY, JUNE 23.

ROYAL SOCIETY, at 4.30.—Dr. E. F. Armstrong and T. P. Hilditch: A Study of Catalytic Actions at Solid Surfaces. VI. Surface Area and Specific Nature of a Catalyst: Two Independent Factors controlling the Resultant Activity.—Sir J. B. Henderson: A Contribution to the Thermodynamical Theory of Explosions, Part I.; and (with Prof. H. R. Hassé) Part II.—S. Butterworth: Eddy Current Losses in Cylindrical Conductors, with Special Applications to the Alternating-current Resistances of Short Coils.—E. S. Bieler: The Currents induced in a Cable by the Passage of a Mass of Magnetic Material over it.—Dr. G. Barlow and Dr. H. B. Keene: The Experimental Analysis of Sound in Air and Water: Some Experiments towards a Sound Spectrum.—Dr. G. Barlow: The Theory of Analysis of an Electric Current by Periodic Interruption.

FRIDAY, JUNE 24.

PHYSICAL SOCIETY OF LONDON (at Imperial College of Science), at 5.—S. Butterworth: Capacity and Eddy-current Effects in Inductometers.—Dr. E. Griffiths: New Specific Heat Apparatus.—Prof. A. O. Rankine: Encounters between Non-spherical Gas Molecules.—Dr. C. Chree: An Electro-culture Problem.

MONDAY, JUNE 27.

ROYAL SOCIETY OF MEDICINE (Odontology Section), at 8.—K. Fry: The Dental Treatment of Congenital and Other Perforations of the Palate.

TUESDAY, JUNE 28.

ROYAL ANTHROPOLOGICAL INSTITUTE, at 8.15.—L. H. Dudley Buxton: The Ancient and Modern Inhabitants of Malta.

INSTITUTION OF CIVIL ENGINEERS (Engineering Conference), at 9.—Sir George T. Beilby: Fuel Problems of the Future (James Forrest Lecture).

WEDNESDAY, JUNE 29.

INSTITUTION OF CIVIL ENGINEERS (Engineering Conference), at 10 a.m.—The President: Opening of the Conference and Presentation of the John Fritz Medal to Sir Robert A. Hadfield, Bart.—A. Ross: The Structural Outlines of our Home Railways.—O. G. C. Drury: Tunnel Maintenance.—C. R. S. Kirkpatrick: To what Dimensions should Docks be Constructed to Provide for Future Requirements.—A. R. T. Woods: Ship and Harbour Design and Equipment as affecting the Rapid Loading and Discharging of Cargo Vessels.—H. J. Deane: The Development of Cranage Facilities for Discharging Vessels of the Largest Size.—G. FitzGibbon: Reinforced Concrete for Wharves and Breakwaters.—F. E. Wentworth-Sheilds: The Best Way of Protecting Reinforced Concrete from Marine Deterioration.—L. H. Savile: Reasons for the Deterioration of Reinforced-Concrete Structures above Mean Tide Level.—H. Lupton: Comparison between Reciprocating Pumping Engines and Turbo-driven Centrifugal Pumps.—E. R. Dolby: Exhaust Steam: its Employment for Power, Heating, etc.—J. W. Evans: The Employment of Water Power in the Development of the Mineral Industry.—R. Nelson: Recent Developments in Coal-cleaning Processes.—H. S. Ball: The François Cementation Process.—W. L. Roxburgh: The Necessity for and the Possibility of Development of the Coasting Trade.—E. G. Stewart: The Utilisation of Waste Heat in Gasworks.—Dr. J. S. G. Thomas: Desiderata in the Qualities of Town's Gas.—R. O. Kapp: Low Power-factor.

ROYAL SOCIETY OF ARTS, at 4.—Annual General Meeting.

THURSDAY, JUNE 30.

INSTITUTION OF CIVIL ENGINEERS (Engineering Conference), at 10 a.m.—W. W. Grierson: The Use of Reinforced Concrete on Railways.—H. J. Fereday: Impact Tests and Allowances.—A. H. Hall: The Influence of the Automatic and Semi-automatic Machine on the Skill and Resourcefulness of the Mechanic and Operator.—A. Musker: Mechanical Appliances and Labour in Loading and Unloading Ship's Cargoes.—Prof. W. E. Dalby: The Elastic Limit.—Prof. E. G. Coker: The Effect of Scratches in Materials.—C. P. Sandberg: Damage to Tires and Rails caused by Brakes or Slipping Wheels.—G. Hatton: The Existing Practice of Inspecting Work and Materials.—M. E. Denny: The Design of Fabricated Ships from the Labour-saving Point of View.—J. C. Telford: Economy of Labour on Shipbuilding as effected by Fabricated Ships, etc.—E. R. Mumford: Recent Tank Research in Screw Propellers.—E. H. Richards and M. G. Weekes: Straw Filters for Sewage-purification.—J. Haworth: Activated Sludge.—J. D. Watson: De-watering Sludge.—J. Dalziel: Battery Locomotives.

INSTITUTION OF MECHANICAL ENGINEERS, at 10.15 a.m.—Conference on the Means of Increasing the Thermal Efficiency of Heat Power Plants.

ROYAL SOCIETY, at 4.30.—*Probable Papers.*—Sir J. J. Dobbie and Dr. J. J. Fox: The Absorption of Light by Elements in a State of Vapour. The Halogens.—Prof. W. A. Bone and the Late W. A. Haward: Gaseous Combustion at High Pressures. Part II. The Explosion of Hydrogen-Air and Carbon-monoxide-Air Mixtures.—Prof. A. E. H. Love and F. B. Pidduck: Lagrange's Ballistic Problem.—J. Proudman: The Principles of Internal Ballistics.—R. H. Fowler: A Simple Extension of Fourier's Integral Theorem and Some Physical Applications in particular to the Theory of Quanta.—Capt. D. Brunt: The Dynamics of Revolving Fluid on a Rotating Earth; and other papers.—The following papers will be read in title:—Takeo Shimizu: A Preliminary Note on Branched α-ray Tracks.—Takeo Shimizu: A Reciprocating Expansion Apparatus for detecting Ionising Rays.—Prof. R. W. Wood: The Time Interval between Absorption and Emission of Light in Fluorescence.

FRIDAY, JULY 1.

INSTITUTION OF CIVIL ENGINEERS (Engineering Conference), at 10 a.m.—R. G. H. Clements: Road Vehicles and their Relation to Road Surfaces.—A. Dryland: Advantages of Bituminous Macadam.—C. H. J. Clayton: The Conservancy and Maintenance of Rivers from the Point of View of Land Drainage.—R. F. Grantham: The Effect of Sluices and Barrages on the Discharge of Tidal Rivers.—G. E. W. Cruttwell: The Utility of Models for Estuarial Experiments.—H. C. Reid: The Relative Advantages of Dredging and Training-walls in Estuaries.—E. Latham: The Use of Inertia Gauges in Pile Driving.—A. L. Bell: The Bearing Power of Soils.—Sir James McKechnie: Internal-combustion Engines with Large Cylinders.—Sir Vincent L. Raven: The Mechanical Advantages of Electric Locomotives compared with Steam.—T. Crook: The Effect of the War on Mineral Supplies.—M. Deacon: The Utilisation of Exhaust Steam in Turbines.—W. C. Mountain: Steam *versus* Electric Winding.—S. Cowper-Coles: The Relative Values of Protective Metallic Coatings for Iron and Steel.—J. Richardson: Recent Progress in Large Diesel Engines for the Mercantile Marine.—R. J. Walker and S. S. Cook: Experience with Marine Turbine Reduction-gears.—E. Sandeman: Compensation Water.—F. W. Macaulay: Pipes for Pressure Conduits.—Dr. H. Lapworth: The Relation of Run-off to Rainfall.—Economic Limits of Distribution from Coal-fired Stations.—B. Welbourn: Low-voltage Overhead Distribution.

INSTITUTION OF MECHANICAL ENGINEERS, at 10.30 a.m.—Conference on the Means of Increasing the Thermal Efficiency of Heat Power Plants.

American and British Superannuation Systems.

THE fifteenth annual report of the president and of the treasurer of the Carnegie Foundation for the Advancement of Teaching provides some interesting reading, particularly with regard to the pension system in operation in the universities and colleges of the United States. The work of the Foundation falls into three parts: (1) the completion and liquidation of the old system of full-paid pensions; (2) the development of the contractual forms of insurance and of old-age annuities through the policies of the Teachers' Insurance and Annuity Association; and (3) the prosecution of significant studies and reports through the Division of Educational Inquiry. The last-named constitutes an important and active branch of the Foundation, with an income derived from the investment of a capital of one and a quarter million dollars. Its most recent inquiries relate to the subjects of legal education and the training of teachers. As a result, "A Study of the Training of Teachers for the Public Schools" has recently been published, and there is promised in the immediate future the first section of a "Study of Legal Education." Without doubt, such inquiries form an increasingly valuable feature of the work of the Foundation.

On the other hand, it is to be noted that the trustees administer a total sum of almost twenty-five million dollars, the income from which is at present mainly devoted to superannuation purposes. For the year ending June 30, 1920, the sum of 875,514 dollars was granted in retiring allowances to administrative officers and teachers or their widows in certain of the colleges and universities in America. As is well known, the gift was intended primarily to establish retiring allowances for teachers in the higher institutions of learning in the United States, Canada, and Newfoundland. The income was, however, quite insufficient to provide for all these, and at present the pension obligations of the Foundation are confined to some five or six thousand teachers and administrative officers who were in the service of institutions associated with the Carnegie Foundation on November 17, 1915. As the income is released, it will be devoted to the advancement of teaching in American colleges and universities.

With regard to the officers and teachers who do not participate in these pensions—the large majority—the trustees have promoted a contractual plan of old-age annuities, and some fifty pages of the report give an account of its progress and development. In brief, it is a contributory system of deferred annuities which will gradually supersede the previous non-contributory pension scheme. It is intended that the teacher should contribute 5 per cent. of his salary, and the institutions a like sum, the combined premium to be paid to the Teachers' Insurance and Annuity Association and to become the property of the association. In exchange the teacher will receive an annuity policy—a contract which guarantees that in case he dies before the stated age a sum equal to the premiums with interest will be paid to his dependents, and that in case he lives to the stated age a selected annuity of equivalent value will be paid. It will be observed that insurance is considered a responsibility of the teacher alone. The success of the scheme so far may be measured by the fact that the association, which began the issuing of contracts in March, 1919, had, by July, 1920, issued policies representing more than two and a half million dollars insurance, and also annuities representing the payment at maturity of nearly half a million dollars annually.

It is instructive to compare this scheme with the Federated Superannuation System of British universities. In the first place, some five or six thousand American teachers who were in service in the associated institutions before November 17, 1915, are well provided for by the Foundation by means of a non-contributory scheme for which there is no parallel in the British scheme. The nearest approach to this splendid provision is the

recent Government grant of 500,000*l.*—a sum, however, which is less than half what is required to put the pensions of the senior members of the university staffs upon a satisfactory footing. In addition, the Carnegie Foundation will continue to provide retiring allowances on the same non-contributory basis to a certain number of old and distinguished teachers. Next, in the British system there is no specific provision for widows or orphans, nor is there provision for disability such as has been instituted by the Carnegie Foundation "for the teacher who, despite his own foresight and self-denial, finds himself and his family the victims of disease or of accident." The reserve accumulated to meet such claims is now 220,000 dollars.

Further, the American scheme is administered from within, as opposed to the Federated System, which is worked through insurance companies. In consequence, there is economy in administrative and other expenses. Insurance companies are not philanthropic institutions. Mr. Fisher, President of the Board of Education, on the second reading of the School Teachers (Superannuation) Bill, 1918, was aware of this when he stated that if the Act were worked through insurance companies there would be the objection that public money was going in dividends to the shareholders of these companies. This is precisely what is happening in the Federated Superannuation System to-day. The Teachers' Insurance and Annuity Association furnishes policies better suited to the teacher's needs, and at lower cost, than companies operating on a commercial basis.

The report contains a mass of interesting matter relating to pensions and pension schemes, including arguments, by no means convincing, in favour of contributory schemes as opposed to non-contributory.

Lord Rayleigh's Scientific Papers.

Scientific Papers. By Prof. John William Strutt. Vol. vi., 1911–19. Pp. xvi+718. (Cambridge: At the University Press, 1920.) 50*s.* net.

THE sixth[1] volume of Lord Rayleigh's collected works, just issued by the Cambridge University Press, contains his papers, nearly one hundred in number, published between 1911 and his death in 1919. In fact, the last two papers, Nos. 445 and 446, of the whole series were left ready for publication, but had not appeared when he died, while the concluding paragraphs of No. 444, on "The Travelling Cyclone," were dictated by him only five days before his death on June 30. He was happy in being able to continue his work until so near the end, and in his fifty years of active scientific life to achieve so much.

The papers in the volume range over a wide list of subjects, and while none of them have the importance of some of those appearing in earlier volumes—*e.g.* the series on the fundamental units of electrical measurements, or the publications describing his work on gases and the discovery of argon—they are marked, as ever, by his power of clear thinking, his grasp of first principles, and his ability to appreciate the essentials of any problem which appealed to him. Some three or four of the articles were contributed to the discussions of the Advisory Committee for Aeronautics, over which he presided for ten years. Among these may be specially mentioned No. 389, the note on the formula for the gradient wind, in which the formula connecting the velocity of the wind, the barometric pressure, the latitude, and the rotation of the earth, which had been employed by Gold and other meteorologists, is derived, assuming the motion in two dimensions, from hydrodynamical principles. The paper No. 444, already mentioned, on "The Travelling Cyclone," though not formally communicated to the Committee, arose out of its discussions.

There are also some notes and reviews communicated to NATURE, but most of the other articles appeared in the *Philosophical Magazine*. Hydrodynamics, optics, and acoustics form the subject-matter of many—problems of vibrations in the solution of which the methods developed in the theory of sound or in some of his earlier optical work are employed with success. Of recent years he returned to a number of optical problems which in earlier days had interested him, and advanced our knowledge by his work. Among these papers may be mentioned several on the scattering of light by small particles. The problem was discussed in the well-known paper on "The Blue of the Sky," published in 1871, and in 1918 Lord Rayleigh gave the complete solution for a sphere in which the structure is symmetrical, but periodically variable, along the radius, while a further paper—*Phil. Mag.*, vol. xxxv.—discussed the case of the scattering of light by a cloud of similar small particles of any shape oriented at random. He was led to investigate the question by the results of his eldest son's experiments on light scattered by carefully filtered gases.

[1] A notice of vol. v. appeared in NATURE for October 28, 1913. The other volumes were reviewed at an earlier date.

One of the papers communicated to the Advisory Committee for Aeronautics deals with the analogy between the conduction of heat from a surface and the transfer of momentum in a viscous fluid flowing over the surface. Lord Rayleigh shows that the analogy, which holds so long as the motion is laminar, breaks down when it becomes turbulent. A letter to Prof. Nernst, dated October, 1911, is of rather special interest, though there is nothing in the later pages of the volume to indicate whether or not Lord Rayleigh continued to hold the same opinion to the end. He is discussing some of the difficulties which attend the kinetic theory of gases, and writes :—

"Perhaps this failure might be invoked in support of the views of Planck and his school that the laws of dynamics (as hitherto understood) cannot be applied to the smallest parts of bodies. But I must confess that I do not like this solution of the puzzle. Of course, I have nothing to say against following out the consequences of the [quantum] theory of energy—a procedure which has already, in the hands of able men, led to some interesting conclusions. But I have a difficulty in accepting it as a picture of what actually takes place."

A paper in the *Philosophical Magazine* for 1919 of somewhat greater length than the majority of those in the present volume deals with the optical character of some brilliant animal colours. The question whether the colours displayed by various birds, by butterflies, and by beetles are structure colours more or less like those of thin plates or are due to surface or quasi-metallic reflection is discussed, and the conclusion reached by Lord Rayleigh is thus stated :—

"The impression left on my mind is that the phenomena cannot plausibly be explained as due to surface colour, which in my experience is always less saturated than the transmission colour, and that, on the other hand, the interference theory presents no particular difficulty unless it be that of finding sufficient room within the thickness of the cuticle."

In the paper a reference is made to the drawings and conclusions of the Hon. H. Onslow, some of which have since been published.

It is not necessary to add more, or to attempt to give a full account of the contents of the volume under review; there is interest to be found in every page, and throughout it is marked by the characteristics of Lord Rayleigh's writings. He is to be commemorated by a tablet and inscription in the Abbey; the six volumes of his collected works form his true memorial, built by himself, to live so long as there are students of physical science to read and learn the truths which they contain.

The volume has been edited by his son, the present Lord Rayleigh, with the help of Mr. W. F. Sedgwick. It is published by the Cambridge University Press in its usual admirable style, and concludes with a classified table of contents of the whole of the six volumes. The list, occupying some forty pages, shows in a remarkable way the extent of ground covered by Lord Rayleigh's contributions to physical science.

Studies of British Mammals.

Habits and Characters of British Wild Animals. By H. Mortimer Batten. Pp. 346. (London and Edinburgh: W. and R. Chambers, Ltd., 1920.) 21*s*. net.

THERE are several trustworthy and readily available books on British mammals, such as Lydekker's and Sir H. H. Johnston's, not to speak of the expensive volumes of Millais and others, but there is a distinctiveness in Mr. Mortimer Batten's studies which makes them welcome. They have a broad basis of personal observation, they give prominence to habits, and they try to get at the character of the creatures. The book is written in excellent style; it smacks of the open country, and it is packed with interesting information without being overloaded. The very artistic illustrations by Mr. Warwick Reynolds appeal to us as revealing the temperament of the animals portrayed and also as pictures, *e.g.* the charming coloured frontispiece of roe-deer jumping up at rowan berries.

Mr. Mortimer Batten deals with red deer, roe-deer, fox, weasel, stoat, otter, pine-marten, badger, polecat, brown hare, mountain hare, rabbit, hedgehog, squirrel, brown rat, water-vole, and wild cat. Without rigidly adhering to any scheme, he discusses range, feeding habits, breeding, struggle for existence, interrelations, general characteristics, size, weight, and last, not least, the disposition or character. We wish that, when he was at it, he had completed his survey of British mammals so that his excellent book might have been a comprehensive unity. A second edition should remedy this. We do not mean that there need be any treatment of the Orkney vole and that sort of thing, but we miss the little gentleman in the velvet coat; we should like to have seen the book representative of all the short list of British mammals. We must protest, of course, against the usage which calls this a book on British wild *animals*.

We have found Mr. Mortimer Batten's studies full of interest, and we have a lively appreciation of their originality and independence. Sometimes, we confess, his theoretical interpretations

make us pause, *e.g.* the suggestion (after rejecting all others known to the author) that the biological significance of the stag's antlers is to divert the attention of enemies from the hinds. Sometimes we wish the author had been a little more bookish, for his remarks on the correlation between antlers and reproductive organs are far from being up to date. We are sorry that he has no contribution to make to our knowledge of the method of the ermine's assumption of its white dress, the precise mode of which seems still uncertain. Was Prof. MacGillivray right or Mr. Aplin, or were both right? Sometimes the author's generalisations pull us up with a start: "There is no logic in the ways of Nature." But we thought that Darwin proved there was! The fact is that Mr. Mortimer Batten is stronger on the side of natural history than on the side of biology. He rather scoffs at the protective value of the whiteness of the mountain hare in winter, but he does not mention the other utilitarian interpretation—in relation to body-temperature. He says of the common hare: "Wherein lies the secret of the hare's survival? In its fecundity, and there alone." Yet the preceding pages make it perfectly clear that this is not the case. Again, to take a more concrete point, it is surely in a metaphorical sense only that we can speak of the hedgehog's fat serving "as sustenance during the foodless days of sleep." It is interesting to notice that the author occupies a Lamarckian position as regards the mental endowment of the subjects of his studies:—"All these things the water-voles of to-day do not, probably, reason out for themselves; the knowledge of them has been inherited from countless generations of forefathers who, atom by atom, grain by grain, have profited by their experience, and, acting accordingly, have handed their lessons on to their children, thus establishing such life habits and customs of the species that we have to-day a water-vole that can hold its own." But we are afraid there is no plane-sailing for this theory.

We have often thought that great benefit might result to science if a field-naturalist like Mr. Mortimer Batten were to test biological theories in the light of the everyday life of the creatures he knows. If, however, this is to be of avail, the field-naturalist must first sit at the feet of the biologists, and he will not do this because they do not know a badger's track. Thus the possibilities of a mutually profitable partnership are lost. We must not forget, however, that this book was meant, not for biologists, but for ordinary folk interested in the country, especially for those who can understand and sympathise with the author's plea for the pine-marten. To such the book is strongly to be recommended. It is first-hand material, vividly presented, abounding in picturesque and essential detail, and making a resolute attempt to see each of these wild mammals as an individuality with a character and temperament of its own.

Forestry in France.

Studies in French Forestry. By T. S. Woolsey, jun. With two chapters by W. B. Greeley. Pp. xxvi+550. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 36*s.* net.

MR. T. S. WOOLSEY, who is well known as an expert in and an authoritative writer on forestry, has given to American and British foresters in his "Studies in French Forestry" a means of gaining a deep insight into the theory and practice of forestry in France. The material for the present book was collected largely in 1912, but administrative work at home and service with the U.S. Corps of Engineers during the war prevented earlier publication. That is, we think, a fortunate thing, because the author has been able to include much information regarding the wonderful organisation of the French Forestry Service and the Allied Forestry Corps in maintaining an adequate supply of timber. Many forests had to be clear-felled, and others were so depleted of growing stock that "normal" production cannot be secured for a century or more. There are more than a million acres of French soil to be restored to productivity, and the rehabilitation of innumerable forests—300,000 acres—the growing stocks of which have been cleared or seriously depleted, must be brought about by the strictest economy at a time when the economic demands for wood products will be at least double the normal consumption.

The attitude of public opinion in France in regard to the *rôle* of the forest in national economics is reflected in the extremely stringent regulations contained in the National Forest Code. The common law alone is regarded as inadequate for the protection of forests in France; therefore the special forest code provides not only against wilful damage, but also against damage due to carelessness or ignorance in dealing with forests and forest lands. Still, it is not by these means that France has established her State, communal, and privately owned forests. She has in actual practice relied more on methods of example and co-operation in building up and establishing for all time her excellent forest reserves and systems of management.

The influence of the forest or its indirect value

is a matter of great importance from national, economic, and æsthetic points of view, yet this phase of forest utility is only too often ignored. In a short but interesting chapter the author has succeeded in summarising the main facts and focussing them in an admirably lucid manner.

In the succeeding chapter the forest regions of France and the important tree species are described. An interesting review is given of the area, topography, and prevailing climatic conditions of France, and striking illustrations are given of the recent wonderful development of the natural resources of the country in hydraulic power. Further on are presented the forest statistical data, which bring out many points of absorbing interest. One striking fact is that the number of small forest owners is incredibly large. The small owner of less than 25 acres of forest is greatly in the majority, but the proportion of sawn timber to fuel wood in State-owned or technically managed forests is much more advantageous than in those privately owned.

The natural and artificial regeneration of forests, as practised in France, is well worth the close attention of students of sylviculture. An excellent account is also given of the control by afforestation of mountain torrents and lowland floods, which in the past have caused privation and ruin to thousands of the population, and untold loss to the nation.

The author also gives a most interesting account—historical, statistical, and technical—of the wonderful forests of the Landes. The almost magical transformation of a barren, fever-stricken waste of something like two million acres into a healthy and prosperous revenue-yielding territory, to the enormous advantage of France and every individual Frenchman, was a marvellous achievement. The State, as the author puts it, "blazed the trail," the good lead was followed by the "communes," and private effort did the rest. Much useful information is given concerning French Government regulations and working plans, the features of French national forest administration, and private forestry in France.

An interesting account is given of the activities of the Forest Engineers in France. The vital importance of timber in modern warfare is shown in many ways, and it is safe to conclude that without the well-planned forests and timber resources of France "the war might have been a draw or a defeat instead of a victory."

A number of interesting appendices are added which deal with specific forestry subjects, including an exhaustive list of French forestry literature, and there is a good index. The book is well illustrated with photographs and diagrams.

Our Bookshelf.

Official Statistics. By Prof. A. L. Bowley. (The World of To-day.) Pp. 63. (London: Humphrey Milford: Oxford University Press, 1921.) 2*s.* 6*d.*

A LITTLE book on statistics by so well-known an authority as Prof. Bowley is sure of a welcome from the educated public. In these times, when copious reports are issued by many Government departments, it is not only interesting, but also necessary, to appreciate fully the significance and limitations of official statistics. This is admittedly difficult, and it is with the view of steering the uninitiated through the mass of detail which necessarily obscures the real value of statistical information that Prof. Bowley has written this little book. A brief account is given of the more important reports and papers published officially in recent years containing statistics of general interest. The use of reports is illustrated by collecting details scattered throughout such a volume as the Report on Pauperism and retabulating them so as to show how the various tables are connected. In all cases exact references have been given to the original documents. The scope of the volume is well indicated by the chapter headings, four in number: population; industry, trade, and prices; income and wages; and social conditions.

A Laboratory Manual of Organic Chemistry for Medical Students. By Prof. M. Steel. Second edition. Pp. xi+284. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 9*s.* 6*d.* net.

A CHAPTER on colloids which contains some interesting experiments forms the principal addition to this edition. Many careless expressions have been overlooked: "fused" copper sulphate and "fused" calcium oxide are not common reagents, and "hydroscopic" (p. 32) appears instead of "hygroscopic." Moreover, some of the directions for experiments do not seem to be based on trials, *e.g.* the preparation of acetylene would be dangerous if carried out as described on pp. 19–20, for air could not be displaced from the apparatus under the conditions named; also the directions given for the preparation of colloidal platinum on p. 220 do not seem correct—it would be difficult to pass a current of 10 amperes through distilled water by applying only 40 volts.

Ammonia and the Nitrides: With Special Reference to their Synthesis. By Dr. E. B. Maxted. Pp. viii+116. (London: J. and A. Churchill, 1921.) 7*s.* 6*d.* net.

THIS small volume contains an account of laboratory investigations of the nitrides of the elements. No mention is, however, made of the very important industrial applications of the results except in the case of the Serpek process, which is not in use in the form described by the author. "Deville," on p. 37, should be "Regnault."

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Co-operative Indexing of Periodical Literature.

The following remarks refer to the periodical literature of science alone. The present lack of system in indexing this leads, we all know, to a huge waste of energy. If this could be saved by intelligent co-operation it might be set free for more profitable work. The leading article in Nature of June 9 may help towards this both by the information that it gives and by that which it may elicit. For example, it recognises that a necessary preliminary is a survey of the periodicals in the libraries, and it states that for the United Kingdom such a survey was prepared in 1914–15 and is in MS. at the British Museum. This can scarcely have been within the knowledge of the Conjoint Board of Scientific Societies when it issued a recent appeal for this information to the scientific libraries of London, nor can it have been known to the Zoological Record Committee of the Zoological Society when it still more recently instructed its editor to make a similar survey for its own purposes. If Nature can help forward the publication of a complete survey it will do good service.

The next step, so far as this country is concerned, will be to fill up gaps and to render all the periodical literature of any consequence accessible to the indexers. Your article does not touch on this, but it is surely more important for us that a paper should be accessible than that an index-slip for it should be sent from Bulgaria or Bolivia.

You consider the publication of abstracts before that of the index to be indefensible. This is not clear. It is possible to publish an abstract at the same time as (or even before) the original paper; the abstract is complete in itself, and, since it is in the nature of news, the sooner it is distributed the better. The index-slips can also be issued at the same time; but they have little meaning until arranged in an index, and the more complete the index is, and the larger (within limits) the period it covers, the better. Consequently, the index volume falls to be published later than the abstracts. The index material is of no use to the abstractor, and the indexer should not work from an abstract. Index and abstract are different in aim, in substance, and in mode of preparation. Their sole connection is that they deal with the same material, and both demand that material to be accessible. We return then to the primary need of completing our libraries as the best way of helping both parties.

This conclusion is opposed to your other suggestion, that the best way, so far as science is concerned, is to get index-slips from the Central Bureau of the International Catalogue of Scientific Literature. If this means a return to the attempt at furnishing slips through a number of national bureaux, it may be dismissed as discredited and now less workable than ever. If it means that the Central Bureau is to embark on all the work of collecting the literature, analysing it, and preparing the slips, may one ask if the proposer has considered whence the staff, offices, and funds are to be obtained?

Finally, what is the use of a *general* conference to determine the requirements of *special* branches of knowledge? Let each branch of science look after its own abstracts and indexes. Probably this would best be done by the leading societies, as for some sciences it already is. Any society taking the lead in its own branch should receive ungrudging aid from the others who are not so ready to shoulder the burden. Let general international help be concentrated on supplying the first essential, namely, the publications that are to be indexed. And so we are back where we started—at the foundation that has to be laid firmly and broadly.

F. A. Bather.

June 11.

In considering the future of indexing, must not the method of indexing and abstracting depend on the purpose and future utility of abstracts? Do we want the means of manufacturing footnotes by unlimited references, or a guide in research? If for research, does a worker wish—or have time—to look up every reference, or does he want to get the sense of what has been done that will affect him? Can all classes of subjects be treated usefully on a uniform system, or is there any reason for doing so? Can a discrimination be expressed between papers that advance a subject, by new facts or new arrangements, and those that are inconclusive? Should an abstractor be entirely mechanical, or should any criticism be allowed?

A small experience in one department, of abstracting the produce of some twenty foreign periodicals (special and general) with a view to future utility, has led me to adopt the following standard:—

(1) State briefly every new fact and argument that leads to a definite result.

(2) Add references to any confirmatory or contradictory facts that have been omitted.

(3) Suggest if the paper is essential.

Such abstracts should be indexed at suitable intervals.

Some such standard seems likely to be the most useful for present reading and future research, in some subjects. How far would such a standard be desirable or applicable to different subjects? How far can individuals be found to make themselves responsible for dealing with their own special branch?

Too often, after struggling through thorn-brakes of German, or seas of Italian diffuseness, one emerges at the same point again, and finds that the whole is a rhetorical exercise. Should not workers be protected from such writing? Think of the future, with another century of accumulated writing, even at the present rate.

W. M. Flinders Petrie.

I am in entire sympathy with the leading article in Nature of June 9 on the subject of the co-operative indexing of scientific communications to periodicals. If, however, any scheme is to be carried out efficiently competent workers must be employed, and they must be adequately paid, which is no easy matter in these days.

I cannot, however, subscribe on the scientific side to the assumption that there is any considerable amount of periodical literature consisting of "water-tight compartments containing homogeneous material" presenting "no special difficulties" in indexing. The different sciences are becoming more and more interdependent. For example, geological investigators are continually in need of results obtained in other spheres of work, such as chemistry, physics, astronomy, geodetics, botany, and zoology. Numerous facts important to geologists also occur scattered through technical mining publications. It is important that all these fields should be gleaned in the interests of

geology, as well as the common land of general periodical literature. The index of advances in physics required by a geologist will differ materially from that which meets the needs of a physicist.

JOHN W. EVANS.

Imperial College, South Kensington, June 12.

IN the very interesting and important leader of your issue of June 9, dealing with the co-operative indexing of periodical literature, attention is mainly confined to the natural sciences, but whatever is said as to the necessity for some new co-operative effort there in order to render more accessible the contributions in what you call the non-homogeneous class of periodicals, the need is even greater in another field of knowledge. May I venture to point out that in the field of one of the political sciences, if history and its allied subjects can be included in such a term, co-operation is even more urgently needed, and may be profitably undertaken along similar lines and in close concert? In very few fields of historical investigation do workers possess the advantages that are afforded by comprehensive bibliographies of recent publications, and practically nowhere are there to be found abstracts such as are familiar to their colleagues in chemistry, physics, and other natural sciences. The "Lists of Writings on American History" that have been published since 1902 under the auspices of the American Historical Association, and the bibliography of "Publications relating to the History of Canada," published at Toronto, show that it is entirely practicable to undertake such work with success. At the approaching conference of Anglo-American Historians, to be held in the University of London on July 11–16, various schemes for co-operative effort are to be considered, and among them may possibly be projects for co-operative lists of periodical publications. It is hoped by many of those who are taking part in the conference that some concrete results will arise from these discussions. May I, therefore, suggest that when any steps are taken to summon a conference such as you propose for the extension of the bibliographical equipment of the sciences opportunities should be afforded to the historians to take part? It would be an inestimable boon if the principle of co-operative and co-ordinated action on common lines could be extended as widely as possible in the fields where the scientific method can be profitably employed.

ARTHUR PERCIVAL NEWTON.

University of London, King's College,
June 18.

I HAVE read with great interest the leading article on "Co-operative Indexing of Periodical Literature" in NATURE of June 9.

I have never been concerned with any work involving indexing of scientific periodicals, and those which have been my business, dealing with the classics, Oriental subjects, and bibliography, are essentially of the "watertight" character which present a much less serious problem to the student.

I think, however, there is one class of publication to which I should direct attention in connection with the subject of indexing for the use of present and future students, namely, official publications (Parliamentary papers, Stationery Office publications, reports of committees, etc.), which contain a great quantity of material which must necessarily be of value to investigators in various lines of research, and the lack of a clue to them is serious, especially as they are, from their quasi-anonymous nature, difficult to discover in the ordinary library catalogue.

If any conference such as that suggested in your article were called, I hope it would consider the indexing of these as well as of periodicals in the strict sense of the word. I do not think that any endowment will be forthcoming from public funds, but librarians in Government Departments and other Civil Servants with bibliographical interests would probably be willing to help in the work of compilation. I should certainly be prepared to make myself responsible for slips analysing the papers laid before Parliament by the Foreign Office.

June 11. STEPHEN GASELEE.

W. Warde Fowler: A Personal Appreciation.

ALL who know his "Tales of the Birds" will deplore the loss of this gifted observer and writer. My review—three and a half pages long!—of his charming booklet, "An Oxford Correspondence of 1903," under the title "Oxford on the Up Grade," in NATURE, June 16, 1904, was the beginning of an all too infrequent correspondence. He was good enough to write that I had entered into the spirit of his views more than any other critic. They certainly appealed to me at the time; and to-day, when mere memorising and over-examination—including psycho-analysis—are becoming more and more of a curse and subversive of all mental progress, they merit the most careful consideration. Warde Fowler had cast off the blinkers worn usually by the literary man and could see widely. He could console his pupil's father for the son's failure in the I.C.S. examination by saying, "Never mind; he will do good work in life as soon as he recovers from the effects of his education."

In a postscript to his last letter to Jim Holmes, his young correspondent, he remarks:—

> I agree with what you said in your last letter about Greats. We had better grow our own plants instead of introducing exotics; but we must take care that our own plants get a real chance of coming to perfection.

Here the Oxford position is stated in a sentence; but the newer Universities are still more open to the implied criticism—as in all of them far too many things are attempted and the plants consequently are of stunted growth. In the interval, there has been advance at Oxford but not on an even grade; and the beer-point of enthusiasm (see my review) is not yet reached. So ineffective is the influence of its environment, that a professor, who over a long period had shut up the instruments of research in glass cases, into whose lap a great fortune had been dropped, could die recently without benefit to the University.

Take, too, his interesting quotation from Roger Ascham's "Scholemaster":—

> "All soch Authors as be fullest of good matter and right judgement in doctrine be likewise always most proper in wordes, most apte in sentence, *most plain and pure in uttering the same.*"

On this he makes the comment:—

> If I am not mistaken, this would have delighted Darwin.

This is not only a just recognition of Darwin's literary gift but should serve to confound Sir A. Quiller Couch and all those who presume to scoff at the literary shortcomings of scientific workers—without recognising how few literary men can be plain or pure in their utterance and how few either have

matter to write about—rarely anything novel—or can produce doctrine worth consideration. Usually they are but dealers in hashed mutton; they may spice it pleasantly but it is still hash. "It is astonishing what nonsense able men will sometimes write, just because they don't know even the elementary laws of scientific investigation," said Warde Fowler.

I have a letter of his before me, from Kingham, Chipping Norton, dated July, 1913, acknowledging a pamphlet on Nature Study which I had sent to him:—

> I must confess (he writes) to an innate aversion from "Nature Study" in inverted commas and capital letters, *i.e.* as practised in too many schools, because I know that the teachers are quite ready to "teach" what they don't understand a bit and that the only person who can really help the children in these things is one who is learning himself all the time and learning not only from books but using them just as a help. I am very glad to see that you have the same kind of feeling.

Then he speaks of his work in the village school:—

> This week, for example, I have given away two copies of my recent book on this village (which is sought after in the village) as prizes for accounts of the growth of corn (which is growing all around us in different stages) from the seed to the fruit, with specimens. Two girls won the prizes and there were some dozen good answers. The boys seemed more interested in the processes of agriculture than in the growth of the plant and the boys are fewer in number than the girls. I myself have learnt much that I did not know before and so has the schoolmaster. They were all silent or in difficulties about the bloom of the corn and no wonder. What a number of beautiful and interesting things there are to be learnt about it. To-day I have been learning something about the corn smut and turned out a book about diseases of cereals which I had hardly opened since I wrote my "Roman Festivals" and wanted to know something about the róbigo, for the Festival of Mildew (Robigalia). One wants a microscope, however, to interest children in such things as that.
>
> I feel as if I should like to go on talking to you but I must be content with thanking you for your reminiscence of my young friend Jim Holmes, for whom I still have a sneaking fondness, as the only (or almost the only) creature of my brain.

In the "Roman Festivals," a work of marvellous erudition and research, he devotes quite a long section to the discussion of the Robigalia and remarks that "the red mildew was at times so terrible a scourge that the Robigalia (April 25) must in early Rome, when the population lived on corn grown near the city, have been a festival of very real meaning. A red dog was sacrificed to Robigus, the spirit who works in mildew. Nowadays nothing that happens in agriculture is marked by sacrifice."

Whether we think of Warde Fowler as literary man or naturalist, however, for the man who could write:—

> I will tell you that the joy of discovering something that you did not know before is in my experience very great and that the joy of finding that so far as your knowledge goes no one ever found it out before is far greater,

we shall long keep a place in our memory. Oxford will best serve his memory by increasing the number who can have that joy, as to-day, it may be feared, we are farther off than we ever were from that "general and vehement spirit of search in the air," which Lord Morley long ago proclaimed to be our prime need: not a few schools, too, are aiming at a classical revival; the meaning of science is not yet with them generally.

H. E. A.

Ionisation Potential and the Size of the Atom.

IT is known that there is for different elements a relation between the ionising potential and atomic volume, the one increasing as the other diminishes. Hughes in his book on "Photo-electricity" (p. 51) indicates that the work in removing an electron wholly from an atom might be expected to vary inversely as the radius. In other words, the ionising potential might be inversely proportional to the cube-root of the atomic volume.

Now W. L. Bragg, in the *Philosophical Magazine* (August, 1920), has given the diameters of atoms in Ångstrom units (10^{-8}cm.), on the assumption of close packing in crystal structure. The diameter which he determines is more strictly the distance from centre to centre of contiguous atoms of the same kind. The dimensions which he thus found are far smaller than those deduced from calculations by kinetic theory.

It appears desirable to make a comparison of the ionisation potentials (1) with the diameters as given by W. L. Bragg, and (2) with the cube-root of the atomic volume.

In the subjoined table the name of the element, the ionisation potential, and Bragg's diameter ($\times 10^8$), are set forth in the first three columns. The product of the diameter and ionising potential appear in the fourth column. The cube-root of the atomic volume is stated in the fifth column, and its product with the ionisation potential in the sixth column.

I. Element	II. Ionisation potential	III. Diameter $\times 10^8$	IV. II. × III.	V. Cube root of atomic volume	VI. II. × V.

In the first group of the periodic table the products shown in each of the fourth and sixth columns of the above table are fairly concordant, so that we may conclude that the work done in the removal of an exterior electron is nearly proportional inversely as the radius.

The same remark applies to four elements of the second group, while the members of sub-group B diverge considerably from the values for the A group. According to Urbach (*Phys. Zeit.*, February, 1921, p. 116), the elements of the B sub-group have a double ring of electrons in the outer zone, while those of the A sub-group have a single ring. In the case of the inert gases, neon and argon, the diameters estimated by Bragg give products in the fourth column in far better accord with theory than those found from the cube-root of the atomic volume set forth in the sixth column.

The values for certain elements in groups iii.–vii. are given in the table for comparison, but our knowledge of ionising potentials is as yet too fragmentary to permit of any definite conclusions.

The ultimate solution of this problem may involve calculations of the character given by Sir J. J. Thomson in his recent paper in the *Philosophical Magazine* (March, 1921, p. 526).

I am indebted to Prof. A. Ll. Hughes for his assistance in endeavouring to collect the most trustworthy values for the ionising potentials.

A Novel Magneto-Optical Effect.

THE interesting observation recorded by Prof. Elihu Thomson in NATURE of June 23, p. 520, seems likely to have a bearing on the old Reichenbach experiments, which were for the most part disbelieved by orthodox science, but on which Sir William Barrett and others made some careful observations, to ascertain what truth there might be in them. The effects could not be denied, but they were capricious; and in view of Prof. Elihu Thomson's discovery, it seems possible that the luminosity may have been visible to sensitive percipients when there was a trace of magnetic dust in the room and when other light was not excluded. The obvious precaution of excluding other light may have been the condition which militated against the examination of the phenomenon, which it was then thought was presumably of a subjective character.

Helicopters.

ONE often sees published statements to the effect that a helicopter has been invented and that wonderful things are expected of it. If the design gets as far as an actual trial a few alterations are found to be required, and then nothing more is heard of the matter.

To make a machine which without an extravagant expenditure of power will raise itself vertically and remain poised in the air is possible and most desirable, and the many failures in the attempt to do this are all attributable (omitting mistakes in mechanical design) to the same cause, namely, that of giving an insufficient area to the lifting surface.

The sort of area required may be gathered from the following illustration. Let two aeroplanes facing in opposite directions be connected by a few hundred yards of light line joining their wing-tips. The machines so connected could rise and circle round each other without much difficulty. When in the air the line might be hauled in until the wing-tips were almost in contact, and in this condition the combined machines would form a helicopter. There would be no banking, as the connecting line would take the centrifugal force, but more power would be required than when the machines were flying independently on account of the lower speed and efficiency of the inner pair of wings.

The function of a screw or lifting surface is to generate a downward current of air, the reaction of which on the surface shall be equal to the weight supported. If L^2 is the cross-section area of this current (dependent on, though not identical with, the area of the lifting surface), V its velocity, and W the weight, $L^2V^2\times$(constant somewhat greater than half the density of air)$=$W. Hence LV is a constant, and V is inversely proportional to L.

The power required to maintain the current is WV, and can therefore be reduced by making L/V large.

For instance, if W can be sustained on a current of area L^2 by P horse-power, only half this power would be required if the current area were $4L^2$.

A. MALLOCK.

A Physical Interpretation of the Energy Quantum.

THE work of Bohr (*Phil. Mag.*, 1913–15) indicates that we may assume stability only for *some* electronic orbits, *i.e.* amplitude changes occur discontinuously. We arrive at a similar conclusion in the case of the vibrating atoms of solids if we accept the quantum explanation of the change in their specific heats with temperature.

It is here suggested that the amplitude of a periodic disturbance in the æther can alter only by definite amounts which depend on its frequency, so that as soon as any part of a wave-front meets with something that is capable of inducing a decrease in amplitude, such as a suitably situated electron, that part suffers a definite decrease of amplitude, which extends back into the wave-train (uniformly in all directions in an isotropic medium) to the extent of one quantum. The æther is relieved of its energy of strain, not continuously, but in quanta.

With the modification suggested above the wave theory renders understandable, on one hand, phenomena such as interference, and, on the other, phenomena such as the photo-electric effect, a detailed discussion of which is here impossible owing to lack of space.

More light might be thrown on this subject by a mathematical treatment.

University Statistics of the United Kingdom, 1919–20.[1]

UP to the year 1913–14 the Board of Education presented Annual Reports relating to university institutions in England and Wales in receipt of grants from the Board, but during the war this publication was discontinued. The volume now issued by the University Grants Committee marks the end of this five-years statistical holiday and the starting-point of a series of returns which, including, as they do, Scottish and Irish institutions in receipt of annual grants, and, as they presumably will, the Universities of Oxford and Cambridge and Trinity College, Dublin, will be far more comprehensive and significant than the pre-war returns published by the Board of Education. In eight comparative tables the public is provided with an abundant, but compact, store of information regarding university students of both sexes—whence they came, at what ages they were admitted, where they resided while pursuing their studies, the directions and durations of the courses they followed, the degrees and diplomas they gained—as well as complete statements of the grants made from the Treasury in each of the years 1913–14 to 1919–20. These are followed by notes and statistics and accounts concerning each institution separately. The notes are arranged under such heads as "Faculties and Subjects," "Extension Work," "Cost of Living and Hostel Facilities," "Local Support." To the accounts of income and expenditure are appended expenditure schedules showing, separately for each department, the salaries of departmental heads, number and salaries of other teachers, cost of departmental and laboratory maintenance, etc. In future years income and expenditure are to be tabulated in comparative statements, and the cost per student of each institution is to be exhibited.

In the following paragraphs an attempt is made to indicate the more salient features of the information given in the collated statistics, and as these do not, as yet, include the students of Oxford, Cambridge, Trinity College, Dublin, the colleges at Durham, Guy's Hospital Medical School and some other schools of the University of London, and University College, Exeter, supplementary figures have been quoted from the 1921 edition of "The Yearbook of the Universities of the British Empire."

The *number of full-time students*, as given in the tables, was 37,081, of whom 27 per cent. were women. The total for England alone, 20,486, may be analysed topographically as follows, using round numbers: London institutions, 8000; North Midland group of universities—Birmingham, Leeds, Liverpool, Manchester, and Sheffield—with the Manchester College of Technology and Nottingham University College, 9300; Bristol University, with the Merchant Venturers' Technical College and the University Colleges of Southampton and Reading, 2000; Armstrong College and the College of Medicine, Newcastle-upon-Tyne, 1200. The totals for Wales, Scotland, and Ireland are 2473, 10,992, and 3130 respectively. Compared with the returns for 1913–14, the numbers show increases of 83, 101, 31, and 76 per cent. in England, Wales, Scotland, and Ireland.

The results obtained by adding to the above figures statistics from the "Yearbook" may be stated thus: Oxford and Cambridge (including 1100 women), 11,800; London, 10,100; North Midlands, 9300; the rest of England, 3400; Scotland and Wales, as above; Ireland, 4500; grand total of full-time students, 52,600.

In any estimate of the significance of these statistics it is important to bear in mind that a very large number of persons engaged in studies of university grade are not accounted for either in the Grants Committee's tables—because they are not students of grant-receiving institutions—or in the "Universities' Yearbook"—because they do not belong to any university or university college. The institutions in the United Kingdom in which professional education of university grade is provided, although they are not organically connected with any university—theological colleges, training colleges, agricultural colleges, schools of mines, etc.—are numerous and important. Moreover, there are many students reading privately for the external degrees of the University of London, for the Bar, etc. On the other hand, it must be remembered, as pointed out in the Grants Committee's introduction to its returns, that there were in 1919–20 nearly 17,000 full-time ex-Service students in attendance at university institutions in the United Kingdom (including 11,500 attending institutions in receipt of Treasury grants), and that when this special source of supply comes to an end there may be a substantial fall in the numbers.

Again, in any attempt to compare the number of university students in the United Kingdom with the corresponding number in, for example, the United States of America, where, in 1918, there were 224,000 men and 151,000 women in 672 universities, colleges, and professional schools, it would be necessary to allow for several important differences in the conditions of higher education between the countries compared. For example, the work of the higher forms of many of our secondary schools corresponds with the earlier stages of the work done in many of the American colleges and collegiate departments of universities, and in many of the American institutions the enrolment of part-time students constitutes a very large proportion of the total number. In France the number of students in 1913–14 in the University of Paris (17,500) and the fifteen provincial universities amounted to 39,000, but special branches of knowledge, tech-

[1] Returns from Universities and University Colleges in Receipt of Treasury Grant, 1919–20. Presented to Parliament by the University Grants Committee, April, 1921. (Cmd. 1263.) 3s. 6d.

nology, and research were cultivated in numerous institutes and schools outside the universities.

A new and interesting feature of the returns is the classification of full-time students according to *locality of home residence*. The homes of approximately 60 per cent. were within 30 miles of the university, of 35 per cent. in other parts of the United Kingdom, of 4 per cent. (1390) within the British Empire overseas, of 2 per cent. (646) in foreign countries. The following institutions drew a noticeably high percentage of their students from beyond the 30-mile radius: University of Glasgow (50 per cent.), London Medical Schools (52), King's College Household and Social Science Department (58), Westfield College (61), University Colleges of Galway (62), Dublin (71), Reading (72), Aberystwyth (78). Those most frequented by students from outside the United Kingdom are shown in the following list, wherein the first figure (A) represents the total number of such students, and the second (B) the number from *foreign countries*:

	A	B
University of Edinburgh	494	58
,, ,, Glasgow	202	100
,, ,, Aberdeen	52	7
,, ,, Birmingham	139	48
,, ,, Liverpool	56	9
Armstrong College	49	41
Royal Technical College, Glasgow ...	41	24
College of Technology, Manchester ...	51	29
Imperial College of Science and Technology	90	42
London Medical Schools	338	60
London School of Economics ...	88	75
University and King's Colleges, London	176	54

It will be noticed that a large proportion of the students from overseas in schools of technology and the London School of Economics were foreigners.

As regards Oxford and Cambridge and the other university institutions which find no place in these tables, the "Yearbook" does not indicate the sources from which their students are supplied, but the Universities Bureau of the British Empire a few months ago collected lists of students from other countries, both British and foreign, studying in the universities and university colleges of the United Kingdom, and it has permitted the publication of the following totals, taken from these lists, of students from (*a*) the British Empire overseas, (*b*) foreign countries: Oxford (*a*) 307, (*b*) 308; Cambridge (*a*) 290, (*b*) 126; Dublin (*a*) 91, (*b*) 2; Guy's Hospital Medical School (*a*) 195, (*b*) 26. The Oxford figures reflect the influence of the Rhodes Scholarships, which provide for the continuous residence at Oxford of 186 scholars drawn from the United States of America (two from each State), as well as from Canada and Newfoundland, Australasia, South Africa, the West Indies, and Malta. Apart from this, however, Oxford exerts on American students a powerful attraction, as is shown by an analysis of the (*b*) figures given above. Separating students from the United States of America (*c*) from other foreign students (*d*), the totals for Oxford are (*c*) 217, (*d*) 91; for Cambridge, (*c*) 34, (*d*) 92. Nearly all the students from overseas at Trinity College, Dublin, came from South Africa.

From the same source the following statistics have been compiled: Students from Asia, 1228; Africa, 1046; Europe, 703; America and the West Indies, 676; the Pacific (Australasia), 282. The countries contributing most largely to these totals are listed below with the distribution of the students to London (*a*), Oxford and Cambridge (*b*), Edinburgh (*c*), and Glasgow (*d*):—

	Total	(*a*)	(*b*)	(*c*)	(*d*)
India, Burma, and Ceylon	974	418	200	157	58
South Africa	781	267	155	178	30
U.S.A.	362	72	251	25	4
Australia and New Zealand	279	50	151	57	4
Egypt	223	78	13	28	4
Canada and Newfoundland ...	164	33	105	18	1
China	112	36	14	22	10
Japan	54	34	7	2	3
Russia	113	70	25	4	5
Serbs, Croats, and Slovenes	75	7	18	11	9
Rumania	68	32	3	2	4
France	66	21	15	2	3
Norway	62	20	8	3	12
Greece	50	17	18	1	3

Of the students from South Africa, 229 were at the London Medical Schools, and 32 at Aberdeen. Of those from Egypt, 51 were at the London Medical Schools, 41 at Manchester and Liverpool, and 39 (24 medical) at Birmingham.

In future years the Grants Committee will present a comparative statement showing the number of new entrants who had previously attended a secondary school for three years or more, and the number who commenced their education in a public elementary school. In a few cases this information is given for 1919–20 in the separate chapters devoted to the several institutions; thus the College of Technology, Manchester, reports that of 286 full-time students 137 began their education in a public elementary school.

"The increasing demand for *Halls of Residence* and for more facilities for corporate life," says the Committee in its introduction, "makes it important to show the extent to which provision of the kind is made." Accordingly, Table 1 classifies students with reference to university residence. Half of them, it appears, lived at home, 37 per cent. in lodgings (22 per cent. of the women and 42 per cent. of the men), and 11 per cent. (4025) in halls of residence, these

constituting 26 per cent. of the women and only 5 per cent. of the men. These proportions would, of course, be very different if the figures included the students of Oxford, Cambridge, and Trinity College, Dublin. In Wales, Scotland, and Ireland the proportion of students in lodgings is much higher—of those living at home, lower—than in England. There are good grounds for believing that future returns will show a substantial increase in the proportion of students living in halls of residence. Meanwhile, it may be noted that accommodation of this kind has already been provided for 80 per cent. of its students by Reading University College, for 47 per cent. of their students by the London Women's Colleges, for 36 per cent. by Dublin University College, for 30 per cent. by the University Colleges of Southampton, Aberystwyth, and Bangor, and for 23 per cent. by the University of Bristol.

The total number of full-time students admitted in 1919–20 for the first time for degree and diploma courses is given in Table 2 as 17,381, of whom rather more than one-fifth were women. They represent half and 38 per cent. respectively of the full-time men and women students in the institutions in question. The *ages at admission* of two-thirds of the men and one-half of the women were nineteen and over; of four-fifths of the men and five-sixths of the women, eighteen and over; while only 352 men and 53 women were under seventeen. Of these last-mentioned juvenile entrants Glasgow is responsible for 71, Birmingham for 51, and East London College for 26.

Table 3 gives particulars of *part-time students* taking courses of university standard. The total number, 15,234, of whom 23 per cent. were women, includes (*a*) 10,524 occasional, (*b*) 2389 diploma, (*c*) 890 degree, (*d*) 576 research, and (*e*) 1055 other post-graduate students. The chief contributors to these totals were :—

	(*a*)	(*b*)	(*c*), (*d*), (*e*)
Royal Technical College, Glasgow	2787	255	—
London School of Economics	1934	28	228
University and King's Colleges, London ...	1493	391	796
University of Leeds ...	661	33	39
University of Sheffield ...	416	663	34

Tutorial classes are organised in co-operation with the Workers' Educational Association by all the universities of England and by those of Wales, Aberdeen, Edinburgh, and Belfast. Particulars given in the several returns show that upwards of 5000 students attended these classes.

Research students were at work in all the institutions figuring in the returns except a few medical schools. Their total number was 1009, including 533 full-time students. Women researchers numbered 339. London institutions had 586 research students, Manchester 133, Liverpool 126, Birmingham 43. Post-graduate students other than those engaged in research numbered 1592, including 1055 part-time students. London alone accounts for 869 of these (765 part-time). Such data as are available for estimating the number of research and other post-graduate students at work in the university institutions excluded from these tables point to a total of about 1200.

The classification of full-time students *by faculties* gives the first place to medicine, including dentistry, with 12,657, including 2949 women. In the faculties of arts, theology, law, music, commerce, economics, and education were 11,745, including 5309 women; in pure science, 6571 (1538 women); in engineering, applied chemistry, etc., 6114 (145 women). Medical and dental students were most numerous in London (3347), Glasgow (1838), Edinburgh (1739), Liverpool (741), and Aberdeen (704). They outnumbered all other students put together in Belfast and the colleges of the National University of Ireland (in University College, Dublin, they were in a majority of almost 2 to 1), and were above 40 per cent. of the total in Glasgow, Aberdeen, and Edinburgh. Corresponding figures for Oxford, Cambridge, and Trinity College, Dublin, are not available. The statistics of degrees and diplomas gained so soon after the war present, of course, abnormal features. The total numbers of recipients were: Of degrees, 4054, including 1275 women; diplomas, 2062 (599 women); degrees according to faculties: arts, theology, law, music, commerce, economics, and education, 1666; pure science, 1074; medicine, 1008; engineering, applied chemistry, etc., 306.

Tables 7 and 8 exhibit the Treasury grants, annual and special, made to university institutions for 1913–14, when they amounted to 442,147*l.*, and each later year to 1919–20. The annual grants show but few important variations up to 1918–19, but in the following year they were increased, on the whole, by 70 per cent., and amounted to 786,500*l.* Of this, 198,000*l.* went to London institutions, 260,000*l.* to others in England, 52,500*l.* to Wales, 165,000*l.* to Scotland, and 111,000*l.* to Ireland. The special grants amounted to 104,000*l.* in 1915–16, 12,000*l.* in 1918–19, and 304,000*l.* in 1919–20, in which year special emergency grants pending the reports of the Royal Commissions inquiring into their financial resources were received by Oxford (30,000*l.*), Cambridge (30,000*l.*), and Trinity College, Dublin (12,000*l.*). The Civil Service Estimates of March last show 1,000,000*l.* for grants in 1920–21, and 1,500,000*l.* for grants in 1921–22. A further sum of 500,000*l.* is provided for grants in 1921–22 to the Federated Superannuation Funds for Universities. The principles upon which it is proposed to allocate grants in future are discussed in a report presented by the University Grants Committee on February 3, 1921, a paper which is likely to exercise a far-reaching influence on the further development of our universities and their relations with the State.

Protective Measures against X-rays and Radium.

A COMMITTEE was recently formed in London to see whether some general precautionary measures could be outlined which would be of service to those employed in the use of X-rays or radium for medical, scientific, or industrial purposes. The members of the committee are as follows: Sir Humphry Rolleston (chairman), Sir Archibald Reid, Dr. Robert Knox, Dr. G. Harrison Orton, Dr. S. Gilbert Scott, Dr. J. C. Mottram, Dr. G. W. C. Kaye, and Mr. Cuthbert Andrews. Dr. Stanley Melville and Prof. S. Russ are acting as honorary secretaries to the committee. The need for a statement on this subject has been felt for some time. During the war the Röntgen Society issued a printed card pointing out the dangers of exposing parts of the body to X-rays unduly, but the uses of these forms of radiation are becoming so numerous in medicine and the arts that it was felt that the ground should be gone over in more detail, and general recommendations drawn up as to the conditions under which work of this character should be carried out.

The preliminary report of the committee has just been issued. It is a carefully thought-out statement of present knowledge in regard to the equipment, ventilation, and working conditions of X-ray and radium departments. We are glad to see from the introduction to the report that the committee holds the view that the dangers which may attend the use of these radiations can be avoided entirely by the provision of efficient protection and suitable working conditions.

The damage which people have suffered in the past falls into two categories:—

(1) Visible injuries to the superficial tissues which may result in permanent damage.

(2) Derangements of internal organs and changes in the blood. These are especially important, as their early manifestation is often unrecognised.

The protective measures to be employed naturally vary with the work in hand, and the report contains details of the measures which the committee thinks appropriate to (1) X-rays for diagnostic purposes, (2) X-rays for superficial therapy, (3) X-rays for deep therapy, (4) X-rays for industrial and research purposes, (5) electrical precautions in X-ray departments, (6) ventilation of X-ray departments, and (7) radium therapy.

The report concludes with a statement bearing upon several aspects of the subject, and we accordingly reproduce it in full:

"The governing bodies of many institutions where radiological work is carried on may wish to have further guarantees of the general safety of the conditions under which their *personnel* work.

"(1) Although the committee believe that an adequate degree of safety would result if the recommendations now put forward were acted upon, they would point out that this is entirely dependent upon the loyal co-operation of the *personnel* in following the precautionary measures outlined for their benefit.

"(2) The committee would also point out that the National Physical Laboratory, Teddington, is prepared to carry out exact measurements upon X-ray protective materials, and to arrange for periodic inspection of existing installations on the lines of the present recommendations.

"(3) Further, in view of the varying susceptibilities of workers to radiation, the committee recommend that wherever possible periodic tests—*e.g.* every three months—be made upon the blood of the *personnel*, so that any changes which occur may be recognised at an early stage. In the present state of our knowledge it is difficult to decide when small variations from the normal blood-count become significant."

It is satisfactory to learn that the committee intends to continue to meet and to consider the advisability of directing some researches which arise out of the considerations involved in the memorandum in question.

Suggestions and offers of personal or other assistance are invited; they should be forwarded to the honorary secretaries of the X-ray and Radium Protection Committee, from whom copies of the preliminary report may be obtained, c/o Royal Society of Medicine, Wimpole Street, W.1.

Cosmogony and Stellar Evolution.[1]

By J. H. Jeans, Sec.R.S.

I.—*The Evolution of Gaseous Masses.*

THE progress of observational astronomy has made it abundantly clear that astronomical formations fall into well-defined classes; they are almost "manufactured articles" in the sense in which Clerk Maxwell applied the phrase to atoms. Just as atoms of hydrogen or calcium are believed to be of similar structure no matter where they are found, so star-clusters, spiral nebulæ, binary stars are seen to be similar, although in a less degree, no matter in what part of the sky they appear. The problem of cosmogony is to investigate the origins of these comparatively uniform formations and the process of transition from one class to another.

In attacking this problem the cosmogonist of to-day stands upon the shoulders not only of previous cosmogonists, but also, what is of even greater importance, upon the shoulders of the brilliant and industrious astronomical observers of the past century. We shall find it convenient

[1] Lectures delivered at King's College on May 3 and 10.

to take as our starting point the most famous theory of cosmogony ever propounded—the nebular hypothesis of Laplace—and we shall examine to what extent it remains tenable in the light of modern observational and theoretical research.

Laplace's hypothesis referred primarily to the genesis of the solar system, which he believed to have originated out of a hot nebulous mass that shrank as it cooled. The nebula was supposed to be in rotation, so that the principle of conservation of angular momentum required that as the mass cooled its speed of rotation should increase. It is well known that a mass either of gas or of liquid in rotation cannot rest in equilibrium in the spherical shape which would be assumed in the absence of rotation. If the rotation is very slow the equilibrium shape will be an oblate spheroid of small eccentricity. As the rotation increases, the ellipticity will increase, but it is found that the spheroidal shape is soon departed from. Laplace believed, as a matter of conjecture rather than of reasoned proof, that with continually increasing rotation a mass of gas would in time reach a stage at which it could no longer exist as a single continuous mass. When this stage was reached he believed that a ring of particles would be discharged from the equator through the centrifugal force of rotation outweighing the centripetal force of gravitation. The mathematical researches of Roche (1873) provided some support for this general conjecture, and more recent investigations put its general accuracy beyond doubt.

It is found that the changes of shape which accompany increase of rotation are, in their general features, the same for all masses, whether gaseous or fluid, provided only that there is sufficient central condensation of mass. When the rotation becomes so great that the spheroidal figure is departed from, the equator of the mass is found to pull out into a pronounced edge which ultimately becomes perfectly sharp (see Fig. 1). The mass has now assumed a lenticular shape, and any further increase of rotation results in matter being discharged from this sharp edge. The lenticular shape is retained from now on, the sharp edge acting like a safety valve and emitting just so much matter as is necessary to carry off the excess of angular momentum beyond the maximum which can be carried by the central mass.. Fig. 1 shows the configurations of the lenticular figures for masses of gas in adiabatic equilibrium, in which γ (ratio of specific heats) has the extreme values 1·2 and 2·2 respectively. Other calculated lenticular figures show generally similar shapes. With a further increase of rotation beyond that for which these curves are drawn, the figures would remain unaltered save for the addition of a distribution of matter in the equatorial plane—the matter already thrown off from the sharp edge of the lens.

If gaseous stars assume these forms our telescopes refuse to reveal them. Even in the most powerful telescopes the stars remain infinitesimal points of light; the only bodies which show any observable shape are the nebulæ. It is highly significant that a number of these exhibit precisely the lenticular shape just described. This is in most cases accompanied by a distribution of matter in the plane through the sharp edge of the lens. A number of such nebulæ have been found by direct spectroscopic observation to be in rotation about an axis perpendicular to this plane. Thus there is very strong justification for supposing that these nebulæ are masses of gas or other matter with high central condensation behaving precisely as imagined by Laplace—rotating and throwing off their excess of angular momentum as they cool by the ejection of matter in their equatorial planes.

There is, however, almost incontrovertible evidence that the nebulæ which have just been described are nothing but ordinary spiral nebulæ seen edgewise, for observation discloses a continuous sequence of nebulæ the shapes of which bridge completely the gap between the lenticular nebulæ, in which we are looking at right angles to the axis of rotation, and the familiar spiral nebula in which we look approximately along this axis. The characteristic nebula shows a nucleus which we can now identify with the lenticular

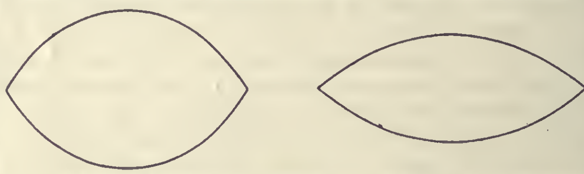

FIG. 1.—Figures of equilibrium for rotating masses of gas.

figure demanded by theory, having two arms emerging symmetrically from opposite points of the nucleus. If our identification is correct these arms must be formed out of the matter already discharged from the nucleus. It has in point of fact been found by van Maanen and Kostinsky that the matter in the arms appears to be in motion approximately along the arms and in the outward direction.

Any external gravitational field, whether of the universe as a whole or of neighbouring stars or nebulæ, would produce a tidal field similar to that produced by the sun and moon on the surface of our earth, a field specified mathematically by a second harmonic. This field, no matter how small in amount, would suffice to destroy the exact circular shape of the "equator" of the nucleus and so would concentrate the emission of matter at two opposite points on this equator. Thus it is easy to understand why the nebulæ, as a rule, exhibit two symmetrical arms emerging from antipodal points. It is very much less easy to understand why these arms should be of the universal spiral form—the absence of any explanation of this form must be regarded as a serious drawback to our interpretation of the spiral nebulæ. It is readily proved that the ejected filaments of matter, whatever the shape they assume, could not remain of uniform line-density.

Such a distribution of density would be unstable, and it can be proved that nuclei would form at approximately equal distances, around which the matter of the arms would condense. In this way it is possible to explain the nuclei and condensations which are observed in the arms of the spiral nebulæ. It is also found possible to calculate the amount of matter which will condense around each nucleus; the mass of each is found to be of the order of magnitude of the known masses of the stars.

In this way I have been led to conjecture that the spiral nebulæ are whirling masses of gas which, owing to their rapidity of rotation, throw off gaseous stars much as a "Catherine-wheel" firework throws off sparks. If so, the condensations in the arms of these nebulæ are stars in the process of birth. Dynamically the mechanism is almost identical with that imagined by Laplace as resulting in the birth of systems of planets and satellites, but on a far more stupendous scale. The final product of the chain of events we have been considering must be some type of star-cluster—perhaps a globular star-cluster, or possibly an "island-universe" similar to our galactic system. The difficulties in the way of an exact mathematical investigation into the history of the ejected gas as the filaments condense around nuclei and as these form stars and begin to move as detached bodies are enormous. On the other hand, the determination of the final steady states possible for a system of stars created in this way is quite simple. There is found to be only one type of final steady state possible for a system of stars created out of a rotating mass of gas, and this shows exactly the features presented by the system of stars of which our sun is a member. The system of stars will be of a flattened shape, symmetrical about the plane of greatest cross-section (the galactic plane in our system); the velocities in any small region of space will not be distributed at random, but will show a preference for two opposite directions ("star-streaming"); these directions will be parallel to the plane of symmetry and perpendicular to the radius to the centre of the system. This last direction is that given by Charlier for the direction of "star-streaming" in our system. Our system passes all tests for having been born out of a spiral nebula the plane of which was what is now the plane of the Milky Way; indeed, Easton and others have claimed to find traces of the two spiral arms still surviving in the distribution of stars in this plane, as though the final steady state had not yet been reached.

Let us now turn to a study of the lives of individual stars. To the naked eye the stars appear as mere points of light of varying brightness. The telescope adds little except possibly differences of colour. The spectroscope appears at first to add a wealth of new information, but a detailed study of stellar spectra discloses the unexpected fact that all stellar spectra, apart from a few exceptions, fall into one single linear series. Photographs of the spectra of all stars, in which varying exposures have been made to compensate for varying brightnesses, can be arranged uniquely in a consecutive order in which each spectrum differs only imperceptibly from its neighbour. All the complicated diversities of stellar spectra appear to be determined, in the main, by one single variable. This is believed, with good reason, to be the temperature of the star's surface.

Positions on this linear series are specified by reference to six selected points denoted by the letters B, A, F, G, K, M in this order. The order given is that of decreasing surface temperature. Stars having B-spectra are of bluish colour with a surface temperature of 10,000° C. or more. Stars of type M are red with a surface temperature of only 3000° C. Our sun is of type G, with a surface temperature of about 6000° C.

We might also arrange the stars in order of brightness. The distances of many stars are known, and for these we can calculate the "absolute brightness" or "luminosity"—*i.e.* the amount of light emitted as compared with our sun. Since the masses of the stars are all approximately the same, it might be expected that the order of "luminosity" would prove to be substantially the same as that of surface temperature, but this does not prove to be the case. Eight years ago it was found by Hertzsprung and H. N. Russell that the red M-stars fell into two widely different classes, one class having abnormally high luminosity, and the other abnormally low. The ratio of luminosities in the two classes is of the order of 10,000 to 1, and since the surface temperatures are the same, this ratio must imply a corresponding ratio in the areas of the radiating surfaces. Thus the two classes of M-stars must have volumes in a ratio of about 1,000,000 to one, for which sufficient reason they have been designated "giants" and "dwarfs." From a comprehensive discussion by Russell, recently confirmed by Adams and Joy, it is clear that the demarcation between "giants" and "dwarfs" extends, although with diminished intensity, through the types K, G, and F, while at types A and B the classes coalesce.

Lately Shapley, by determining the distances of the globular clusters, has greatly increased our knowledge of stellar luminosities, and has calculated the individual luminosities of 1152 giant stars in clusters. If we plot the logarithms of the luminosity (or the absolute magnitude) against spectral type as in Fig. 2, the vast majority of Shapley's 1152 stars are found to lie within the belt marked "giants," while of the stars previously discussed by Russell and by Adams and Joy nearly all lie either within this belt or within that marked "dwarfs." In this diagram a few typical stars have been marked. The stars α Orionis and our near neighbour Lalande 21.185 are examples of giant and dwarf red stars. The diameter of the former has recently been found by direct measurement to be about 300 times that of our sun, corresponding to a density of the order of at most one-thousandth of that of atmospheric air; the latter has a luminosity only 0.009 times that of the sun, and probably a mean density com-

parable with that of the earth. Our sun and our nearest stellar neighbour, α Centauri, are marked as typical dwarfs of type G, and Sirius is a representative A-type star.

From the known luminosity and surface temperature of any star it is easy to calculate its surface and so its density. Giants of types G and K are found to have densities of the order of 0·004 and 0·0005 respectively, agreeing with the known densities of binary stars of these types. Sirius, with a luminosity of forty-eight times, and a surface temperature about one and a half times, those of our sun, must have a surface nine times as great. Its mass is 3·4 times the solar mass, so that its density must be about 0·2. In general it is found that all giant stars must be gaseous, of

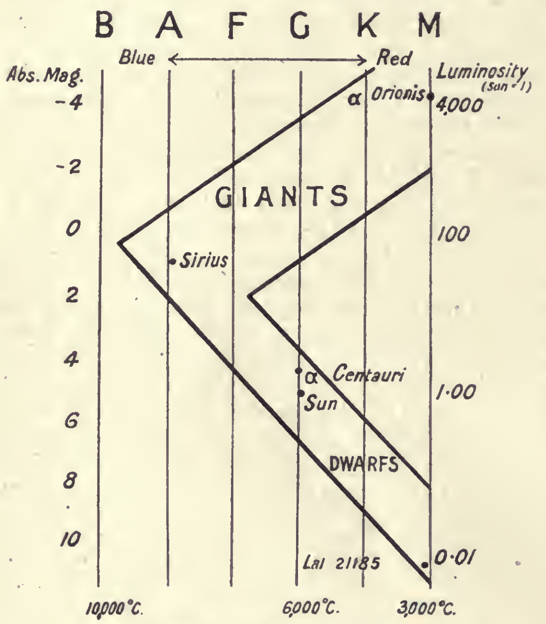

FIG. 2.—Luminosity-temperature diagram.

density so low that the ordinary gas-laws will be approximately obeyed. Dwarf stars may be gaseous or liquid or solid, but, if gaseous, they are so dense that the gas-laws will be nowhere near the truth. It is now easy to see why, in the giant stars, increase of temperature and density go together; this is merely a consequence of Lane's law. But the dwarfs may be thought of as approximating rather to masses of fixed dimensions, and for these the luminosity falls off as the temperature decreases.

Our sun radiates light at a rate of about 2 ergs per second per gram of its mass. Gravitational contraction, as Lord Kelvin showed, could provide energy at this rate for only about 20,000,000 years, and radio-active and chemical energy could only slightly lengthen this period. For a giant star, radiating at 1000 times the rate of the sun, the maximum period would be only a few thousand years. This period is far too short, and it is now generally accepted that, so far from gravitation and known sources of energy providing the whole of a star's radiation, they can provide only an insignificant fraction. Energy of adequate amount can originate only from sub-atomic sources, as, for instance, from internal rearrangements in the positive nuclei of the atoms or from the transformation of a small fraction of the star's mass into energy. It is a matter of simple calculation to show that all other stores of energy in a star can constitute only an insignificant reservoir of energy which, unless continually replenished from sub-atomic sources, would be exhausted in, astronomically, a moment. Thus the rates of radiation and of generation of sub-atomic energy must be practically equal, and the luminosity of a star will be determined by the latter rate at any instant.

We may now think of the evolution of the stars as represented by the march of a vast army through our diagram (Fig. 2), the individuals keeping, for the most part, within the marked belt. Each individual takes his marching orders from the supply of sub-atomic energy, and so long as we remain in ignorance of the exact source and nature of this we cannot be certain whether the motion of the army is up or down, or even that it is all in the same direction. But if we are right in conjecturing that the stars were born out of a nebula of very low density, the order of march will be from low density to high; our army will be marching downwards in the diagram. Its tail, except for a few stragglers, is about at absolute magnitude -4, its head is lost in darkness. In the next lecture we must study the incidents which may occur during the march of this army of stars.

(To be continued.)

Obituary.

DR. A. M. KELLAS.

BY the death of Dr. A. M. Kellas we have lost one of the best authorities on the effect of high altitudes on the human system. No one else had so great a practical knowledge, or worked scientifically at the subject with more persistence than he.

Born in Aberdeen, he was educated there, and afterwards went to Edinburgh, London, and Heidelberg. For some time he was assistant to Sir William Ramsay, and afterwards lecturer on chemistry at Middlesex Hospital.

As a teacher he was most successful, taking endless trouble in helping backward students. In pure chemistry he did little research, his chief contribution being a long and careful investigation on "The Determination of the Molecular Complexity of Liquid Sulphur," published in 1918. But during the last ten years he gave up most of his spare time to study the physiological and physical

difficulties connected with the ascents of high mountains.

This subject he was particularly fitted to investigate, for he had probably climbed to heights above 20,000 ft. more often than anyone else. For instance, in 1910, in the Sikkim Himalaya, he was nine times above 20,000 ft., the highest altitudes being the first and only ascents of Pawhunri, 23,180 ft., and Chumiomo, 22,430 ft.

He also visited other parts of the Himalaya, the Nanga Parbat district, north of Kashmir, and Garwhal, where last summer he reached 23,600 ft. on Kamet. It was, however, in Sikkim that he did most of his mountaineering.

From time to time he published papers and reports in the Journal of the Royal Geographical Society and in the *Alpine Club Journal*. But as he was of a retiring disposition, there are few accounts of his extraordinary mountaineering record. Perhaps his most important paper was on "A Consideration of the Possibility of Ascending the Loftier Himalaya" (Journal of the Royal Geographical Society, 1917), in which he discussed all the factors conditioning acclimatisation to high altitudes, and the question whether it was possible to climb Mount Everest. His conclusion was: "A man in first-rate training, acclimatised to maximum altitude, could make the ascent of Mount Everest, without adventitious aids (*i.e.* oxygen), provided that the physical difficulties above 25,000 ft. are not prohibitive."

Dr. Kellas had a unique knowledge of the Sikkim Himalaya, and his death has deprived the Mount Everest expedition of one of its most valuable members, for he had studied the geography of the country round Mount Everest more deeply than anyone else.

WE regret to report the death, on June 26, of MR. WILLIAM SHACKLETON, at the age of fifty. Mr. Shackleton received his early training at the Keighley Institute, and after completing a three years' course at the Royal College of Science, became an assistant to the late Sir Norman Lockyer. By his skill and enthusiasm he contributed largely to the success of the early work at South Kensington on the photography of stellar spectra. In 1893, in company with Mr. Albert Taylor, he observed the total eclipse of the sun in Brazil, and was one of the first to obtain photographs with a prismatic camera of adequate power. In 1896, with Dr. E. J. Stone, he took part in the expedition which was conveyed to Novaya Zemlya by Sir George Baden-Powell in his yacht *Otaria*. Favoured by a brief interruption in a snowstorm, he then achieved a notable success in photographing for the first time the complete "flash" spectrum, with perfect definition, notwithstanding that an accident to the yacht had left but little time for preparation. On this occasion some admirable photographs of the corona were also obtained under his supervision. This expedition was further memorable for a meeting with Nansen at Hammerfest on his return from the polar regions.

For some years Mr. Shackleton was occupied with the late Dr. Common in the design of range-finders and other optical instruments, and a special interest in optics was added to that in astronomy during the remainder of his life. In 1905 he took up an appointment at the India Stores Depôt as Inspector of Scientific Supplies, and scientific workers in India have profited much from his extensive technical knowledge and careful supervision of their requirements. Mr. Shackleton was elected a fellow of the Royal Astronomical Society in 1893, and of the Optical Society in 1913. He was secretary of the Optical Society from 1916 to 1920, and rendered valuable services to the society in that capacity, besides contributing papers of practical importance; he was a vice-president of the society at the time of his death. Mr. Shackleton's health had not been good for several years, but his death came unexpectedly, and will cause deep regret to his many friends in scientific and technical circles.

Notes.

A CHEMICAL laboratory of a new type was opened at the Imperial College of Science and Technology by Mr. A. J. Balfour on June 24. The laboratory is fitted with apparatus of a size which will render it necessary for chemical processes to be carried out under conditions closely resembling those which are present on the large scale. Just as the ordinary scientific laboratory contains specimens of all types of apparatus necessary for small-scale work, the new laboratory contains appliances which will enable the student to carry through the corresponding large-scale operations in a manner which will render it possible for him to study the influence of those factors, such as heat exchange, etc., which are not of vital importance in ordinary laboratory work. Students, and especially research students, whether they intend to follow an academic or an industrial career, will thus obtain a knowledge of large-scale conditions which it has hitherto been possible to acquire only by actual works experience. Moreover, the means for preparing initial material in large quantities will be of the greatest value for the research workers in the chemistry department of the college. It is hoped that a full description of the new laboratory, with illustrations, will appear in a forthcoming number. The equipment was provided by Mr. W. G. Whiffen, an old student of the college.

WE learn from the *Times* of June 24 that the West London Hospital is in possession of electrical plant capable of delivering current at 200,000 volts for X-ray purposes. The X-rays are of a penetrating character, and are being used for the treatment of patients suffering from malignant disease, on the lines laid down by the Bavarian doctors Seitz and Wintz. The

use of more and more penetrating X-rays in medical work has been a gradual growth, and, quite apart from any marked differential action which the short wave-length radiation may have on cancer cells as compared with the longer wave-lengths, the employment of the more penetrating rays has technical advantages when dealing with deep-seated tumours. One sees in their use a natural development which depends very largely upon the electro-technician. It is greatly to be deplored that statements as to how this development may improve the results of cancer treatment are based, not upon facts, but upon the hopes of those engaged in this work. The use of X-rays and of radium in the treatment of cancer has been justified by results, and these results continue to improve, but we think that the public may be expecting more than is warranted when it is told that "a conservative estimate of the possibilities of the new treatment is to put the number of cures in the future at double that ever known in the past."

On June 27 the president of the Royal Society of Arts, the Duke of Connaught, presented the Albert medal of the society to Dr. J. A. Fleming "in recognition of his many valuable contributions to electrical science and its applications, and specially of his original invention of the thermionic valve, now so largely employed in wireless telegraphy and for other purposes." It may be of interest to recall the important part that Dr. Fleming played in the development of the thermionic valve and its applications to wireless telegraphy and telephony. The first form of valve was made in 1904, and led to revolutionary developments in that and other branches of electrotechnics. It is perhaps less generally realised that he gave scientific assistance in the early developments of "wireless" so far back as 1899, and directed some of the constructional work in connection with the first long-distance station at Poldhu. Dr. Fleming was also actively connected with the early progress of electric lighting in this country. In 1882, and for twelve years after, he held an advisory position with the Edison Electric Light Co., of London, and later with the Edison and Swan Co. He carried out the installation on board one of the first ships of the Royal Navy to adopt the new illuminant when it was introduced in 1882, and during succeeding years assisted several of the London companies and provincial corporations in electric lighting matters. Still older is his connection with telephony, for so far back as 1879 he was scientific adviser to the Edison Telephone Co., formed to begin telephone-exchange working in London. Other scientific work which Dr. Fleming has accomplished includes an important research into the electric and magnetic properties of matter at very low temperatures carried out in conjunction with Sir James Dewar.

On June 22 a portrait of Sir Napier Shaw, painted by W. W. Russell, was presented to him by the staff of the Meteorological Office, South Kensington, for preservation in the office. A copy of the portrait was presented to Lady Shaw.

An International Hydrographic Bureau has been established at Monaco, with the following directors: Vice-Admiral Sir John Parry (Great Britain), Capt. Phaff (Netherlands), and Capt. Muller (Norway). The secretary is Capt. Spicer-Simson (Great Britain).

It is announced in the *British Medical Journal* for June 25 that the International Labour Office has decided to appoint a committee of experts to deal with the question of industrial hygiene. Accordingly letters have been dispatched to the Governments of Great Britain, France, Belgium, Germany, Holland, Italy, Spain, Sweden, Switzerland, and Japan, inviting each of them to nominate one of its health inspectors or factory inspectors as a member of the advisory committee. The committee will meet from time to time, preferably on the occasion of the International Labour Conference, and its members will keep in touch with the International Labour Office and its industrial hygiene section by correspondence.

The twelfth annual meeting of the Oxford Ophthalmological Congress will be held on July 7–9, when the following communications will be made:—Discussion on "The Causes of Infection after Extraction of Senile Cataract," Dr. V. Morax and others; "Stereoskopometry," R. J. E. Hanson; Petrosal sinus sepsis, A. Greene; The Doyne memorial lecture on "Heterophoria," E. E. Maddox; An instrument which is set in motion by the eye, *i.e.* by vision, or by proximity of the human body, *e.g.* the hands, Dr. C. Russ; Experiences of 606 and its substitutes in eye diseases, J. Hern; The trench operation for chronic glaucoma, with account of cases, N. C. Ridley; A plea for early diagnosis and operation in chronic glaucoma, with some remarks upon the treatment of acute glaucoma, Dr. T. H. Butler; A modified operation for chronic glaucoma, P. H. Adams; Some points in the performance of the Lagrange operation for chronic glaucoma, B. Cridland; Loss of vitreous during cataract extraction, Dr. T. H. Butler; Sight-testing with coloured test types, P. J. Hay; Some points of interest in the work of a school oculist, Dr. H. McIlroy.

An exhibition, free of charge, of Egyptian antiquities from Tell-el-Amarna will be held in the rooms of the Society of Antiquaries on July 5–13, from 10 a.m. to 5 p.m. A lecture on "The Season's Work at Tell-el-Amarna" will be delivered by Prof. T. E. Peet on July 7, at 8.30, in the Royal Society's rooms.

The seventy-third annual meeting of the Somersetshire Archæological and Natural History Society will be held at Crewkerne on July 19–21, under the presidency of Sir C. Hercules Read, who will deliver his presidential address, "Somerset Archæology—a Suggestion," at 11.20 a.m. on the opening day.

The first exhibition of prehistoric art, organised by the Society of Friends of Art under the superintendence of the well-known archæologist, Don Elias Tormo, is now being held at Madrid. The object of the exhibition is to display reproductions of the remarkable series of rock paintings from the Spanish caves, the first discovery being that of the Altamira cave-paintings by the small daughter of the archæologist Sautuola in 1879. Since that date discoveries,

encouraged by the Prince of Monaco and others, have been made in great numbers. The present exhibition includes what are supposed to be examples of early Iberian script, figures of suns, fishes, horseshoes, women weaving short skirts, drawings of the chase, tiny and most artistic stags from the eastern regions of the Peninsula, and splendid life-size wild boars and bisons from Altamira in the north-west. These figures, in drawing and colouring, are splendid examples of prehistoric art.

BARON EDMOND DE ROTHSCHILD has intimated to the Paris Academy of Sciences his intention to place at the disposal of the Academy the sum of 10,000,000 francs for the purpose of creating a fund for the development of physico-chemical research in France. According to the *Morning Post*, the revenue from the capital sum will be used first for assisting young students who devote themselves to pure science; secondly, to furnish investigators with the means to carry out their work; thirdly, to help inventors who have made discoveries as a result of being assisted by the new foundation to take out patents protecting their discoveries; and, fourthly, to create later on, if it should be deemed necessary, an institute with laboratories to be named after the founder.

AT the annual general meeting of the Röntgen Society, held on June 16, the following officers and council were elected:—*President:* Prof. J. W. Nicholson. *Vice-Presidents:* Dr. G. H. Rodman, Sir Ernest Rutherford, and Sir William Bragg. *Hon. Treasurer:* Mr. G. Pearce. *Hon. Secretaries:* Dr. E. A. Owen and Dr. J. R. Reynolds. *Hon. Editor:* Dr. G. W. C. Kaye. *Council:* C. Andrews, Dr. H. Black, A. E. Dean, Major Kenelm Edgcumbe, N. S. Finzi, Dr. F. L. Hopwood, Dr. F. H. Johnson, Dr. R. Morton, C. E. S. Phillips, Prof. A. W. Porter, Prof. A. O. Rankine, and Sir Archibald D. Reid.

THE seventy-fourth annual meeting of the Palæontographical Society was held in the rooms of the Geological Society, Burlington House, on Friday, June 17, Mr. E. T. Newton, vice-president, in the chair. The report referred to the completion of Dr. Reed's monograph of Bellerophontacea, and the early publication of a new monograph of carboniferous insects by Mr. Herbert Bolton. It also announced further instalments of the monographs of Pliocene Mollusca, Palæozoic Asterozoa, and Pleistocene Mammalia (Hippopotamus). The size of the annual volume had unfortunately to be reduced owing to the higher cost of production and to the difficulty of increasing the membership of the society. Dr. J. S. Flett, Mrs. Longstaff, Mr. A. W. Oke, and Dr. C. T. Trechmann were elected new members of council. Dr. Henry Woodward was re-elected president, Prof. E. J. Garwood was elected new vice-president, and Mr. Robert S. Herries and Dr. A. Smith Woodward were re-elected treasurer and secretary respectively.

THE council of the Society of Chemical Industry has nominated Prof. R. F. Ruttan, of Montreal, as president for the session 1921–22. The council, in view of the fact that the current annual meeting will be held in Montreal, requested the Canadian sections to suggest one of their members for nomination for the office of president, and Prof. Ruttan's name was proposed.

EARLY last year, as announced in NATURE, the Medical Research Council, by the courtesy of the Governing Body of the Lister Institute, made arrangements to maintain a national collection of type cultures at the institute. The scheme is under the general direction of Prof. J. C. G. Ledingham, with Dr. R. St. John Brooks and Miss M. Rhodes as curator and assistant curator respectively. It now appears that mycologists feel the need of a similar collection. Since the formation of such a collection is not at present contemplated by any institution it is considered that the scope of the national collection should be extended. The British Mycological Society has appointed a fully representative standing committee to consider the ways in which the collection can be made most valuable, and to advise and assist in all questions appertaining to fungi. It is proposed to collect and maintain cultures of fungi of importance in phytopathology, medicine, veterinary science, technology and soil biology, types useful for teaching purposes, and any rare or interesting species. At present it is not possible to cope with the innumerable strains of common fungi, and room can be found only for those forms with some published distinguishing name or symbol. The co-operation of bacteriologists and mycologists is earnestly invited, and in return every effort will be made to supply the needs of applicants for cultures. All communications respecting the collection should be addressed to the Curator, National Collection of Type Cultures, Lister Institute, Chelsea Gardens, S.W.1.

THERE was an interesting demonstration of new wireless telegraph apparatus by the R. M. Radio Co. on Thursday last. This company has developed and shown in operation a Morse printing wireless receiver, which, in addition to the ordinary detector and amplifier valves, is provided with another valve, to rectify the currents that would normally go into the receiving telephone circuit, so that a relay can be made to work. The relay is of a sensitive Post Office pattern, and is actuated by upsetting the balance of a Wheatstone bridge arrangement, in one arm of which the valve is connected. The relay controls an ordinary Morse inker, so that a permanent record of the messages is produced. This apparatus is due to Mr. F. H. Haynes, of the R. M. Radio Co., and Mr. V. Ramage, of the Central News, Ltd., and can easily take down messages from Paris, Moscow, etc., as well as from ship installations up to a considerable distance. Capt. H. de A. Donnisthorpe also showed a new form of thermionic valve known as the R.M.R. triode. In this, improved efficiency is obtained by the use of a hemispherical anode which avoids the fringing effect produced by the more usual cylindrical electrodes, and thus utilises the electron stream more completely. In a further development of this apparatus a "soft" tube of this kind is surrounded by a current-carrying coil, which produces a magnetic field having the effect of concentrating

the ions where they are wanted, so that an increased flow of electrons is produced, giving a steeper characteristic curve and improving the sensibility by something like a further 50 per cent. The increased anode current when the field was applied was seen by means of an ammeter, and in another experiment the effect of a powerful electromagnet in controlling the position of the glow in a softer tube was demonstrated. It was pointed out that this action is similar to that taking place in the aurora borealis, according to the theory that in the layers of reduced pressure of the upper atmosphere the earth's field concentrates the ions and thus locates the glow produced by the bombardment of electrons shot off from sun-spots. This apparatus, which Capt. Donnisthorpe calls the "Thermagnion," can also be used to produce continuous oscillations with an equal gain in efficiency.

THE tercentenary of the death of Thomas Harriot, the mathematician and astronomer, occurs on July 2. Not only was he the most celebrated English algebraist of his time, but he was also one of the first astronomers in England to use a telescope, and, like Galileo, Fabricius, and Scheiner, was one of the early observers of the spots on the sun. Born at Oxford in 1560, he was a year older than Henry Briggs. He graduated from St. Mary's Hall, and became an ardent student of mathematics forty years before the inauguration of the first university chair of mathematics. At the age of twenty-five he entered the service of Sir Walter Ralegh, by whom he was employed in the survey of the newly founded colony of Virginia. The greater part of Harriot's life, however, was passed in the neighbourhood of London, where he came under the patronage of Henry Percy, Earl of Northumberland, who gave him a pension and assigned him rooms at Sion House, which stands on the banks of the Thames opposite Kew. When the earl was confined to the Tower through the complicity of some of his family in the Gunpowder Plot, Harriot and two other mathematical worthies, Thomas Hughes and Walter Warner, often bore him company. They were known as "the three magi." Harriot appears to have passed an uneventful life, and at his death was buried in St. Christopher's Church, on the site of which now stands the Bank of England. A monument erected to his memory was destroyed in the Great Fire of 1666. As an algebraist Harriot is a connecting link between Vieta and Descartes. His "Artis Analyticæ Praxis" was not published until ten years after his death. The revival of his fame as an astronomer was due to von Zach, who, while on a visit to the Earl of Egremont in 1784, discovered some of Harriot's writings beneath a pile of old stable accounts at Petworth Castle; while the reduction of Harriot's observations of the comet of 1607 formed one of the first tasks of Bessel's astronomical career. Some of Harriot's manuscripts are in the British Museum.

AT the annual meeting of the British Pharmaceutical Conference at Scarborough on June 14, Mr. E. Saville Peck, in his presidential address on "British Pharmacy and its Possibilities," said he looked forward to the time when pharmacy in this country shall have established itself as a separate professional entity. It could not be raised to this status without the combined efforts of its members, and would have to move forward with the advance of general education and of applied science. In his opinion every student before registration should be required to pass one of the school leaving certificate examinations which the Board of Education has recognised as equivalent to matriculation. While not advocating any serious extension of the syllabus for the qualifying examination, Mr. Peck favoured the addition of commercial science. In the major examination, which should be renamed the fellowship examination, practical physiological chemistry and bacteriology (with clinical microscopy) should be included among the compulsory subjects, and steps should be taken to establish a degree in science with pharmaceutics as one of the subjects in the final examination. If pharmacy is to take its position with other professional bodies it must bring its final qualification up to university standard. He looked forward to the ultimate evolution of a real profession of pharmacy.

MRS. SCORESBY ROUTLEDGE has made another important contribution to our knowledge of the ethnology of Easter Island in her account of a series of carved rocks and stone houses, published in the Journal of the Royal Anthropological Institute (vol. l., part ii.). The houses built of slabs of stone procured from an adjoining quarry are remarkable. The soil is excavated on a sloping site; the foundations are made of large rough cubes of rock, on which slabs are laid on edge, and the roof is formed of similar slabs. The house is entered by a rectangular tunnel. A series of excellent photographs enables us to understand the methods of construction, and the accommodation provided for the occupants.

IN *Ancient Egypt*, 1921, part ii., Prof. Flinders Petrie explains that the work of the British School has been moving southward, in the course of a systematic clearing of the western bank of the Nile valley. The excavation of the cemetery of Herakleopolis, which had been wrecked in ancient times, provided some important results. In particular, a number of well-dated skeletons gave an opportunity to compare them with those of other sites on either side—Medum, Tarkhan, and Deshashe. This showed important differences between the types of the Second, Sixth, and Ninth Dynasties, but the question whether the interments were those of nobles or of plebeians may to some extent confuse the results.

IN the April issue of the *Entomologist's Monthly Magazine* Dr. R. C. L. Perkins writes on the variation exhibited by the British species of parasitic bumble-bees of the genus Psithyrus. It is evident from the many colour forms which are recorded in this article that variation in these bees has been very inadequately studied. The subject is an interesting one, and species of Psithyrus need to be much more extensively collected before we shall be able to learn the distribution of their varietal forms. Dr. Perkins also refers to the very rare bumble-bee *Bombus pomorum*, Panz. A few examples of this insect were

captured by the late F. Smith in Devon in 1857, but since that time the species has been lost sight of in this country. Owing to the resemblance which the male bears to a variety of the same sex in *Psithyrus rupestris*, F., and the similarity of the female to more common Bombi, Dr. Perkins is of opinion that *Bombus pomorum* may have been overlooked, and possibly may be re-discovered by some enterprising entomologist.

PAMPHLET No. 12 (1921) of the Economic Series issued by the British Museum (Natural History) is written by Mr. F. Laing, and deals with the ubiquitous cockroach. In addition to the common species (*Blatta orientalis*, L.), three other kinds of cockroach have established themselves in sufficient numbers in this country to be occasionally troublesome. The general reader is far more interested in their control than in their biology, and Mr. Laing finds that a powder consisting of three parts of sodium fluoride to one part of pyrethrum is a successful remedy. The mixture should be scattered about the haunts of the cockroaches in the evening, and the dead ones removed the next morning. The powder is harmless to any domestic pets and is cheaply and easily prepared.

THE inhabitants of Buckinghamshire and Hertfordshire will be grateful to Mr. W. Whitaker for his memoir on the water-supply of the two counties, recently published by the Geological Survey. In both counties chalk is the principal water-bearing rock, but supplies are also obtained from overlying gravels, sands, etc., Tertiary beds, and the Greensand and Jurassic rocks. The deepest bores recorded are 1000 ft., and from some of the wells more than 1,000,000 gallons a day are being obtained. Numerous analyses of the water are given, and the details are of considerable interest to all concerned in the well-being of the community. The geological student will be particularly interested in the full description of the swallow holes in which surface-water disappears, and which are numerous in Herts. Probably the best known are those in North Mymms, which can easily be seen at Water End; here the drainage of some 20 square miles of the county is lost. Swallow holes are found in two sets of conditions: along the junction of the Tertiary beds and chalk, and in the chalk itself, where the saturation level is below the bottom of the valley. The former are active at all seasons, the latter may not be. Directions are given for finding good examples. There is also an interesting discussion on the effect of pumping on the adjacent wells.

A PAPER by Mr. S. H. Warren on "A Natural 'Eolith' Factory beneath the Thanet Sand" (Quart. Journ. Geol. Soc., London, vol. lxxvi., p. 238, 1921), has already raised considerable discussion. It is clear that many persons would have accepted Mr. Warren's naturally flaked specimens as eoliths had their early Eocene age and their mode of origin not been demonstrable. The specialists in eoliths, on the other hand, maintain that the natural product, due to interaction under earth-tremors, is inartistic compared with an eolith for which human origin can reasonably be claimed. Mr. Warren's "natural factory" occurs at Grays in Essex.

IN a short paper of four pages, reprinted from the Proceedings of the U.S. National Academy of Sciences for June, 1920, Prof. A. G. Webster, of Clark University, directs attention to a necessary connection between the equation of state of a gas and the specific heats of the gas at constant pressure and at constant volume which does not take the simple form given to it by some authorities. In particular, he shows that a characteristic equation of the form $T=pf(v)$ does not indicate that the two specific heats are independent of the pressure; on the contrary, neither of them is a constant or independent of the pressure, nor is their difference constant, although it is independent of the pressure. Such a gas has no cohesion pressure, although it may have a finite Joule-Kelvin effect. In the same way a gas having a characteristic equation of the form $T=vF(p)$, although it has a zero Joule-Kelvin effect, has specific heats which are neither constant nor independent of the pressure. In conclusion, Prof. Webster expresses the opinion that the present method of teaching thermodynamics by means of the equations of the ideal gas or of the van der Waals equation "is by no means conducive to clearness."

WE have received from the Decimal Association a pamphlet entitled "The High-Value Penny," in which a proposal is put forward to increase the token value of the penny and employ the existing penny, half-penny, and farthing coins to represent values 20 per cent. higher than at present, thus dividing the shilling into ten pence instead of twelve, while leaving the values of the shilling and the £ sterling unaffected. All the existing notes and silver coins would be retained at their present values, and the sixpenny and threepenny coins employed as half-shilling and quarter-shilling pieces exchangeable into 5 and $2\frac{1}{2}$ high-value pence instead of 6 and 3 low-value pence respectively. At convenience the unpopular silver threepenny piece could be withdrawn from circulation and a more useful nickel twopenny piece issued. It is claimed that by the adoption of this proposal the purchasing power of the penny would be brought into closer harmony with modern needs. Owing to the absence of a coin intermediate in value between 1*d*. and $1\frac{1}{2}$*d*., the price of articles sold at 1*d*. before the war has been increased earlier than necessary to $1\frac{1}{2}$*d*., and will be retained longer than necessary at this figure when prices are falling. The chief defects of the recent decimal coinage proposals would be avoided by continuing to reckon in pence instead of in mils, and no new coins or knowledge of decimal arithmetic would be required.

IN the *Meteorological Magazine* for May Dr. C. Chree gives a brief account of "Recent Work on Aurora." The subject was suggested to him by the installation of an observatory in Shetland, one of its objects being auroral observations. Due acknowledgment is made of the work done by Norwegian physicists. Arcs and curtains are said to be the most frequent forms of aurora portrayed, and many, if

not all, are built up of rays. Illustrations are given both from drawings and from a photograph, the preference being given somewhat to the former method, although reference is made to the method devised by Prof. Störmer of measuring auroral heights by taking photographs simultaneously from the two ends of a base, the inclusion of stars determining the position of the aurora in space. Reference is made to the exceptional occurrence of aurora in England, whilst it is said that in high latitudes aurora seems to be the rule, rather than the exception, when the sky is free from cloud and the absence of strong moonlight permits. It is suggested that the spectrum of aurora at different heights may add to our knowledge of the composition of the atmosphere and throw light on the electrical conditions of the air, whilst relations to wireless phenomena are also foreshadowed. The occurrence of aurora, associated with the sun-spots in May, although apparently of little importance in England, may in more northern latitudes afford useful information.

WE understand that part 1 of vol. iv. of "Annual Tables of Constants and Numerical Data: Chemical, Physical, and Technological," is now ready. The work since 1910 has been published under the patronage of the International Union of Pure and Applied Chemistry. Copies are obtainable from M. Ch. Marie, 9 rue de Bagneux, Paris 6e.

MR. W. H. ROBINSON, 4 Nelson Street, Newcastle-upon-Tyne, has just circulated a lengthy catalogue (No. 3, 1921) of upwards of 1000 second-hand books. The contents are of a varied character, but many items should be of interest to readers of NATURE, *e.g.* a number of books illustrated by Thomas and John Bewick, folk-lore publications, and those in the large section devoted to science and technology. The prices asked appear very moderate.

Our Astronomical Column.

OCCULTATION OF VENUS.—A daylight occultation of Venus will take place on Saturday morning, July 2 (civil reckoning). The planet's stellar magnitude will be $-3\cdot9$, and it should be plainly visible to the naked eye, especially with the lunar crescent as a guide. The following table is extracted from the B.A.A. Journ. for May, p. 302:—

Place	Summer time of Disap. h. m.	Summer time of Reap. h. m.	Angle from N Pt. °	Angle from N Pt. °	Altitude °	Altitude °
Greenwich ...	5 3·4	6 9·5	67	262	23	33
Edinburgh ...	5 11·8	6 14·2	58	273	22	31
Liverpool ...	5 6·6	6 10·4	62	268	22	31
Dublin ...	5 6·3	6 8·2	59	271	20	29

The times are for the centre of Venus; they should be diminished by about 0·5m., owing to the error of the moon's place. Venus will be just half-illuminated. The occultation (disappearance and reappearance) of the illuminated limb will take place about 28s. later than the centre. Accurately timed observations of the different phases will be of use for correcting the places of moon and planet.

Circular No. 10 of the Cracow Observatory gives full details of the circumstances for about 400 stations spread over Europe. These circulars are written in Prof. G. Peano's "Latino sine flexione," which is easily read by anyone with an elementary knowledge of Latin or the derived languages.

THE TOTAL AMOUNT OF STARLIGHT.—Prof. Newcomb pointed out the importance of ascertaining the total amount of light given to us by all the stars, including those that are altogether invisible as units in the largest telescopes. It is only in this manner that limits can be fixed to the amount of light given by the fainter and more distant stars. Prof. Newcomb himself made observations for this purpose (*Astrophys. Journ.*, vol. xiv.); he was followed by Mr. G. J. Burns (*Astrophys. Journ.*, vol. xvi.), Mr. L. Yntema (Groningen Publications, No. 22), and Dr. P. J. Van Rhijn. The last-named has now made a new and more complete research (Groningen Publications, No. 31), utilising the experience previously gained, and analysing the total skylight into its components. An artificial star of magnitude about 5 was used, formed by reflection from a bulb; its light was compared with that of standard stars, and then spread out by changing the focus until it became equal to the skylight. The observations were made at Mount Wilson; the nearest towns were distant 13 km. and 26 km., and the effect of their lights was found to be inappreciable above altitude 35°. Use was made of the star counts in different galactic latitudes to estimate the increase of starlight as the galaxy is approached. The final result is that the total starlight is equal to 1440 first magnitude stars (Yntema found 1350), and that the skylight is made up as follows:—Starlight, 17 per cent.; zodiacal light, 43 per cent. (this varies at different hours of the night); perpetual aurora, 15 per cent. (it is noted that Prof. Slipher found the green auroral line on all photographs of the sky spectrum); the preceding sources scattered by the atmosphere, 25 per cent. The starlight has been reduced to the zenith by the application of Abbot's coefficients of atmospheric absorption. The starlight per square degree in various galactic latitudes is:—Lat. 0°, 0·085; lat. 10°, 0·065; lat. 20°, 0·044; lat. 30°, 0·026; lat. 40°, 0·015; lat. 50°, 0·014; lat. 60°, 0·012; lat. 70°, 0·011; lat. 80°, 0·010; and lat. 90°, 0·010 (the unit is mag. 1·0).

PERIODICITY OF VARIABLE STARS.—In order to facilitate further research on the cause of the periodicity of variable stars, Dr. J. G. Hagen has collected together in the May number of *Scientia* the salient differences between the stars of period less than three months and those of greater period. The short-period stars change less than 1·5 magnitude, while those of long period change three or four magnitudes. For the former the minima are sharp, followed by a rapid recovery, while for the latter the minima are flattened and the recovery relatively slower. The long periods oscillate, while the short change in the same direction with time. The former collect about 300 days, the latter about half a day and five days. The long-period stars are generally orange-red in colour and are spread evenly over the sky, while the short-period stars are whitish-yellow and collect in the Milky Way.

Dr. Hagen looks forward to the appearance of the results of the Mount Wilson measurements with the new 100-in. telescope, and hopes that it will then be possible to test whether the phenomena can all be explained by the theory that the variable stars are binaries.

Royal Sanitary Institute: Folkestone Congress, June 20–25.

THE Royal Sanitary Institute was founded in 1876. For more than forty years it has been, as it were, a chorus to interpret to the official and general public the methods of applying scientific ideas to the improvement of the environment and to the promotion of individual health. Among its earliest congress presidents it included Edwin Chadwick, Ward Richardson, Douglas Galton, and others well known in the history of the modern public health movement. The annual congress has always been a convenient occasion either for the announcement of some fresh application of hygienic ideas or for the discussion of administrative difficulties in their realisation. This year the congress was held at Folkestone. The Earl of Radnor was president. In his address he pleaded for the retention of the voluntary hospital system, arguing that unpaid medical service is somehow superior to paid service. There is, perhaps, a sense in which the consultants of the great and small hospitals are unpaid, but it is an abuse of words to suggest that they are philanthropists. The hospital problem, however, is rapidly coming to a point when discussion will yield to action, and with their usual elastic adaptivity our institutions will emerge into something better. The "science" of the transition will not be traceable until after the event. His lordship's plea was put with lucidity and dignity—a typically good illustration of a voluntary administrator's attitude. The later discussion on hospital service and medical service generally took a much wider sweep, and made manifest how far we have already travelled along the lines of official medical organisation. But this is a practical rather than a scientific question, and may safely be left to the administrators.

Not so the question of smoke prevention. Doubtless it is a practical question, and is probably as old as the oldest British health congress. It is one of the by-products of the industrial revolution. From the merely commercial point of view the waste has been incredible, whether we think of the factories or of the home fires; but not until the last twenty or thirty years have the evil effects of smoke-spoiled light and air begun to be understood or studied scientifically. More than twenty years ago, at Glasgow, Sir William Ramsay in a popular lecture put forward the suggestion that the fog-clouds due to smoke absorbed the sun's violet and ultra-violet rays, and, therefore, prevented those rays from having their proper germicidal effect on the bacterial life of the streets; hence the increase of microbic epidemics. The remedy, he said, was to use gas-fires. Sir William Ramsay at a later stage bettered this when he suggested the production of energy from coal without bringing it to the surface. These suggestions deserve exploiting. But Prof. Leonard Hill, of the Medical Research Council's Department, put the whole problem in a new setting. This is what we should expect from a man whose experimental work has given a richer meaning to the term "ventilation," and shown that our cardinal practical concern should be with the cooling-rate of the body in relation to the air. On the present occasion he explained the peculiar effects of light, particularly the visible rays. "Men live long who work in the clean moving air and sunshine of the fields. While the expectation of life for females (1911–12) in Westmorland was 66·6 and in the rural districts of Norfolk and Suffolk 61·03, it was in the county boroughs of the North 49·93, in Middlesbrough 46·65." It need not be assumed that the whole responsibility for this rests on smoke, but the cumulative case against it is very strong. On the other hand, the positive value of light in its effects on metabolism is extraordinarily high. This is accepted in therapeutics. "The visible (luminous) rays of sunlight are of immense importance, because they penetrate the skin and locally warm up the blood, which absorbs them in the subcutaneous vessels, while the body as a whole is kept cool by the cool moving air." (This refers to the sun-treatment of tubercular bones and joints in Alpine sanatoria.) "On the other hand, the dark heat rays are absorbed by the surface of the skin and make this warm. The ultra-violet rays have also no power to penetrate. They are absorbed by as little as one-tenth of a millimetre of the outer horny layer of the skin." It is, then, the luminous, not the ultra-violet, rays that have "so powerful an effect on health." The inference from this double fact is obvious. "Sunlight warming the blood locally, cold moving air keeping the body cool and stimulating metabolism, open-air exercise—these are the great factors for health next to good food and sufficient sleep, and of these the people of the cities are largely deprived." There are many practical deductions, but it will take the medical schools and the administrative authorities a long time to exhaust the value of this piece of science revealed by research.

In supplement to Prof. Hill's paper, Dr. Owens, of the Committee on Atmospheric Pollution, gave actual figures as to the tons of matter per square mile deposited from the air. The broad facts are (*a*) that industrial smoke is a small fraction of the whole and can be completely controlled by existing methods, and (*b*) that domestic smoke accounts for a vastly greater quantity, and at present cannot be controlled. That is the smoke problem.

There were many other practical discussions, each involving a good deal of nascent science. For example, the discussion of infant feeding is, in spite of the innumerable army of skilled observers, still losing itself among unresolved factors. Dr. Vynne Borland showed that in certain cases the overfeeding of infants results in wasting. This conclusion was based on carefully analysed cases. Dr. Jervis gave other cases to show that in certain forms of malnutrition no variation of food has any effect, and that here we are face to face with unknown factors, such as deficiency or excess of secretion in the endocrinal glands. It seems clear that until the relatively rough work of clinical treatment can be better illuminated by the work of the laboratories we shall have to continue our practice empirically.

Science is taking a steady grip of industrial fatigue. Mr. Wilson, of the Industrial Fatigue Research Board, gave a summary of results under the title "Some Effects of Environment on Efficiency and Safety." Temperature, humidity, ventilation, and lighting, all have definite relations to output, but the precise effects are not easy to estimate. Heavy work in high temperatures produces more in winter than in summer. Good ventilation is found to neutralise the reducing effects of humidity. In silk weaving artificial light reduces production by 10 per cent. compared with daylight. There is an obvious case for continuing research into these "raw materials" of industry, if only to secure some scientific basis for a system of "welfare work."

The science of rat destruction was represented at the congress. Research has not got much beyond the "aniseed" of the older rat-catchers and certain familiar poisons. Mr. Claremont, of the Ministry of Agriculture, gave a careful summary of facts. The rat, it appears, is "peculiarly susceptible [to

poisons], for it has a very delicate stomach, and, I believe, cannot vomit; at any rate, does not readily do so." There is room for an extended biological and psychological study of the rat, for it does seriously affect the commerce of the world both directly as a consumer and indirectly as the international carrier of plague.

Perhaps the most fascinating item of the congress programme was the popular lecture by Prof. Mellanby, of Sheffield, on "Vitamins." A health congress without a discussion on diet would be a solecism, and to-day the whole theory of diet has been transfigured by the "vitamin" hypothesis. It is well to regard the word as provisional, for in this way the methods of research are likely to remain more fluid. No one has established a better right than Prof. Mellanby to be heard on the recent developments. He set forth the data with persuasive lucidity. He showed that experiment discredited the old view that diet could be exhaustively expressed in terms of proteins, carbohydrates, fats, salts, and water. There is a *sextum quid*. From Eyckman's discovery that beri-beri was due to rice robbed of certain portions by "polishing" to the latest experiments with puppies to show the production and arrest of rickets, Prof. Mellanby made clear the reasons for assuming the existence of the three factors: Fat-soluble A, water-soluble B, and the anti-scorbutic factor. The work of Prof. Mellanby and his wife in this field is well known to the technical and official public, but there is much need to spread the ascertained facts among the wider public, for this is the only way to generate sufficient pressure to secure that the consumer shall have the benefit of the latest discoveries. The fact that hypotheses are disputed is no reason for not making them known. In this matter the facts even as now ascertained are of high practical value. The physiological and biochemical departments of the various schools ought to work in more intimate touch with the administrative public, especially with the clinical investigators.

Of the congress as a whole it can be said truly that the mayor and councillors did everything to show that they understood the importance of the institute's educational work, and as we parted in the clean air and light of a perfect summer day we assured each other that on the scientific, as well as on the social, side it had been "a very nice congress."

The Importance of Research in the Development of the Mineral Industries.[1]

By SIR RICHARD REDMAYNE, K.C.B.

THE present state of the civilised world is, economically, paradoxical. The need for commodities is very great, yet the production of them is so costly that industry is languishing for lack of orders. On the termination of the war, after four years of excessive waste and destruction, the world is found short of houses, food, and other commodities; railways and rolling stock are in sad need of repair, restoration, and expansion; the output of fuel, the life-blood of our economic existence, is greatly decreased, and the mines from which it is produced are in a backward state of development.

The cessation of hostilities was succeeded almost at once by a period of feverish industrial activity—it would be erroneous to apply the words "general prosperity"—followed by a cycle of great depression. The demand for goods is great, but production is falling. What is the explanation? It lies, I think, in a combination of circumstances:—

(1) A feeling of insecurity due to unsettled political and financial conditions. Hence a disposition to conserve rather than to utilise in commercial ventures such capital as is available.

(2) The incidence of rate of exchange.

(3) The high cost of production consequent on the high cost of living and the higher standard of comfort demanded (and rightly demanded) by the labouring classes than formerly obtained.

(4) The lower, and still apparently decreasing, productive power of labour.

The first two conditions will in part right themselves in process of time as the various political problems are solved, or partly solved, and rates of exchange will then tend towards the normal; but a very great deal depends upon the last two conditions, as the future position of production is not easy to forecast. Higher and cheaper production is a difficult desideratum to obtain in view of the high rate of wages now ruling and the diminishment in working time either achieved or claimed by the manual workers of the day, and these are demands which are not likely to show much abatement in the future. What is the solution? The answer I venture to give, the solution which I presume to propound, to this problem, is "research." To discover by research cheaper means of production, and by research to create new outlets.

The object, then, of my address to-day is to direct attention to the necessity for research work in the mineral industries. Let me make more clear what I have in mind by taking one special case in point, a most important case—that of coal. It is an axiom that a cheap and plentiful supply of suitable fuel is necessary for our prosperity as a manufacturing country. This situation will remain, and is bound to remain, until some other means of producing power cheaply is discovered.

I think it may be taken that, roughly speaking, the rate per cent. of return on the capital invested in coal-mining in Great Britain over the last hundred and fifty years has, on the average, not varied much—reckoning in, say, periods of ten years—yet the progress made during the last two or three generations in every respect, except in the rate of return on capital, has been enormous.

Thus such everyday features of a colliery working at the present time as shaft cages and guides, the safety lamp, the steam locomotive, the trade in coke and by-products, ventilating fans, wire ropes, mechanical haulage, mechanical screening, the use of compressed air, the application of electricity to signalling, lighting, and motive power, and the mechanical cutting of coal have all been introduced in the course of the last hundred and twenty years. There is scarcely an appliance (save the simplest tools) or a machine in use at a modern colliery which could have been made at the beginning of the nineteenth century; and during this period the wages of the workmen—I omit the war period and the present abnormal time from consideration—have been increased certainly between 200 and 300 per cent., and this though the price of coal did not greatly increase; as a matter of fact, between the years 1828–1900 the variation was small and the price was lower in the latter year than in the former.

It was *because* of the improvements introduced into coal-mining that it was possible to keep down the

[1] Address delivered at the annual meeting of the British Science Guild held at the Goldsmiths' Hall on June 8.

cost of production, allowing of an increasing trade being done and the maintenance of a fair return on the capital invested in the industry. Further improvements are, to my mind, the only satisfactory solution to our present economic difficulties. Let me repeat: Lessen the cost of production by applying new methods, the result of research, and by research discover extended and new uses for minerals. Let me briefly indicate examples of possible research work in the mineral industry.

Coal—mineral fuel—naturally occurs at once to the mind. I am one of those who believe that the cost of production can be reduced by the wider application of the most up-to-date methods of the "getting" of the coal, in the transport and usage of the coal, but I doubt very much, even if and when these methods are applied to the fullest extent practicable, whether it will be possible to reduce the price to quite the pre-war level.

In some of our largest industries coal, next to wages, is the highest item of cost. The way of research would, therefore, appear to lie along the lines of the more efficient *use* of coal.

We know in the smelting of Cleveland iron in Yorkshire under present methods that about 74 per cent. of the total available heat of the fuel used is usefully applied, which for economy of smelting large quantities of iron is a remarkable result to have achieved. But is it beyond the bounds of possibility to reduce the consumption of one ton of coke to produce one ton of iron? And, as was pointed out by the Coal Conservation Committee in their final report of 1918, the economy of fuel which would result from the combination in single units of coke-ovens, blast furnaces, steel furnaces, and rolling mills would be very great indeed. The idea was foreshadowed in Belgium and Germany in the early years of the present century, and in 1910 Mr. T. C. Hutchinson, in his presidential address to the Cleveland Institution of Engineers, expressed the view "that the time would shortly come when ironstone would be brought in at one end of the works and finished steel would be turned out at the other, only such coal being used as was required for the coke-ovens to make sufficient coke to smelt the ironstone." In 1913 Mr. Hutchinson repeated this belief at the Brussels meeting of the Iron and Steel Institute, and in 1912, in his presidential address to the Iron and Steel Institute, Mr. Arthur Cooper also expressed the belief that the time was close at hand when the iron and steel industries would be forced by the stress of competition to adopt this reform.

The economic utilisation of low-grade fuels is a matter of great moment. There are in the United Kingdom, as in all coal-producing countries, vast quantities of coal which it does not pay to work owing to the low price realisable thereon. Probably the use of so-called colloidal fuel offers a solution, and will render the use of these low-grade coals practicable and profitable; for very fine coal mixed in about equal quantities with fuel oil produces a fuel which can be burnt in the same way as oil, and, bulk for bulk, though not weight for weight, gives in thermal values results equivalent to those of the fuel oil alone.

The recovery of coal and its more perfect cleaning by the froth flotation process, for some years applied to the recovery of metalliferous ores from their associated gangue, presents features of interest and probable profitable results.

The low-temperature carbonisation of coal, too, is at present occupying the minds of many investigators and may lead to the more extensive use of low-grade fuels. But to be commercially successful such a process should be continuous, and the resultant fuel capable of being sold at a price below that of coal.

Oil Shale.—The stores of liquid mineral oil will not last for ever; indeed, it is probable that the next fifty years will see, if not the exhaustion of this source of oil, a great reduction in the supplies available. We must turn, therefore, towards distillation of oil-bearing mineral—oil shales and coal—to take the place of our present petroleum supplies. Although there are very few retorts erected in the United States for the treatment of oil shale, and such as are are being applied to experimental purposes only, yet even that country of oil supplies is turning its attention to the consideration of its oil-shale potentialities. Research work would naturally be directed towards the economic desulphurisation of the oil and the minimising of losses in refining, so allowing of oil shales being worked which at present cannot be made available. The loss in refining oil from Scotch oil shale is about 23 per cent. of the crude oil treated, as compared with a loss of $3\frac{1}{2}$–4 per cent. only in the case of straight-run refining of American petroleum. The process of refining is the process of getting rid of offensive substances, but in those cases where refinement results in such high losses, as in the case of shale oil, it is probable that other than the objectionable substances are lost—substances which might be retained with advantage in the finished product.

Iron.—I have already alluded to the cheaper reduction of iron ores. The available reserves of high-grade iron ores in Great Britain are vastly nearer exhaustion than are the coal supplies. More and more, too, the world will have to turn to the poorer grade of ore—a wide field is here offered for research work in devising economic methods for their reduction. The economic smelting of ferruginous sands, in which connection may be mentioned those of Sweden and New Zealand, has so far defeated the efforts of metallurgists, rich in iron though these sands are.

In connection with blast furnaces, two products, the possible recovery of which is worth investigation, are those contained in the dust in the gases, namely, iron and potash; these dusts contain a high percentage of iron.

The possible economic recovery of vanadium, a mineral much in request in respect of the manufacture of a certain class of steel, from ashes of carbonaceous substances has been mooted.

Minerals Used to Harden Steel.—In respect of several minerals which until of late years were unimportant, or comparatively so, an important use has been found in connection with steel. One of these is tungsten. Tungsten metal powder is, as all metallurgists know, required for the manufacture of high-speed tools. The position in respect of tungsten is one which is at present exercising the minds of those interested in its extraction from wolfram; the business is now practically unprofitable. During the war high-speed steel was in great demand; now the demand has fallen away. Cannot new uses be found for tungsten? I have heard that the metal can be used for making piano-strings. The application of tungsten to branches of industry other than to steel offers a fruitful field for research.

I incline to the belief that, given a cheap and abundant production of some of the minor metals, uses will be found for them; and, conversely, with the discovery of uses enhanced production will be forthcoming. A case in point is the recent development in the production of stainless cutlery, which is made of chromium steel, and is in process of providing an important outlet for supplies of chromium ore.

Probably 95 per cent. of the world's production of manganese ores is used directly or indirectly in the manufacture of iron and steel. Self-hardening steels, made before the development of "high-speed tool

steels," contained from $3\frac{1}{2}$ to 4 per cent. of manganese. Nickel steels containing from 5 to 6 per cent. of manganese and from 20 to 25 per cent. of nickel have been largely used for many years for electrical resistance wires. But the output has fallen away considerably. India is now our great source of supply of manganese. The output from that country was, however, for 1919 only about five-eighths of that for 1913, and the cost of production has greatly increased owing to the increased rate of wages demanded by the native labourers. The rupee exchange and high freights also hamper the export trade. The value of the ore for metallurgical purposes, as indeed in the case of the ores of nearly all metals, depends on three factors:—

(1) The percentage of the metal contents (the metals in the case of manganese being manganese and iron).

(2) The percentage of the impurities (which in the case of manganese are phosphorus, silica, alumina, copper, cobalt, lead, zinc, barium, etc.).

(3) The physical condition in which the material is delivered to the furnace.

There are fairly extensive deposits of low-grade and impure manganese ores which research might render available, if not for metallurgical, then for chemical uses.

The position of zinc is interesting. The British zinc industry is in a very depressed state, and to this matter the Imperial Mineral Resources Bureau has been devoting much anxious thought. The Bureau was fortunate in having the benefit of the views on this subject of Mr. Gilbert Rigg and other well-known experts. Mr. Rigg, in a paper which he contributed on the subject of the position of the zinc industry at the close of 1919, points to the successful application of the electrolytic reduction of zinc ores in the face of much scepticism as to its commercial possibilities, and concludes his paper with these words:—"What is going to be the position of England's spelter industry in the next five years? If we are going to compete successfully, having regard to the high cost of fuel and materials and high cost of labour and labour difficulties, we must start to put our house in order. Fuel and labour are going up in price all over the world. The relation of labour to the general scheme of production is changing, and generating more or less friction in the process, and the successful competitors will be those who have tackled the problem of spelter production most radically and with least regard to hampering tradition." Wise words these.

Another instance of the value to the mineral industry of scientific research of possible far-reaching results may be mentioned. Mr. Picard, in his admirable presidential address to the Institution of Mining and Metallurgy in 1919, covering a wide survey of recent metallurgical progress, said:—"In the province of general metallurgy the increasing use of the Cottrell process deserves special mention. As an example of painstaking research in developing a practical process from long known, but unused, scientific fact it has few equals. We have to go back to 1870, to the work of Tyndall, for the first disclosure of the phenomenon on which the process is based. This was further examined by Frankland, Lord Rayleigh, and Oliver Lodge; but for the useful application of the principles involved we had to wait for Dr. Cottrell. He first applied the method to depositing sulphuric acid produced in the contact process, and it is still being used for this purpose. It is satisfactory to report that the merits of the invention have been recognised in this country, the first plant to be erected here in 1917 being at one of the Government acid plants. It is also in use here for the precipitation of fumes from metallurgical works, following established practice in America; its further application in this country seems certain. The advantages of the process are far-reaching; not only are valuable products recovered, but agriculture in the neighbourhood of the operations is saved from serious damage."

The Cottrell electrostatic recovery process of flue-dust and furnaces consists, as you are doubtless aware, in separating solid and liquid substances from gases in which they are held in suspension and electrically precipitating them.

There are many more fields of research on minerals which I should have liked to discuss had time permitted, such, for instance, as the extraction of aluminium from clays and from the felspar labradorite; the possible utilisation of magnesia cement for the protection of mine timber; the use of ferro-boron in making remarkably strong and tough steels; the possibility of extracting on a commercial scale potash from orthoclase felspar; the cheapening of the production of thorium nitrate from monazite—large residues of cerium compounds are obtained as a by-product, formerly regarded as useless, but now used for supplying the cerium required in the manufacture of the alloy ferro-cerium used in sparking devices—and so on. But all minerals present a field for research, and time does not permit my passing these fields in review. The few instances I have given have been selected with the view of emphasising the point I started off with, namely, that scientific research is one of the factors, and an important one at that, necessary to the development of the mineral industries and to our commercial prosperity. Much more extensive research work is necessary if we are to take full advantage of our mineral resources (with which a bountiful Providence has provided us) by rendering available ores and products therefrom which cannot now be used, and extending the use of those already in commercial consumption and producing them more cheaply.

How should research be organised and carried out? Empirical investigations must be based upon a scientific foundation if they are to be of ultimate and practical value. It has, however, been well said that if an investigator does not possess the inventive faculty as well as the purely scientific, the value of the work is apt to be largely lost. The discovery of new facts or principles is one thing, and is a characteristic of the academic type of mind, whereas the discovery of new uses for such facts or principles is another thing, and is typical of the commercial mind.

In this work of research the universities are peculiarly fitted to take an important, a leading, part. The research should not necessarily be pursued along definite lines with a definite object in view; the great discoveries were not made in that way. The Department of Scientific and Industrial Research might well endow university scientific research on chemical, metallurgical, and engineering work, supervising and co-ordinating and publishing the results. Effort is largely commensurate to the prize offered, and the discoverer should be rewarded for his labour and genius; but that would be a matter easy of arrangement. A certain amount of overlapping in scientific work is not inadvisable, but the Department would see to it that there was not undue overlapping. I offer the suggestion for what it is worth. Research associations undoubtedly perform useful, even highly valuable, functions, but the wind of science bloweth where it listeth, and the time is ripe for a realisation of the fact that scientific research cannot profitably be hampered by restrictions confining the efforts of those who are employed therein. It is of the essence of research that it should be free and untrammelled.

The Imperial Mineral Resources Bureau is not a

Bureau for research, as research is ordinarily understood, but owing to the nature and extent of the machinery which it has at its disposal, including its corresponding members throughout the Dominions and Colonies, its technical advisory committees—active bodies comprising some 151 members, who are among the leading authorities on the respective minerals and the industries connected therewith—it is in an exceptional position for disseminating suggestions, shaping problems to which they give rise, and carrying out the necessary preliminary surveys, without which it would be difficult to advise as to whether a problem should be brought before organisations such, for instance, as the Department of Scientific and Industrial Research, the province of which is the carrying out of research.

The Genetics of Sex.

By Prof. R. Ruggles Gates.

The investigation of the chromosomes in a large number of insects and other animals has shown that the so-called X- and Y-chromosomes furnish a mechanical basis for the determination of sex in the fertilised egg, its inheritance in later generations, and the usual occurrence of approximate equality of the two sexes when one of them is heterozygous (XY or XO). The fundamental character of this relation between the X- and Y-chromosomes and sex is now generally admitted. It would appear that the difference in the chromosome content of the nuclei in the two sexes affects the metabolism during development in such a way as to produce one sex or the other, and in some groups to affect the secondary sexual characters as well. Combined cytological and breeding investigations have shown further that in most insects and mammals, including man, the male is the heterozygous sex, while in the Lepidoptera and birds the female is heterozygous.

Recent work on the subject of sex in animals accepts this situation, and is building upon it a further analysis of sex-differences. The most active lines of work have been (1) in connection with the discovery and interpretation of intersexes in various animals and plants, and (2) in the explanation of the departures from equality in the numbers of the sexes under a variety of conditions, normal or experimental. It is now clear that these results do not negative a chromosome hypothesis of the fundamental distinction between the sexes, at least in animals, but rather supplement it in an important way. Sex intergrades have been studied by Goldschmidt in the Gipsy moth, by Banta in Daphnia, and by Sturtevant and others in Drosophila; also in plants there have been the studies of intersexes in Mercurialis by Yampolsky and in Plantago by Bartlett and others. These investigations are still in progress, and it is only necessary to say that they are not out of harmony with a chromosome hypothesis of the origin of the sex-differences, although the situation in plants remains to be cleared up.

Of more immediate interest here are the cases where one of the sexes preponderates. Mr. Julian Huxley (see reference in Nature, March 24, p. 116) has recently shown how in the millions fish (*Girardinus poeciloides*) a great preponderance of females, followed by a lesser preponderance of males, and finally by equality of the sex-ratio, can be best explained by assuming that the chromosome-constitution of the individual has been temporarily overridden by external influences. The important work of Riddle in controlling the sexes in pigeons may ultimately receive a similar explanation.

In an article by Mr. Alan S. Parkes (*Science Progress*, April, 1921) the author has applied somewhat similar conceptions to the explanation of the well-known departures from equality of the sex-ratios in man. The statistics from the reports of the Registrar-General, 1838–1914, show an average for this period of 1040 males to 1000 females. There is a similar preponderance of male births in most parts of the world, but in a few regions females preponderate. It is also a remarkable fact that fluctuation in the proportion of male births follows closely the rise and fall in the price of food. Statistics appear to show further a remarkable rise in the proportion of male births throughout Europe during the war, and it is suggested that war conditions were "in some obscure way beneficial to the welfare of the Y-gametes." That racial differences in the sex-ratio exist is shown by comparing Jews with Christians; it appears that the former in all countries show a greater excess of male births, while the crossing of races is also known to disturb the sex-ratios.

From a study of a number of genealogies of British families Mr. Parkes finds that families occur in which the preponderance of males is much greater than 1040 : 1000, and that this condition is inherited through the male, some strongly male-bearing strains producing more than 58 per cent. in excess of the above frequency considered as the normal.

A new type of inheritance of secondary sexual characters has recently been discovered by Schmidt (*C. r. Trav. Lab. Carlsberg*, vol. xiv., No. 8) in the fish *Lebistes reticulatus* from Trinidad. He shows that the inheritance of a black patch on the dorsal fin of the males in one race is transmitted exclusively from male parent to male offspring, never appearing in the female line at all. This is explained by assuming that the spot is determined by the Y-chromosome, for it is distributed in inheritance as the Y-chromosome is distributed. Hitherto in all cases investigated the Y-chromosome has appeared to be inactive in inheritance, the only evidence against this being the fact that males of Drosophila which lack it are sterile. The chromosomes of *Lebistes reticulatus* are now being investigated.

On the basis of this result of Schmidt, Castle (*Science*, April 8, p. 339) has built up an interesting speculation concerning the origin and relationships of the various types of sex-determining chromosomes. Briefly, his suggestion is that the X-chromosome was originally a cytoplasmic body handed on exclusively through the egg, like a plastid, and determining the female condition by its presence. This becomes included in the egg nucleus and is duplicated by splitting, thus giving rise to the condition XX in females and XO in males. If it does not split, a Y element may "develop" as its synaptic mate in the egg, passing later into male offspring, and, through non-disjunction (as in Drosophila), ultimately producing YY males which are assumed to be viable; they would give rise, as in Abraxas, to the condition in which the female is the heterozygous sex. In criticism it may be said that there is no cytological evidence of the transformation of a cytoplasmic body into a chromosome, unless the "chromatoid body" of Wilson be such a case. But it occurs in addition to the

X-chromosomes. The sex-chromosomes, it is true, frequently differ in their behaviour from the other chromosomes, but the usual assumption that the Y in insects is undergoing gradual reduction has strong evidence in its favour, and the XO condition in males can be accounted for either by its ultimate disappearance in this way or by non-disjunction. This, however, admittedly leaves unexplained the origin of the condition in moths and birds, in which the female is the heterozygous sex.

Finally, it may be added that the discovery of sex chromosomes in the liverwort Sphærocarpos by Prof. Allen (Proc. Amer. Phil. Soc., vol. lviii., p. 289) places the sex differentiation of this group of plants in a new light, and affords a basis for an instructive comparison with the conditions in animals. For a large X-chromosome is found in the nuclei of the female gametophyte, and a small Y in the cells of the male gametophyte. The fertilised egg then contains an X and a Y, which are separated in sporogenesis. Half the spores contain an X and half a Y. This is quite different from the situation in insects where the XY combination produces a male. It is also simpler, the differentiation of the sexes arising through segregation of the X and Y, and the chromosome combination of the sporophyte corresponding to that of males in animal species in which the male is the heterozygous sex.

University and Educational Intelligence.

CAMBRIDGE.—Mr. P. Lake, St. John's College, has been reappointed to the Royal Geographical Society's readership in geography; Dr. J. A. Crowther, St. John's College, appointed University lecturer in physics as applied to medical radiology; and Mr. S. E. Hollingworth, of Clare College, elected to the Harkness scholarship in geology. The Wiltshire prize in geology has been awarded to Mr. A. G. Brighton, Christ's College, and Mr. H. C. G. Vincent, Fitzwilliam Hall.

Mr. W. Campbell Smith and Mr. R. H. Thouless have been elected fellows of Corpus Christi College.

LIVERPOOL.—Dr. McLean Thompson, of the University of Glasgow, has been appointed to the Holbrook Gaskell chair of botany in succession to Prof. R. J. Harvey-Gibson, resigned.

LONDON.—At a meeting of the Senate held on June 22 Sir Sydney Russell-Wells was re-elected Vice-Chancellor for the year 1921–22.

Dr. G. Cook was appointed to the University chair of mechanical engineering tenable at King's College, and Mr. L. Hawkes to the University readership in geology at Bedford College. The title of emeritus professor of philosophy and comparative psychology in the University was conferred on Mr. Carveth Read.

Grants were made from the Dixon Fund to Mr. F. J. F. Barrington, Mr. E. J. Evans, Prof. J. P. Hill, Miss G. Z. L. Le Bas, Mrs. M. M. Neilson-Jones, Prof. Karl Pearson, Mr. J. W. D. Robinson, Mr. D. M. Shaw, Mr. H. G. Smith, and Miss D. M. Wrinch.

The following doctorates were conferred :—*D.Sc. in Zoology:* Mr. W. A. Cunnington. *Ph.D. in the Faculty of Economics:* Mr. S. G. Panandikar. *Ph.D. in the Faculty of Science:* Mr. H. E. Cox and Mr. H. H. Morgan.

MANCHESTER.—The sum of 1000*l*. has been contributed to the appeal fund by Alderman H. Plummer.

OXFORD.—On Wednesday, June 22, the honorary degree of Doctor of Science was conferred on Prof. C. S. Sherrington, president of the Royal Society.

IT is announced that Mr. F. S. Edie, lecturer in biochemistry at Aberdeen University, has been appointed to the chair of biochemistry in the University of Cape Town.

M. E. DEUTSCH DE LA MEURTHE has made a donation of 10,000,000 francs to the University of Paris to provide for a university quarter where students may live at a moderate cost.

MR. W. J. JONES, senior lecturer in chemistry in the University of Manchester, has been appointed professor of chemistry in the University College of South Wales and Monmouthshire, Cardiff; and Prof. A. W. Sheen, of the Welsh National School of Medicine, to the chair of medicine at the same institution.

THE Aitchison memorial scholarship of the value of 36*l*., tenable in the full-time day courses in technical optics at the Northampton Polytechnic Institute, Clerkenwell, is being offered. The examination for the scholarship, open to both sexes, will be held on September 27 and 28. Full particulars can be obtained from Mr. H. F. Purser, 35 Charles Street, Hatton Garden, E.C.1.

Two scholarships, each of the value of 200*l*., are being offered by the Rubber Advisory Committee of the Northern Polytechnic Institute, Holloway, to enable students who have obtained a good degree in chemistry to attend for a year's special training in rubber technology. Applications, with particulars of the candidates' careers, copies of recent testimonials, and names of referees, must be sent to the Principal of the institute not later than July 5.

THE announcement which appeared in the daily Press last week of the retirement of Prof. Henri Bergson from his chair at the Collège de France merely meant to his friends that he had at last given effect to an intention long contemplated. Owing to the strain of the international work which he undertook for the French Government with such fervour during the critical years of the war, he was compelled to avail himself of the privilege which the Collège allows its members of nominating a deputy, and for some time past M. Edouard Le Roy has occupied his place in the lecture-room. Now that Prof. Bergson is able to take up again the interrupted work of philosophy, he finds that he can hope to do original research only by obtaining relief from the routine work of lecturing. This, and nothing else, is the reason of the resignation which is now announced. The Collège de France, in which Prof. Bergson has held the chair of philosophy for more than twenty years, is a unique institution. Founded by Francis I. in 1530, in opposition to the Sorbonne and the universities, it has retained its high position and character. It is perhaps the only educational institution which survived the Revolution unchanged. Its lectures are without exception open to the public and free. Even a registered student cannot obtain the privilege of a reserved seat. When a professorial chair becomes vacant the successor is elected by the professors, who are not handicapped in their choice by academical regulations of any kind. The appointment entails the duty of delivering two courses of lectures in each session, neither of which may be a repetition of a course previously delivered either in the Collège or elsewhere.

Calendar of Scientific Pioneers.

June 30, 1817. Abraham Gottlob Werner died.—The most renowned geologist of his day, Werner for forty years was professor in the Mining School at Freiburg, which became under him "the European lodestar for the study of mineralogy and geognosy."

June 30, 1857. Alcide Dessalines d'Orbigny died.—Distinguished in early life for his journeys in South America, d'Orbigny in 1840 began the publication of his great work, "Paléontologie Française." In 1853 a chair of palæontology was specially created for him at the Musée d'Histoire Naturelle.

June 30, 1919. John William Strutt, third Baron Rayleigh, died.—Born in 1842, Lord Rayleigh succeeded to the title in 1873. He was educated at Cambridge, succeeded Maxwell in 1879 as Cavendish professor of experimental physics, and in 1887 followed Tyndall as professor of natural philosophy at the Royal Institution—a position he resigned in 1905. His scientific writings embrace every branch of physics, and are known for their extreme accuracy and definiteness. His name is associated with that of Ramsay in the discovery of argon.

July 1, 1881. Henri Etienne Sainte-Claire-Deville died.—Professor of chemistry at the Ecole Normale and in the Sorbonne, Sainte-Claire-Deville carried out important investigations on dissociation.

July 1, 1899. Sir William Henry Flower died.—Flower was Hunterian professor of comparative anatomy and physiology, and for fourteen years acted as director of the British Museum (Natural History).

July 2, 1621. Thomas Harriot died.—The contemporary of Napier and Briggs, Harriot made important improvements in algebra, and his "Artis Analyticæ Praxis," published ten years after his death, did much to bring analytical methods into general use.

July 3, 1672. Francis Willughby died.—An original member of the Royal Society, Willughby was the companion of Ray, and wrote on birds and fishes.

July 4, 1850. William Kirby died.—Rector of Barham, in Suffolk, from 1796 to 1850, Kirby was known for his writings on entomology.

July 4, 1901. Peter Guthrie Tait died.—Tait succeeded Forbes in the chair of natural philosophy at Edinburgh. He was known for his collaboration with Lord Kelvin, his advocacy of quaternions, and his work on thermodynamics and other subjects.

July 4, 1902. Hervé Auguste Etienne Alban Faye died.—President of the Bureau des Longitudes from 1874 to 1893, Faye in 1884 published his "Sur l'Origine du Monde."

July 4, 1910. Giovanni Virginia Schiaparelli died.—A great observer of comets, meteors, double stars, and especially of the planets, Schiaparelli from 1862 to 1900 directed the Milan Observatory.

July 5, 1833. Joseph Nicéphore Niepce died.—One of the pioneers in photography, Niepce began his experiments in 1813. He afterwards collaborated with Daguerre.

July 5, 1859. Baron Charles Cagniard de la Tour died.—Cagniard de la Tour made improvements in mechanical and chemical processes and invented the siren.

July 5, 1906. Paul Drude died.—A distinguished physical investigator, Drude applied the theory of Maxwell as developed by Hertz to the problem of light. He edited the *Annalen der Physik*.

July 5, 1911. George Johnstone Stoney died.—Stoney held important educational posts in Ireland, and contributed to physical optics and molecular physics. To him we owe the term "electron."

E. C. S.

Societies and Academies.

LONDON.

Royal Society, June 23.—Prof. C. S. Sherrington, president, in the chair.—E. F. **Armstrong** and T. P. **Hilditch**: A study of catalytic actions at solid surfaces. VI.—Surface area and specific nature of a catalyst: two independent factors controlling the resultant activity. The influence of the surface area of a nickel catalyst on its activity has been traced by examination of the bulk gravity of various types of catalyst: the most efficient catalyst occupies the greatest volume per unit mass. The rate of reduction in hydrogen of nickel oxide prepared in various ways has been examined at various temperatures. A light nickel oxide prepared from the precipitated hydroxide gave curves (hydrogen consumption/time) showing faint points of inflexion, which varied with the temperature of reduction; dense, fused nickel oxide gave a smoother curve, and nickel hydroxide deposited on kieselguhr as a support showed a smooth, continuous curve. The reduction curves are related to the physical conditions rather than to the formation of any definite compounds. When a support (kieselguhr) is overloaded with nickel hydroxide and reduced so that varying proportions of the nickel are in the metallic state, catalytic activity increases rapidly to a maximum, which is maintained until all the nickel hydroxide has been reduced to the elementary state. Catalytic activity is dominated by the condition of the surface layer of reduced nickel.—Sir J. B. **Henderson**: (i) A contribution to the thermodynamical theory of explosions; (ii) with Prof. H. R. **Hassé**. Advances in chemical thermodynamics, dealing with dissociation of gases and variation of their specific heats with temperature, are applied to the science of internal ballistics. Direct experiments on specific heats of gases are limited to temperatures below 1500° C., and extrapolation, based upon thermodynamic theory and extending to temperatures of 3500° C. and to pressures of 20 tons per sq. in., tests the theory severely. Part (i) contains the application of these theories to the calculation of the explosion-pressure of cordite in closed vessels, and the calculation of the curve of adiabatic expansion of the products of explosion by considering a series of states of equilibrium and, following thereon, the ideal indicator diagram of a gun. In part (ii) the curve of rise of pressure and the maximum pressure allowing for burning of cordite in parallel layers and for varying capacity of chamber during burning, due to movement of the projectile, are calculated. The results enable the indicator diagram of gun, maximum pressure, and muzzle velocity of projectile to be calculated accurately from the chemical composition of explosive used and rate of burning of the cords. They also show the effects produced by variations in initial pressure, density of loading, temperature of charge, diameter of cords, etc. The method is also applicable to internal-explosion engines using gas or oil.—S. **Butterworth**: Eddy current losses in cylindrical conductors, with special applications to the alternating current resistances of short coils. A general series for the eddy current losses produced in a non-magnetic metallic cylinder when placed in a transverse field of any form is developed. The theory gives an approximate solution of the problem of the effective resistance of two equal parallel wires carrying equal currents either in the same or in opposite directions. The "uniform field" theory is applied to determine the effective resistance of parallel wire systems, and, by calculating the mean square field acting throughout the section of the coil, formulæ are obtained for the effective resistances of single- and multi-layer sole-

noidal coils of either solid or stranded wire. Conditions producing the maximum value of L/R′ for a given length of wire of given diameter are deduced. The observed inferiority of stranded wire coils as compared with solid wire coils at high frequencies is due to the lack of internal spacing of the strands of the coils making the best conditions unattainable. —E. S. **Bieler**: The currents induced in a cable by the passage of a mass of magnetic material over it. The mass used is in the form of a spherical shell, and the deflection of a critically damped galvanometer in series with the cable is deduced. The results agree with those of experiments carried out in the laboratory on a small scale. The theoretical results are used to determine the law of variation of the galvanometer with different factors, and the relation between the galvanometer deflection and the E.M.F. which produces it.—Dr. G. **Barlow** and Dr. H. B. **Keene**: The experimental analysis of sound in air and water: some experiments towards a sound spectrum. The original sound vibration gives rise to an electric current of telephonic magnitude, which is analysed by a method of periodic interruption. A motor-driven interrupter with a range of interruption frequency from 3–2000/sec. is placed in series with a Broca galvanometer in the circuit containing the alternating current to be analysed. The speed of the interrupter is then slowly varied. When the interruptions synchronise with any component of the current, the galvanometer gives a steady deflection, the magnitude of which depends on the phase difference. Thus the amplitude of each component may be determined, and at the same instant the corresponding frequency is observed stroboscopically. Experiments were made (1) to test the trustworthiness of the method by analysing alternating currents containing known constituents; (2) to analyse different types of sound in air, using both carbon microphone and magnetophone receivers; (3) to analyse sounds in water. The variations of the sound spectrum with distance, depth, and direction are investigated, and the spectrum of a motor-driven boat is obtained under various conditions.—Dr. G. **Barlow**: The theory of the analysis of an electric current by periodic interruption. A mathematical treatment of the method of periodic interruption used in the experimental analysis of sounds described in the previous paper is given, with an explanation of the effects of periodic interruption on the intensity and quality of sounds heard in a telephone.

Geological Society, June 8.—Mr. R. D. Oldham, president, in the chair.—Dr. W. F. **Hume**: The relations of the northern Red Sea and its associated gulf-areas to the "rift" theory. The areas specially considered are the northern portion of the Red Sea and the "Clysmic Gulf" (from "Clysma," the Roman name for Suez), defined as the district lying between the fault-bounded ranges of Egypt and Sinai. Within its borders Miocene deposits are of wide distribution; beyond them they are absent. The folds within this region are from north-west to south-east, outside it the trend is frequently almost at right angles. A line prolonging the direction of the western coast of the Gulf of Akaba to the shores of Egypt divides the Clysmic Gulf from the Red Sea, the former being one of complicated fold-and-fracture effects, while in the latter only fold effects have been observed. It is concluded that the whole region underwent extremely slow submergence, the negative movements continuing from early Jurassic to late Cretaceous times. Emergence of new land probably took place near the close of the Eocene period. It is suggested that the area was occupied by an anticline plunging northwards in the Clysmic Gulf region, and that it was subject first to marine and then to subaerial erosion. This formed part of the continent on which grew the trees of the Petrified Forest, and on which wandered animals such as the Arsinoitherium and the earliest elephants. The continental period was most marked during late Eocene and early Miocene times, and the area dealt with here appears to have become one of very varied ridge and depression. The whole region was slowly invaded by the ancient Mediterranean during the Miocene and Pliocene periods. The pre-existing ridges became coral-reef centres and the intervening depressions were filled up, first by land-derived deposits and then by lagoon formations. The earliest of these formations appear to have been of Schlier (Middle Miocene) age. The whole region of the Clysmic Gulf became folded and fractured. There is strong faulting at the borders with the igneous hills, and fold-ranges are of asymmetrical anticline type. Compression of the area, with uplift of portions, offers the best solution for the fact observed. Dislocation so marked and so widespread could scarcely arise under rift formation as defined by Prof. J. W. Gregory, nor can the whole of the surface-differences be ascribed to erosion. No simple solution of the problem can be offered on the evidence at present available, especially in view of the fact that no important faulting has been noted on the western borders of the Red Sea. The portion of the Nile Valley about latitude 26° N., where faulting is most conspicuous, may have been initiated by erosion of a sharp anticlinal fold due to the compression of almost horizontal strata. Sharp folds exist in the desert east of the Nile, but their origin is doubtful.

Physical Society, June 10.—Dr. C. Chree, vice-president, in the chair.—Sir Ernest **Rutherford**: The stability of atoms. Traces of hydrogen and helium had been found in discharge tubes believed to be initially free from these gases; but it was impossible to establish that no source of contamination was available. It is necessary to attack the nucleus of the atom, and to do this successfully requires extremely swift particles. The effects produced when α-particles fired through hydrogen collide with an atom were shown, and experiments were described from which the conclusion had been drawn that when an α-particle collides with a nitrogen atom, a hydrogen atom is expelled from the nucleus. The speed of these is in excess of what can be obtained by collisions in hydrogen gas itself, so that the result must be due to the disintegration of the nitrogen nucleus rather than to contamination with hydrogen. Results on the disintegration of aluminium and other elements were also indicated.

Linnean Society, June 16.—Dr. A. Smith Woodward, president, in the chair.—Prof. A. H. R. **Buller**: The ocellus function of the subsporangial swelling of Pilobolus. The subsporangial swelling of Pilobolus functions as a squirting apparatus, and also as an ocellus, which receives the heliotropic stimulus which causes the stipe to turn the fungus gun towards the light. The swelling is transparent and refracts light. It appears to be the only orthoheliotropic plant organ known which has a special light-perceiving cell-structure, which is sometimes described as a simple eye.—Dr. N. **Annandale**: The vegetation of an island in the Chilka Lake. The area of the island is about one-third of a square mile, and the rocks are composed of garnet-bearing quartzite which yields an infertile and scanty soil on weathering. The climate is relatively dry. The vegetation consists mainly of trees, shrubs, and perennial creepers, with a great scarcity of herbs, ferns, and epiphytes, and a complete absence of palms, bamboos, screw-pines, and

orchids. Several distinct zones of vegetation can be distinguished. The peculiarities of the fauna can be correlated directly with the vegetation.—Col. M. J. **Godfery**: The fertilisation of the orchid genus Cephalanthera. The author holds that Cephalanthera is an old genus, and was not derived from Epipactis.

Paris.

Academy of Sciences, June 6.—M. Georges Lemoine in the chair.—The president announced the death of M. J. B. A. Gaillot, correspondant for the section of astronomy.—G. **Friedel**: The calculation of the intensity of X-rays diffracted by crystals: A correction.—S. **Pincherle**: An integral equation in the complex domain.—B. **Gambier**: Applicable surfaces and the equation of Laplace.—M. **Auric**: The theory of ideal algebraical numbers.—A. **Tian**: The stability and the reversibility of the transformations of the hydrosols obtained by the hydrolysis of salts.—Mlle. **Wolff**: Studies on the molecular refraction and specific rotatory power of furfuralcamphor and some of its derivatives.—Mlle. S. **Veil**: Allotropic varieties of oxides. The conductivity of various metallic oxides measured at varying temperatures has been shown to increase with the temperature, similarly to electrolytes. Magnetic iron oxide and cadmium oxide offer peculiarities, since the conductivity-temperature curves for these show points of inflection. These changes can be attributed to the formation of allotropic forms of the oxides.—C. **Chéneveau**: The variation of the specific refraction of dissolved salts in dilute solution. A study of the specific refraction of dilute solutions of ammonium nitrate, potassium chloride, and magnesium nitrate.—M. **Billy**: The peroxide of titanium. The hydrates of titanium, hitherto regarded as derived from the oxide TiO_3, are shown to be complexes of hydrogen peroxide and the peroxide Ti_2O_5.—E. **André**: Contribution to the study of the oils from grape-seeds.—J. **Martinet** and O. **Dornier**: Some new sulphonic derivatives of oxindol and of isatin.—A. **Mailhe** and F. **de Godon**: The preparation of mixed secondary and tertiary phenolic amines. The vapours of aniline and ethyl alcohol passed over alumina at 350° to 380° C. gave a mixture of mono- and di-ethylanilines. The method is shown to be of general application.—F. **Zambonini**: The palmierite of Vesuvius and the minerals which accompany it.—M. **Romieux**: The controversy as to the displacement of shore levels and the phenomena of equideformation.—J. **Cvijić**: Relief of the seashore and river terraces.—A. **Carpentier**: Discovery of a Weald flora in the neighbourhood of Avesnes.—P. **Schereschewsky**: Systems of clouds. Suggestions for a new system of cloud observations. Different states of the sky should be observed simultaneously from a number of stations spread over a wide area.—O. **Mengel**: Influence of the relief and of the heating of the soil on surface winds.—M. **Bridel** and R. **Arnold**: A method allowing the application to plants of the biochemical method of detecting glucose. The method is based on the property possessed by emulsin of causing the combination of glucose with the alcohol holding it in solution. Full details of the technique of extraction and purification of the plant product before submitting it to the action of the emulsin are given. —N. T. **Giung**: The botanical determination of foreign beans.—G. **Bioret**: The Graphideæ.—E. **Chatton**: False and true myogenesis in the pelagic Copepods. An error due to the non-recognition of cœlomic parasitic Peridinians.—C. **Pérez**: A supposed interstitial tissue in the testicle of lizards. A criticism of a recent communication on the same subject by M. Christian Champy.—H. **Bierry** and F. **Rathery**: Liver, blood plasma, and proteid sugar. The authors point out what they believe to be a function of the liver not hitherto noted, a qualitative and quantitative change in the composition of the blood plasma after passing through the liver.—J. P. **Langlois**: A moving belt for the study of walking and of work. A modification and improvement of a similar apparatus set up by Benedict at Washington.—MM. H. **Vallée** and **Carré**: Anti-aphthous hæmo-prevention and hæmo-vaccination.—G. **Bourguignon**: Chronaxy in neuro-muscular Wallerian degenerescence in man.

New South Wales.

Linnean Society, April 27.—Mr. G. A. Waterhouse, president, in the chair.—G. I. **Playfair**: Australian fresh-water flagellates. An account of the forms known from collections made in the neighbourhood of Sydney and Lismore. Mention is made of 172 forms representing 39 genera, of which 96 forms and 1 genus are new.—Dr. R. **Greig-Smith**: Note upon the extraction of acids from cultures. In testing the products of fermentation of dextrose by a film yeast, succinic acid was obtained as the only fixed acid. The extraction of the fixed acids from bacterial or from yeast cultures is a monomolecular reaction. The preparation of salts by neutralising the acids until a pink colour is obtained in the presence of phenolphthalein may be faulty because the reaction is slower than is generally supposed.—Dr. A. B. **Walkom**: The occurrence of Otozamites in Australia, with descriptions of specimens from Western Australia. Three species of Otozamites and some obscure coniferous remains are described from near Mingenew. The rocks in which they occur consist of dark red ferruginous sandstone, which, with its wide distribution, constitutes an important stratigraphical horizon, and probably indicates a warm, moist climate for northern Australia in Jurassic time.

Books Received.

Le Mouvement scientifique Contemporain en France. No. 1: Les sciences naturelles. By Dr. G. Matisse. Pp. 160. (Paris: Payot et Cie.) 4 francs.

Relations intellectuelles avec les Centraux? "Ecrasons l'Infâme." By Maurice Lecat. Pp. viii+128. (Louvain, Ave. des Alliés 92; Bruxelles, Ave. bois Cambre, 16: The Author.)

Faune de France. By P. Paris. No. 2: Oiseaux. Pp. iv+473. (Paris: P. Lechevalier.) 40 francs.

Handbook of Chemistry and Physics: A Ready-Reference Pocket Book of Chemical and Physical Data. By Prof. C. D. Hodgman and others. Eighth edition. Pp. 711. (Cleveland, Ohio: Chemical Rubber Co.) 3 dollars.

Imperial Institute: Indian Trade Enquiry. Reports on Timbers and Paper Materials. Pp. ix+57. (London: J. Murray.) 4*s.* net.

Psychoanalysis, Sleep and Dreams. By André Tridon. Pp. xiii+161. (London: Kegan Paul and Co., Ltd.) 7*s.* 6*d.* net.

Diary of Societies.

THURSDAY, JUNE 30.

INSTITUTION OF CIVIL ENGINEERS (Engineering Conference), at 10 a.m.—W. W. Grierson: The Use of Reinforced Concrete on Railways.—H. J. Fereday: Impact Tests and Allowances.—A. H. Hall: The Influence of the Automatic and Semi-automatic Machine on the Skill and Resourcefulness of the Mechanic and Operator.—A. Musker: Mechanical Appliances and Labour in Loading and Unloading Ship's Cargoes.—Prof. W. E. Dalby: The Elastic Limit.—Prof. E. G. Coker: The Effect of Scratches in Materials.—C. P. Sandberg: Damage to Tires and Rails caused by Brakes or Slipping Wheels.—G. Hatton: The Existing Practice of Inspecting Work and Materials.—M. E. Denny: The Design of Fabricated Ships from the Labour-saving Point of View.—J. C. Telford: Economy of Labour on Shipbuilding as effected by Fabricated Ships, etc.—E. R. Mumford: Recent Tank Research in Screw Propellers.—E. H. Richards and M. G. Weekes: Straw Filters for Sewage-purification.—J. Haworth: Activated Sludge.—J. D. Watson: De-watering Sludge.—J. Dalziel: Battery Locomotives.

INSTITUTION OF MECHANICAL ENGINEERS, at 10.15 a.m.—Conference on the Means of Improving the Thermal Efficiency of Heat Power Plants.—H. E. Wimperis: Internal-combustion Engine Theory, with relation to Higher Economy.—F. Samuelson: High Steam-Pressure and other Means of increasing Economy of Steam-Engines.—E. V. Evans: Chemistry of Combustion.—A. Hutchinson and F. Bainbridge: Blast-Furnace Gases.—D. Wilson: Boiler-House Management (General Causes of Boiler Inefficiency).—Prof. W. A. Bone: Low Temperature Carbonisation.—H. Dunell: Engine-House Management (General Causes of Steam-Engine Inefficiency).—A. E. L. Chorlton: Super-Compression.

ROYAL SOCIETY, at 4.30.—Sir J. J. Dobbie and Dr. J. J. Fox: The Absorption of Light by Elements in a State of Vapour. The Halogens.—Prof. W. A. Bone and the late W. A. Haward: Gaseous Combustion at High Pressures. Part II. The Explosion of Hydrogen-Air and Carbon-monoxide-Air Mixtures.—Prof. A. E. H. Love and F. B. Pidduck: Lagrange's Ballistic Problem.—J. Proudman: The Principles of Internal Ballistics.—R. H. Fowler: A Simple Extension of Fourier's Integral Theorem and Some Physical Applications in particular to the Theory of Quanta.—Capt. D. Brunt: The Dynamics of Revolving Fluid on a Rotating Earth; and other papers.—The following papers will be read in title:—Takeo Shimizu: A Preliminary Note on Branched α-ray Tracks.—Takeo Shimizu: A Reciprocating Expansion Apparatus for detecting Ionising Rays.—Prof. R. W. Wood: The Time Interval between Absorption and Emission of Light in Fluorescence.

FRIDAY, JULY 1.

INSTITUTION OF CIVIL ENGINEERS (Engineering Conference), at 10 a.m.—R. G. H. Clements: Road Vehicles and their Relation to Road Surfaces.—A. Dryland: Advantages of Bituminous Macadam.—C. H. J. Clayton: The Conservancy and Maintenance of Rivers from the Point of View of Land Drainage.—R. F. Grantham: The Effect of Sluices and Barrages on the Discharge of Tidal Rivers.—G. E. W. Cruttwell: The Utility of Models for Estuarial Experiments.—H. C. Reid: The Relative Advantages of Dredging and Training-walls in Estuaries.—E. Latham: The Use of Inertia Gauges in Pile Driving.—A. L. Bell: The Bearing Power of Soils.—Sir James McKechnie: Internal-combustion Engines with Large Cylinders.—Sir Vincent L. Raven: The Mechanical Advantages of Electric Locomotives compared with Steam.—T. Crook: The Effect of the War on Mineral Supplies.—M. Deacon: The Utilisation of Exhaust Steam in Turbines.—W. C. Mountain: Steam *versus* Electric Winding.—S. Cowper-Coles: The Relative Values of Protective Metallic Coatings for Iron and Steel.—J. Richardson: Recent Progress in Large Diesel Engines for the Mercantile Marine.—R. J. Walker and S. S. Cook: Experience with Marine Turbine Reduction-gears.—E. Sandeman: Compensation Water.—F. W. Macaulay: Pipes for Pressure Conduits.—Dr. H. Lapworth: The Relation of Run-off to Rainfall.—Economic Limits of Distribution from Coal-fired Stations.—B. Welbourn: Low-voltage Overhead Distribution.

INSTITUTION OF MECHANICAL ENGINEERS, at 10.30 a.m.—Conference on the Means of Improving the Thermal Efficiency of Heat Power Plants.—R. Nelson: Waste-Heat Utilisation.—Sir Henry Fowler: Superheating.—Dr. W. R. Ormandy: Liquid, Colloidal, and Powdered Fuels.—H. Moore: Liquid Fuels (Internal-combustion Engines).—A. W. Bennis: Automatic Stokers.—W. H. Patchell: Air Heating for Boiler Furnaces.—C. E. Stromeyer: Feed-Heating and Economisers.—Prof. W. E. Dalby: The Indicator as an Aid to Economy.

GEOLOGISTS' ASSOCIATION (in Architectural Theatre, University College), at 7.30.—H. Bury: Some High-level Gravels of North-East Hampshire.

MONDAY, JULY 4.

ROYAL BOTANIC SOCIETY OF LONDON, at 3.—Prof. A. R. Bickerton: The Generic Simplicity and Great Importance of Basic Principles in all Scientific Work. (1) The General Graphics of Science.

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

ARISTOTELIAN SOCIETY (at University of London Club, 21 Gower Street), at 8.—Dr. F. C. S. Schiller: Arguing in a Circle.

WEDNESDAY, JULY 6.

ROYAL SOCIETY OF MEDICINE (Annual General Meeting), at 5.—Presentation of Gold Medal to Sir Almroth Wright.

THURSDAY JULY 7.

MEDICO-LEGAL SOCIETY (Annual General Meeting) (at 11 Chandos Street, W.1), at 8.30.—Prof. A. Louise McIlroy: Some Factors in the Control of the Birth-rate.

CONTENTS.

THURSDAY, JULY 7, 1921.

Internationalism.

At the outbreak of war in 1914 it was widely proclaimed that the Allies were fighting for the integrity of small nations. The war was fought and won to no small extent through appeal to the spirit of nationality. At the time of the Armistice small peoples sprang up here and there—as, for instance, in the Caucasus—clamouring for "the recognition of their national aspirations"; and the minor wars and disputes which have followed have arisen largely from the encouragement afforded to national ambitions by the attempt to fix boundaries or to allocate territory in those areas in which "ethnological affinities" are uncertain or the distribution of races is ill defined. Concomitantly with this quickened sense of nationality there grew up an idea which is necessarily, to some extent, in conflict with it. The desire to avert the recurrence of a catastrophe which rapidly assumed such proportions as to imperil the whole world turned the thoughts of men to the conception of an international union which should exercise such control over its members as to prevent precipitancy in action and in the ultimate resort be in a position to exert such force as to check an appeal to the arbitrament of war.

In a sense, the League of Nations represents a compromise between the two ideas. It aims at a comity of nations without undue interference with the sovereignty of the constituent States. Springing from a desire that the war should end war, to use the common phrase, the League has become an expression of a broader humanitarian ideal. The duties of the mandatory Powers are a "sacred trust," and this spirit animates the whole conception. The more influential supporters of the League, in this country at least, have approached the problem in no doctrinaire spirit. They recognise that progress must be slow, and that the keystone of success lies in the education of the peoples of the several States, upon whom the continued existence of the League must ultimately depend. The fact that members of the League have transgressed both the spirit and the letter of the Covenant does not necessarily condemn the League. Its position is not yet sufficiently assured to resist the stress of abnormal conditions.

To Mr. H. G. Wells, however, the League of Nations merely represents a number of vague movements for a world-law, world-disarmament, and the like among intellectuals; and in his work, "The Salvaging of Civilization," he proposes a different type of international unity. Holding that there cannot be any world-control without a merger of sovereignty, he plumps boldly for a world-State as the sole possible preventive of a series of wars which will come to an end only when knowledge has perished and we have sunk into a state of barbarism. To avoid this contingency, or rather certainty, Mr. Wells would arouse in mankind a recognition of the fact that the world has become one community, and as such should be regulated by a world-law. That such an attitude of mind is not an impossible ideal is indicated by the feeling which was aroused even in the remotest parts of the world by ex-President Wilson's first proposal for a League of Nations. To attain this acceptance of a world-law Mr. Wells relies upon education, particularly of the young, in accordance with a scheme which he has sketched in outline.

While in many respects this scheme of education may be suitable for a highly civilised Western people, it ignores differences of outlook and culture. "Schooling," says Mr. Wells, "is, in fact, . . . the expansion and development of the primitive savage mind, which is still all that we inherit, to adapt it to the needs of a larger community." This statement is at best but a half-truth. The highly civilised races of Europe and America have centuries of development behind them, and notwithstanding the "speeding up" which has become possible with the development of modern conditions, the less advanced races, even of parts of Europe, such as the Balkan Peninsula, are not likely to assimilate these ideals for some time to

come, while in the case of the really backward races the premature application of modern culture and educational methods would spell disaster. Wise supporters of the League of Nations do, at any rate, recognise that part of the "sacred trust" of a mandatory Power is to provide for the education and training of the races under its tutelage on lines suitable to their stage of development.

Criticism of any scheme of internationalism is easy, and the difficulties which have to be overcome are enormous. The verdict of history on the whole is adverse. But against this must be set the fact that the world has never been faced with conditions similar to those of to-day, or with the possibility of a crisis such as would be involved in another war. Is the realisation of the danger which threatens civilisation strong enough to overcome the jealousies, the bickerings, and the rivalries of States which are loosely joined in a confederation, or even united under a "world-law"? Present conditions are not favourable to the probability of success. Although we may speak of nations as if they were individuals, one of the strongest of social forces which operate in the case of the majority of the individual members of a community is absent. Nations, like corporations, have no conscience, and the force of the moral judgment and the opinion of others is not operative. Whereas in a civil society public opinion largely determines conduct and force is the ultimate sanction, in a confederacy of nations force is the only sanction. The balance of power alone will influence any member or group of members who may wish to defy the body as a whole.

It is no answer to criticism to say that in a world-State, or in the conditions of international amity towards which the supporters of the League of Nations would wish to progress, such occasions for misunderstanding would not arise. Apart from the differences in degree of culture, there is among nations as they exist to-day a variety in outlook which is the outcome of history, tradition, education, and environment. The effect of this variety in outlook was patent to those who, during the war, took part in operations with the composite armies which fought on some of the Allied fronts. The outward semblance of unity of action was attained only by a constant smoothing away of difficulties and misunderstandings arising out of national differences of temperament and outlook.

Differences of temperament are easy to note, but difficult to reduce to a scientific formula. Nor do we know how far they are fundamental and ineradicable. The comparative study of racial psychology on modern scientific lines is almost an unexplored field. National character, in so far as it is the product of tradition and education, may be susceptible of modification. Most nations to-day are the result of a fusion of races the members of which live more or less in amity, and this lends support to the view which holds to the ultimate possibility of a wider unity. Against this, however, must be set the view of some anthropologists who are inclined to attach increasing importance to race as a persisting element in character. In this country, for instance, notwithstanding common environment, common tradition, and common institutions, differences of occupation and of class feeling seem, in a general way, to go with differences of racial type. Should a more extended observation tend to confirm this view, it would suggest that any form of international confederation which aims at obliterating nationality and race would scarcely attain enduring success.

What Relativity in Science Implies.

The Reign of Relativity. By Viscount Haldane. Pp. xxiii+430. (London: John Murray, 1921.) 21*s.* net.

THERE is no need to begin this notice of Lord Haldane's book with a general reference to its scope and purpose. It is well known that, though the book deals with many problems of science, it is not scientific in the technical meaning of the term; it is philosophy, and, as philosophy, it includes every realm of human experience, and, therefore, science, in its synopsis. It will be more interesting to readers of NATURE to select certain particular problems of science which are also problems of philosophy.

The first part of the book deals mainly with the principle of relativity, the metaphysical basis of which is brought out with wonderful clearness. Lord Haldane achieves this, not so much by his direct exposition, which is thorough, as by his delicate and subtle critical comparison of two methods of applying the principle in mathematics and physics, that of our English mathematician, Prof. Whitehead, and that of Einstein himself. His exposition of both these writers is masterly. The chapter on Einstein is the clearest account of his theory and method that has yet appeared; possibly it appears clearer than it otherwise would from the fact that it follows the account of Whitehead, which is certainly more difficult. This does

not mean that Lord Haldane's exposition has made either writer easy to understand, but it has made it possible for anyone who cares to give the necessary attention and concentration to understand them both. Those who have argued *a priori* that any exposition of the principle of relativity by Lord Haldane must be defective and inconclusive because he is not a mathematician and therefore does not use or know how to use the language which enables mathematicians to express their equations have only shown that they mistake both the purpose and the nature of the value of mathematical methods. It is just because mathematics is restricted to abstract quantitative measurements that its system of symbols is so effective an instrument. Mathematicians are the first to acknowledge this. They know it is they who are handicapped when it comes to laying bare the metaphysical concept, handicapped by the very ease with which they are able, by the manipulation of symbols, to simplify the most complex and complicated quantitative equations.

When we say of anything that it is relative, the question immediately follows: Relative to what? Absolute relativity is either a contradiction in terms, as if one should say a round square, or it is an expression for that extreme form of scepticism which professes to be a universal negation. Now, undoubtedly the first impression we receive of the general principle of relativity does dispose us to identify it with the principle of universal doubt. On this aspect of the great problem Lord Haldane is clear and pronounced from the first sentence of his preface to the end of his book. To the question, Relative to what? he replies, Relative to knowledge; and knowledge is not itself an abstract relation, but a concrete universal. In this he is following Hegel, who first brought to light, in its modern form, the dialectical nature of thought. "Knowledge," says Lord Haldane, "is dynamic. It is an effort to transcend the apparently given. It is always pointing beyond itself" (p. 140). It is from this point of view that the comparison of Whitehead and Einstein is instructive. Both are concerned, and concerned only, to present to us a science of Nature. Both reject the absolute: there is neither a space-time system nor a material, dependent or independent of the observers attached to it, which can serve as a norm by which to regulate the relations of different space-time systems. Both reject the principle of action at a distance: it is inconceivable as fact and useless as a principle. An interesting, though perhaps a minor, point in which Lord Haldane notes a difference between them is that, while for Whitehead the element out of which our concept of Nature is constructed is the event, and the object is a derivative notion, for Einstein the event seems to depend on the notion of object. In this Lord Haldane thinks Whitehead is more faithful than Einstein to the fundamental principle of the four-dimensional space-time continuum. Apart from this, it is Einstein who has made the greater advance to the full philosophical concept. Whitehead halts. He cannot surrender the notion that Nature in its existence is self-contained, that it stands for a reality which in the last analysis is closed to mind. Is this concept of a reality closed to mind a necessity of mathematical and physical science? Some philosophers would agree with Whitehead in saying, Yes. They are the new realists, and are here criticised from that point of view. On the other hand, Einstein and Eddington seem very definitely to say, No, and to be able to prove it. Lord Haldane suggests that Whitehead's own persistent question, in regard to any and every specified point-event —the question, Whose space-time? or, What space-time system?—in its implications is the negation of his own conclusion. This brings out Lord Haldane's foundational fact. Knowledge is a universal within which all distinctions fall. It is not, and cannot be, conceived as an abstract relation between two self-subsistent and existentially exclusive realities, mind and Nature.

Let us now turn to another question, which is equally pressing as a scientific problem, and equally significant as a philosophical problem—the quantum theory. Lord Haldane makes only a brief reference to it (p. 106), but it is in a certain sense even more relevant to the concept which it is his main purpose to expound, the concept of degrees of reality, than the principle of relativity itself. For the quantum theory shows that in scientific explanation, however far we are able to pursue it, we are brought up finally against a fact which positively forces us to appeal to a character of knowledge in plain contradiction of our scientific principle of explanation.

On p. 114 there is a delightful account of the curious statue erected to Gauss and Weber in Göttingen. It is made the occasion of expounding the work of those mathematicians who, as Lord Haldane says, "nearly three-quarters of a century since, prepared the way for thinkers like Einstein and the interpreters of the doctrine of quantitative relativity." But it is also curious to remember that at the same time there was living in Leipzig another Weber, the philosopher and psychologist who has given his name to the famous law of

psycho-physics. Weber's law was the first definite discovery of the fact on which the quantum theory rests. He discovered that in sensible experience changes are not continuous—that is, do not correspond to the continuity of the changes of the physical stimulus, but occur in discrete quanta. He was a parallelist, and thought that changes in the physical environment were concomitant with changes in sensation. He never suspected, probably would have found it difficult to conceive, that changes in the physical world are discrete. Planck's quantum theory is the discovery that the same fact which Weber found to characterise the psychical world characterises the physical world; that energy is emitted, not continuously, but in discrete quanta; that, as Lord Haldane says, we may even have to regard space as a discrete manifold. This comparison is not a fanciful notion, nor purely imaginary. The whole problem was discussed by Henri Poincaré in "Science et Hypothèse" before Planck's discovery. Poincaré cites Weber's law as actual proof that the concept of mathematical continuity is only a postulate, declares that it is unverifiable, and suggests that it may be disproved or superseded. This is peculiarly significant in regard to Lord Haldane's concept of the concrete universal, the concept that reality is relative to the character of knowledge.

The practical gain in such a concept when we are dealing with biology and with the mental sciences is the topic of chap. vi. of the book. The most striking thing about the new scientific revolution is the havoc it is making of the once unchallengeable and universally accepted notions at the basis of the purely mathematical sciences. It is not, for example, Newton's law of inertia, primarily and mainly based on empirical observation, which is suspect. It is the much more fundamental law, the law of the equivalence of action and reaction, a purely rational principle, which seems now to be on its trial. The whole direction of scientific speculation in the nineteenth century was towards the conscious goal of mechanical interpretation. Scientific advance was practically identified with the confident anticipation that all the biological and mental sciences, even including such purely human interests as art and religion, would be mechanistically explained. The new spirit and the new direction in scientific speculation at least recognise that the abstract can never comprehend the concrete; and this recognition more than anything else is bringing about the *rapprochement* between science and philosophy, so long and so unreasonably estranged.

H. Wildon Carr.

A New Book on Cactaceæ.

The Cactaceae. By N. L. Britton and J. N. Rose. Vol. ii. (Publication No. 248.) Pp. vii+239+40 plates. (Washington: The Carnegie Institution of Washington, 1920.)

All cultivators of cacti and all botanists who are interested in this remarkable family of plants will feel satisfaction in knowing that at last we have in the English language a standard up-to-date monograph of the natural order Cactaceæ, which is universally recognised as being the most difficult of all flowering plants to study. With the exception of a few scattered but excellent papers upon them by Drs. Britton and Rose, Dr. Engelman, and Berger, this is the first work in the English language that gives a complete account of the order as we know it to-day. This fine book is so excellently planned and so fully illustrated as to be a long way in advance of the very unsatisfactory German works that have hitherto held the field, and will be found to be a real boon to all who study these plants.

From the introduction to the first volume (a notice of which was published in Nature for September 11, 1919) we learn that Drs. Britton and Rose at first intended to monograph only the Cactaceæ of North America, but, happily, upon a proposal made by Dr. D. T. MacDugal, the plan was extended to include the whole of the family. Extensive preparations were made and a large army of workers was enlisted to collect and photograph the species in their native habitats, the result being that the authors have had at their disposal a larger amount of living and other material, accompanied by field-notes, drawings, etc., than any other students of this group have ever been able to obtain. As the types (when existing) of the older as well as of modern species have also been consulted, the authors have been able to detect and correct many errors of determination that are found in existing monographs.

Vol. ii. is of quarto size, well printed and profusely illustrated with photographs, drawings, and coloured plates, which, it is a pleasure to note, are nearly all originals. There are good keys to the tribes, subtribes, genera, and species, so that, taking into account the aid afforded by the figures, there should be no great difficulty in naming cultivated specimens when in flower.

Each tribe, subtribe, and genus is separately characterised, and the type of each genus indicated. Under each species the synonyms, with the date of their publication, a description, men-

tion of the type locality, the general distribution, references to illustrations, and general notes are given. All the descriptions are in English, and written in a correct but very simplified style, so that anyone can easily understand them. Latin descriptions find no place in this admirable work, which is designed to be useful to the multitude rather than to the botanist alone.

In the first volume the Cactaceæ are divided into the three tribes Pereskieæ, Opuntieæ, and Cereæ. The tribe Pereskieæ contains only the single genus Pereskia, of which nineteen species are described. The Opuntieæ are divided into seven genera, of which Opuntia is the largest, containing 240 species; the other genera have only one or a few species in each. These two tribes fill the first volume, and the Cereæ, which comprise the bulk of the order, are being dealt with in the remaining volumes. The first portion of the Cereæ is accounted for in the present volume, where the plants that are commonly known by the generic title of Cereus are described and illustrated.

It has long been recognised that different species of Cereus produced different types of flower, and since, in other natural orders, differences in floral structure are recognised as being of generic value, some botanists have founded genera upon some of the different floral types found among Cerei. These genera have not hitherto found much favour among botanists or horticulturists, because the plants, when not in flower, often present a great similarity to one another. The authors of "The Cactaceæ," however, have accepted the view that a difference in floral characters should constitute a generic distinction; they have had this view constantly in mind, and carried it to a logical conclusion, so that they have divided the old genus Cereus into no fewer than forty-seven genera, containing 275 species. Twenty of the genera are proposed for the first time in this volume. Whilst there can be little doubt that the plants which have been placed in the genera Heliocereus, Aporocactus, Cleistocactus, etc., should be separated from Cereus, it may be questioned whether those placed in the genera Dendrocereus, Harrisia, Acanthocereus, etc., should be held to constitute more than sectional groups under Cereus. This, however, is a matter of opinion, and time alone will show if the numerous genera maintained in this work will be generally accepted. Whether they are accepted or not, their adoption in "The Cactaceæ" in no way invalidates the usefulness of that splendid work. The reviewer has had considerable experience in the use of existing monographs, and has found "The Cactaceæ" very far in advance of them; it can be recommended with confidence to students.

The only noticeable fault in the work is the rather serious one that exceptions are always neglected in the keys. This, however, is a fault appertaining to most botanical works, and invariably leads the novice astray. For example, should a novice desire to find out, by means of the key given on p. 1 of vol. ii., the subtribe in which the authors place the globose, spineless plant cultivated under the name *Echinocactus* (and *Anhalonium*) *Williamsii*, no place for it will be found. The only spineless plants mentioned in that key belong to the subtribe Epiphyllanæ, which have flat, many-jointed stems. This fault is so easily remedied by including exceptions and variable characters again and again under the headings of different parts of the key that perhaps the authors will endeavour to correct this defect in the continuation of their work. They are to be congratulated heartily upon the manner in which they have so far carried out their very difficult task of evolving order out of the very confused synonymy found in other works upon this group of plants.

N. E. BROWN.

A Study in Geo-chemistry.

The Enrichment of Ore Deposits. By W. H. Emmons. (Bulletin 625. United States Geological Survey: Department of the Interior.) Pp. 530. (Washington: Government Printing Office, 1917.)

UNDER the above modest guise the United States Geological Survey has published a volume of the greatest value to the student of ore deposition, which may fairly claim to rank as one of the most interesting of recent contributions to this very difficult branch of economic geology. The author points out that two phases in the formation of economically important ore deposits require independent investigation, namely, the formation of the primary ore deposits and the subsequent modifications which the more superficial portions in many cases undergo.

The present work is devoted exclusively to a comprehensive investigation of the second of these phases, the genesis of the primary ore deposits being considered indirectly only. The author reviews successively the conditions that make for enrichment, such as amount of rainfall, surface contours, permeability of the rocks, the nature of the underground circulation of water, and in particular the oxidation of sulphide deposits. He lays very great stress upon the last-named, and ascribes the solution of the various minerals

affected almost exclusively to the action of sulphuric acid produced by the oxidation of sulphuretted ores. This thesis is developed in detail in a series of chapters devoted to the chemistry of enrichment, in which the conditions of solution and precipitation, so far as the more important metals are concerned, are worked out in full detail. This section is an admirable contribution to geochemistry, and will well repay careful study. It is perhaps possible that the author pins his faith somewhat too exclusively to the action of sulphuric acid and somewhat underrates the possible effect of other solvents. In part this may be due to the fact that he has confined his studies to the North American continent and to the chemical changes that characterise the temperate zones; thus it is significant that the word "lateritisation" is not even once mentioned, and that this phenomenon, which has played an important part in the secondary modification of certain ore deposits in tropical and sub-tropical regions, is here quite disregarded.

Each of the more important metals is then considered in detail; the principal ores of each, their solubilities and mode of occurrence, are discussed, and the influence of enrichment is illustrated by descriptions of a number of representative deposits of each metal; finally, the non-metallic or gangue minerals are treated in the same way. It will be obvious, even from this brief sketch, that the author has done his work with great thoroughness, and it is easy to foresee that this volume will remain for a long time the standard text-book (for such it really is) on the subject.

It need scarcely be said that there are a number of highly contentious points upon which it would be hopeless to expect any general agreement amongst geologists. Perhaps the phrase to which most will take exception is a statement on p. 15: "Many of the rich deposits of gold are primary." It is not too much to say that the exact opposite of this will be more in accord with the experience of most students of the subject, and that the statement, "*None* of the rich deposits of gold are primary," would meet with far more general acceptance. A gold deposit that has not undergone secondary enrichment is quite exceptional, and many examples where such enrichment has assumed a scale of great importance are familiar to all economic geologists, *e.g.* the Witwatersrand and in Western Australia.

Far more difficult and more debatable is the question whether the author has drawn rightly the line of demarcation between the phenomena that ought and those that ought not to be included in the list of secondary enrichment. There are numerous cases where material too poor to be economically workable (which the author, following Ransome, designates as "protore") has been enriched until it is worth working and thus becomes a true ore. Few will object to the inclusion amongst cases of secondary enrichment of those protores that have been converted into ores by the addition of valuable mineral matter, as, for example, the monzonite copper ores of Bingham, Utah, Ely, Nevada, etc.; it is, however, far more doubtful whether the term can fairly be applied to deposits which have been enriched by the leaching out or dissolving away of gangue material. Thus the important deposits of brown hæmatite of Santander, Spain, have been derived from ferriferous dolomite, containing only some 3 per cent. of iron, by the solution of the carbonates of lime and magnesia. It would probably be more correct to designate these as primary deposits than to look upon them as enriched protore. Many writers classify them as "residual deposits." Obviously, if Mr. Emmons carried his method to its logical conclusion, he would include also clastic deposits, seeing that these are the result of the concentration or mechanical enrichment of mineral deposits that will in many cases have been protores.

It is interesting to note that the author has confined his attention to secondary enrichment, and makes no specific reference to secondary impoverishment as such; necessarily he discusses the phenomenon as antecedent to enrichment, but there are certain cases in which the subject deserves attention for its own sake.

Perhaps reference to such controversial points as the above will serve better than anything else to bring out the difficulties of the subject that Mr. Emmons has so ably dealt with in this volume, and both he and the United States Geological Survey are to be congratulated upon this important contribution to the study of the phenomena of ore deposition.

H. Louis.

Our Bookshelf.

The Elements of Theoretical and Descriptive Astronomy. By C. J. White. Eighth edition, revised by P. P. Blackburn. Pp. xi + 309 + ix plates. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1920.) 17s. 6d. net.

This book is something of a curiosity, if only because it has reached an eighth edition. The first edition was published in 1869 for the benefit of the students of the U.S. Naval Academy. It was an elementary primer giving the simple geometrical facts of astronomy. So far as can be

judged from its latest successor, the work was done neither better nor worse than usual. That the original author's effort has proved more enduring than Bismarck's may be accounted for by its privileged sale in a particular institution.

Had the book been confined to the permanent geometrical elements, and, after the introduction of more modern numerical data and the excision of all archaic matter, offered for sale at one-third of the price, it might have been worthy of attention. The new editor claims to "have endeavored to bring it up to date." The following quotation, giving the latest information on radial velocities, will afford a measure of the reviser's success:—"Mr. Huggins, using a spectroscope of large dispersive power, and carefully comparing the spectrum of Sirius with that of hydrogen, found that the line F in the spectrum of Sirius *was displaced*, by about 1/250th of an inch."

This from America in 1920! To a very fair account of the disappearance of Saturn's rings is appended the remark: "The last disappearance took place in 1907; the next will take place in 1922." Perhaps, on the whole, it is well that the price of the volume should be prohibitive.

Radioaktivität und die neueste Entwicklung der Lehre von den chemischen Elementen. By Prof. K. Fajans. Dritte Auflage. (Sammlung Vieweg: Tagesfragen aus den Gebieten der Naturwissenschaften und der Technik. Heft 45.) Pp. viii+124. (Braunschweig: Friedr. Vieweg und Sohn, 1921.) 6.50 marks.

In this book Prof. Fajans gives a simple and clear account of the advances in chemical theory which have resulted from the study of radio-activity. A brief description of the radio-active bodies and their transformations is followed by an account of their chemical properties, leading to their classification in the periodic system, and the recognition of the existence of elements which, though differing in atomic weight, are identical in chemical behaviour. The author shows how Moseley arrived at a number which is a more fundamental characteristic of an element than its atomic weight, and, developing the Rutherford theory of atomic structure, identifies the Moseley number with the value of the charge on the nucleus of the atom. He is then able to give an explanation of the nature of isotopes and of the periodic classification. A description of Aston's mass spectrograph for the investigation of the isotopes of ordinary elements is given in an appendix.

The book is, on the whole, well written, and the matter has been carefully limited to the essential facts and their explanation on the nuclear theory. Full references are given to the original papers.

Relativitätstheorie und Erkenntnis Apriori. By H. Reichenbach. Pp. v+110. (Berlin: Julius Springer, 1920.) 14 marks.

The author states that the theory of relativity contradicts the critical philosophy of Kant, in reference both to the concept of time and to the relation of physical fact to Euclidean geometry. There are only two possibilities, he says: either the relativity theory is false, or the philosophy of Kant needs amending at the points at which it is in contradiction with Einstein. The first possibility seems ruled out after the brilliant success of the relativity theory, both in its double confirmation in experience and in its theoretical contribution to physical thought. Accordingly, the author sets out to analyse the exact point at which it is at variance with critical philosophy, and finally claims to carry through such a modification of the concept "a priori" that the conflict is resolved. His conclusion is: "We can no longer maintain that the idea of 'a priori' is independent of all experience, but we must hold that 'a priori' principles alone constitute the world of experience." This book will repay reading by those who are specially interested in the philosophical aspects of the relativity theory.

Les Etoiles Simples. By Dr. F. Henroteau. (Encyclopédie Scientifique: Bibliothèque d'Astronomie et de Physique Céleste.) Pp. xi+244. (Paris: Octave Doin, 1921.) 10 francs.

As a guide and index to the great advance in knowledge of the stellar system that has taken place in the last thirty years, this volume will be found extremely useful. Commencing with constellations and star-catalogues, the author proceeds to spectral types and schemes of evolution, notably the giant and dwarf hypothesis that holds the field at present.

The chapter on photometry contains a full description of the photo-electric cell, with instructions for its manufacture. Colour-indices are defined, and systems of colorimetry, both visual and photographic, are explained.

The great increase in the accuracy of stellar parallax determination due to the photographic method, with various refinements suggested by experience, is described in sufficient detail; indirect methods—the spectroscopic of Adams, the moving-cluster method of Boss and others, and the hypothetical-mass method applicable to binaries—are then explained. The remaining chapters deal with proper motions, radial velocities, and stellar distribution.

The book is wonderfully complete considering its small size. Each chapter is followed by a useful bibliography, which will enable students interested in special branches of the subject to carry their researches further.

A. C. D. Crommelin.

Psyche's Lamp: A Revaluation of Psychological Principles as Foundation of All Thought. By Robert Briffault. Pp. 240. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Co., 1921.) 12*s.* 6*d.* net.

There is no doubt excellent matter in this book, but the author's method and dogmatic manner are likely to be very irritating to the inquiring student. As the title indicates, the appeal is rhetorical rather than scientific or logical.

Letters to the Editor.

Pathogenic Organisms in the Pollen of Flowers and Disease in Bees.

THE observations of Dr. Rennie and his co-workers have established an association between Acarine infection and Isle of Wight disease in bees. There still remains, however, the question of the part played by bacillary infection in this and other diseases which affect bees. In this communication I desire to direct attention to two aspects only of this complex problem.

(1) In the course of an inquiry during the last three years into an epidemic having many of the features of the so-called Isle of Wight disease, which has caused the loss of a number of my own hives and other stocks in the Midland area, an aerobic short spore-bearing and gram-negative bacillus resembling *B. pestif. apis,* as described by Dr. Malden in the *Journal of Agriculture,* vol. xv., No. 11, February, 1909, was obtained in large numbers from the fæces of affected bees from all the diseased stocks, and was readily grown, sometimes in pure culture, in broth, or on agar or serum agar.

In 1919 I also found that the same organism could be cultured from the sealed cells of the honey-combs from infected hives. A number of cells were opened by removing the cap with a sterilised instrument, and platinum loops of honey taken from these sealed cells were added to broth or smeared on an agar or serum agar slope and incubated at 37° C. for 36 hours. Numerous colonies of the spore-bearing, gram-negative bacillus were obtained from many of the cells. The organism seems to exist in the honey in the spore form only, no bacillary forms being detected before culture, and no cloudiness or discoloration of the honey being produced. In two cases it grew readily when obtained from infected honey cells which had remained sealed for more than twelve months.

The colonies grown from honey resemble those obtained by culture from the fæces of affected bees. They are smooth and white when small, but soon show a corrugated brain-like surface, and may become slightly yellow or pinkish at a later stage.

The fact that, as Dr. Malden showed, the same organism can be obtained from the intestinal contents of apparently healthy bees is important, and I have also grown it from sealed honey cells from apparently healthy hives. Under these conditions the colonies are generally much fewer in number.

This fact is of interest as bearing on the question of bacillary infection in bees, and also on the problem of the inhibitory effect of honey as a culture medium on the growth of organisms, and their persistence in the spore form.

The same organism has also been cultured on the same media from the compressed pollen removed from the thighs of the honey-bee and from several species of humble bee, and also in one case from honey taken from the nest of *Bombus lapidarius.*

(2) The second point has reference to the life-history of the organism outside the body of the bee and the honey cell.

In 1919 I commenced to investigate pollen from various kinds of flowers frequented and avoided by bees, and in the case of frequented flowers both before and after the opening of the flower.

It is impossible here to describe in detail the large number of experiments carried out on different kinds of flowers. Speaking generally, the spore-bearing, gram-negative bacillus described above, together with other bacillary, and in some cases coccal, forms, were frequently grown from the pollen of flowers frequented by the honey-bee, various species of wild bee, and some other insects, while colonies were absent or were sparsely grown from unopened flowers and from flowers such as the edible and sweet pea and others which are not visited by bees to the same extent. Pollen from the pine and other wind-fertilised trees gave very few colonies. From the pollen at the bottom of the spathe of an arum (*Arum maculatum*), in which numerous flies were imprisoned, a small coccus grew freely, in addition to the bacillus form.

There can be no doubt that the anthers and pistils of flowers visited by bees and other insects provide the chief sites of implantation and dispersal grounds for organisms which pass a portion of their life-history in the alimentary canal of bees and in stored honey.

Further investigation is necessary to decide what effect, if any, exposure to atmospheric conditions and to pollen and to plant secretions exercise on the growth of these organisms.

It seems probable that many kinds of flowers, especially open flowers, frequented by bees and other insects harbour enormous numbers of organisms, some of which at any rate are pathogenic to bees under certain conditions, and that a further study of the bacterial flora of flowers would shed light on the diseases of bees and other insects, and possibly on some diseases which affect animals and even man.

C. J. BOND.

The Nature of the Electrical Conductivity of Glass.

IN the course of some work on the electrical conductivity of some dielectrics, which was recently described before the Royal Dublin Society and forms the subject of a forthcoming paper in the *Philosophical Magazine,* the question arose as to the possible electrolytic nature of the current in the case of materials such as glass. The following simple experiment, which is, I think, new, seems worthy of record as affording evidence against this view.

A thin glass bulb about 1·8 cm. in diameter was blown at the end of a piece of tubing, the whole being then filled with a dilute neutral solution of calcium chloride containing a little phenolphthalein. The bulb was immersed in a small beaker of tap-water placed on an insulating stand. Electrodes were placed in the upper part of the tube and in the beaker, one being connected to a source maintained at about −8000 volts with the aid of rectifying valves, and the other to earth through a sensitive galvanometer. Thus a known current could be passed through the glass wall of the bulb in either direction. Currents leaking along the exterior surface of the glass tube were prevented from passing through the galvanometer by an earthed strip of tinfoil gummed round the tube as a guard ring.

The bulb and tube were filled the day before the test was made, and in the interval a slight pink colour had developed, indicating the solution of a little alkali from the glass. The central electrode was first used as anode, so that the glass of the bulb acted as cathode to the solution. If the bulb conducts like a metal, we should expect a red colour to develop on its surface owing to electrolysis of the solution. If, however, the current through the glass

is purely electrolytic, we should expect the alkalinity to be neutralised by the acid radicle ions driven into solution from the glass. The initial current was 8·5 micro-amperes, rising at the end of fifteen minutes to 13 micro-amperes. By this time the solution in contact with the thinner parts of the bulb was a deep pink. The current was then reversed, the initial value being now 16 micro-amperes. After six minutes the solution in contact with the glass was very nearly, if not quite, colourless. If the current in the glass were electrolytic, there can be little doubt that sodium ions would have been driven into solution, thus maintaining the pink colour. The large changes in the conduction current with time and reversal of direction are probably attributable to alteration and polarisation effects in the glass. The thin parts of the bulb carrying most of the current probably represented an area of only 2 or 3 sq. cm., so that the current density was comparatively large, and the potential gradient probably between 1 and 2 megavolts per cm. The evidence of the colour changes, which were repeated several times, is strongly in favour of the view that under such gradients and at air temperature the conduction current is largely, if not entirely, of a non-electrolytic nature.

HORACE H. POOLE.

Royal Dublin Society, June 20.

The Displacement of Spectral Lines by a Gravitational Field.

ACCORDING to the theory of relativity the paths of moving particles or light pulses are geodesics in a four-dimensional Riemann space defined by the metric

$$ds^2=g_{\mu\nu}dx_\mu dx_\nu.$$

The resulting abstract kinematics is brought into relationship with the facts of experience by the identification of the Gaussian co-ordinates x with the observer's space-time co-ordinates in a Newtonian-Euclidean system. Since the spaces are Euclidean, and since the velocity of light is the same for each observer, it follows that the systems of two different observers are similar, but not necessarily on the same scale.

Consider the field of a single gravitating centre. The metric is given by

$$ds^2=-\gamma^{-1}dr^2-r^2[d\theta^2+\sin^2\theta d\phi^2]+\gamma dt^2.$$

Taking the unit of ds as the fundamental unit, and measuring radial and transverse lengths and times at two different points of the Riemann space, we see that throughout the space the local scale is constant for transverse lengths, varies as $\gamma^{\frac{1}{2}}$ for radial lengths and as $\gamma^{-\frac{1}{2}}$ for times. Since the separated space-time systems of different observers are to be similar, it is clear that their scales cannot be obtained by carrying over the scales of the Riemann space at the observers' world-points. Assume that the observer's time-scale bears to the time-scale at his world-point in the Riemann space the ratio $1:f(r)$. The scales of the Euclidean systems of two different observers then vary inversely as $\gamma^{\frac{1}{2}}f(r)$.

This variation of scale has no effect on the mercury problem or on the deflection of a beam, but it is of fundamental importance in the third crucial phenomenon, the displacement of the spectral lines.

The usual argument shows that

$$\gamma^{\frac{1}{2}}_S dt_S=\gamma^{\frac{1}{2}}_E dt_E,$$

where dt_S, dt_E are measured in the units of the Riemann space. If we transfer to the Euclidean spaces of local observers, the equation becomes

$$\gamma^{\frac{1}{2}}_S f_S dt_S=\gamma^{\frac{1}{2}}_E f_E dt_E.$$

Eddington's argument on p. 129 of "Space, Time, and Gravitation" shows that the time-period *as measured in the units of any one observer* is transmitted by the radiation. Hence dt_S can be compared with dt_E by observation. The measurement of the displacement of the spectral lines determines the function f.

No displacement is to be expected if $f=\gamma^{-\frac{1}{2}}$. In this case, if dt is a time-interval in the Riemann space, $\gamma^{\frac{1}{2}}dt$ is the corresponding observer's interval, and $\gamma^{\frac{1}{2}}dt$ or ds is propagated by the radiation as suggested in my letter of March 10.

The Measurement of Single and Successive Short Time-Intervals.

THE following modification of the well-known method of determining small time-intervals by the discharge of an electrical condenser does not appear to be generally used, judging from some inquiries I have had. Though the modification possibly has been published somewhere—the man who can claim originality in these days is fortunate—this letter may be a help to some other workers.

The well-known method to which I refer consists in so arranging the circuit with a condenser and ballistic galvanometer that the former is charged or discharged during the interval. The potential of the condenser is measured before and as soon after the interval as possible by the galvanometer, and the duration of the interval is proportional to the difference of the logarithms of these quantities.

The modification I first used during 1915 in connection with the measurement of the velocity of detonation of explosives consists in connecting one side of the condenser to the string of a Laby string electrometer. The displacement of the string is proportional to the potential of the condenser, so that during an experiment the string falls from one position to another, and the logarithm of the ratio of these displacements from the zero position is proportional to the time. The accuracy of the method can be increased by using a moving plate and photographing the string's position; it can be increased up to the limit imposed by the accuracy within which the condenser capacity and discharging resistance are known by measuring the displacements on the plate with a microscope.

The advantages of this method as compared with the ballistic method are: (a) the procedure and circuit are much simplified, (b) small leakage is of no importance or embarrassment, (c) the whole process being self-recording, the result is available for measurement at any time, and, further, the inertia of the string or its natural period of vibration does not affect the result.

Its disadvantage in common with the ballistic method is the disturbing influence of the inductance of the circuit upon the rate of flow. It may be possible in some applications to calculate this, or to allow for it by calibration.

If a bicycle ball suspended by a long thin wire be allowed to impinge against, and rebound from, the vertical face of an anvil until it comes to rest, the resulting record with its gradually diminishing steps, corresponding to the several durations of contact, affords a pretty example of the application of this method to the measurement of rapidly successive short time-intervals.

ALAN POLLARD.

The Imperial College of Science and Technology, South Kensington, S.W.7, June 14.

Sex-change in the Native Oyster (O. edulis).

It is well known that sex-change in the native oyster (*O. edulis*) occurs at some period of its life. This mollusc apparently always begins life as a male, and may change into a female at the age of one or two years. Very little is, however, known about the change of sex afterwards. In following up the indications given from a general study of breeding (see J. H. Orton, "Sea-temperature, Breeding, and Distribution in Marine Animals," Journal of the Marine Biological Association, vol. xii., July, 1920, pp. 339–66), it seemed certain that an oyster ought to continue breeding in the same season even after becoming white-sick, *i.e.* after extrusion of ova into the mantle cavity. Thus if a breeding oyster were marked and examined afterwards, it should be possible to find out something about a possible *annual* change of sex. Accordingly on July 30, 1920, two white-sick oysters were isolated in a tank at Plymouth, and one of them was cut open and examined on August 26, 1920. At the latter date the one examined[1] was found to have its gonad full of wholly ripe sperm-morulæ, which disintegrated into separate active and apparently ripe sperm as soon as they were placed in sea-water. Thus a female-functioning oyster had changed into a male-functioning oyster within less than a month. An indication of this change had already been given on July 29, when the gonad of a white-sick oyster—examined at the moment when it contained embryos in the mantle cavity—showed developing sperm-morulæ and some actively tailed sperm-morulæ.

The occurrence of developing sperm-morulæ in microscopic sections of "white-sick" or "black-sick" oysters has, indeed, been already observed by P. P. C. Hoek in a practically unknown and very valuable piece of work on the oyster ("Rapport over de Oorzaken van den achteruitgang in hoedanigheid van de Zeeuwsche oester," p. 175. Uitgegenen Door Het Ministerie van Waterstaat, Handel en Nijverheid, 's Gravenhage).

This year the observations on "white-sick" oysters have been repeated, and all the oysters examined have shown either some sperm-morulæ with active tails which disintegrate into separate sperm in sea-water, or developing sperm-morulæ. It is seen, therefore, that even at the time an oyster is carrying its own embryos it is changing into a male-functioning form, which will apparently function as a male within a very short time.

An endeavour is being made this summer to carry out on a larger scale the isolation in the sea of oysters of known sex at a particular moment with the view of determining the sex at a later date. It is hoped in this way to investigate also the possible change of an oyster which is male-functioning at the beginning of the breeding season into a female-functioning form at a later period in the same season.

A New Acoustical Phenomenon.

I HAVE read Dr. Erskine Murray's letter in NATURE of June 16, p. 490, with very great interest, but I think there are two difficulties in the explanation that he has there advanced :—

(1) It is hard to see how or why an aeroplane should emit a series of pairs of double sound impulses; and (2) even if they were emitted, the ear would find it difficult to observe any change in pitch as the distance from the ground was varied; for it is found by experiment that pairs of sound impulses cause a sensation of pitch which is sufficient for the identification of a note as being high or low, but is too indefinite for the appreciation of small differences of wave-length.

I should like to suggest instead that the phenomena observed by Dr. Erskine Murray are due to the presence of a series of stationary sound-waves of various wave-lengths lying parallel to the ground, analogous to the stationary waves of light employed in Lippmann's colour photography. These stationary sound-waves would be produced by reflection at the surface of the ground, the nodes occurring at a distance from the ground inversely proportional to the pitch.

This suggestion fits in with the observed facts (1) that the note heard varies inversely as the height of the observer's ear from the ground; (2) that the effects are best observed when the aeroplane is nearly overhead; (3) that the note heard at a given height varies with the angle of elevation of the aeroplane; and (4) that the surface of the ground must be smooth.

As to the source of these series of notes of different wave-length, it would seem that the turbulent air behind wings, framework, and propeller must be responsible, and the fact that wind passing through a tree can create similar phenomena would seem to confirm this view. With regard to the physiological aspect, it has long been known that double sound impulses do give a crude sensation of pitch, and both theories of hearing have offered suggestions to account for it.

H. HARTRIDGE.

King's College, Cambridge.

DURING the war and since I have often noticed how the apparent pitch of aeroplane noise changes suddenly as an aeroplane travels over the street in which one is standing. I had put this down to reflection, but not on the lines followed by Dr. Erskine Murray in his letter in NATURE of June 16, p. 490. As the problem is of practical importance to such bodies as the War Office and Admiralty, in, for example, recognising aircraft at night or in fogs, it seems worthy of discussion.

If the sound from an aeroplane were a pure tone no amount of reflection could give the sensation of the octave, for two harmonics of equal period combine into an harmonic of the same period. If the sound is impure and has overtones, combination of direct and reflected waves could have the effect only of altering the quality by suppressing some components and re-inforcing others. I suggest that Dr. Murray heard the upper tones because of interference between the direct and reflected waves of the lower. That the noise from an aeroplane, though often of musical quality, is not a pure tone is clear. Exhaust noise, in spite of the approximately harmonic motion of the pistons and valves, is not a pure tone. Complications arise from the explosive emission of the gases. Moreover, in addition to the dominant exhaust noise, there are secondary noises from propeller, fuselage, etc.

H. S. ROWELL,

Director of Research, The Research Association of British Motor Manufacturers.

15 Bolton Road, Chiswick, W.4, June 20.

THE acoustical phenomenon described by Dr. Erskine Murray in NATURE of June 16, p. 490, is fully discussed by F. A. Schulze in a paper which appeared in the *Annalen der Physik* in 1916 (vol. xlix., p. 683). References to earlier work on the subject are

given in this paper, and it appears that the effect was observed and described by Savart as early as 1839.

W. B. MORTON.

Queen's University, Belfast, June 21.

An Algebraical Identity.

THE values of the coefficients of Y and Z are given in Prof. Mathew's "Theory of Numbers," p. 218, for the primes 3 to 31. I have calculated the values for the primes 37 to 61 by the method given by Prof. Mathews on p. 216 of his book. My result in the case of $p=37$ agrees with that given in NATURE of June 9, p. 456. The other results are as follows, the coefficients being given to the middle term inclusive when that exists, and in the other case to the first of the pair of terms at the middle:—

$p=41$; Y, 2, 1. 11, 16, 14, 29, 30, 22, 36, 34, 20;
Z, 1, 1, 2, 4, 3, 4, 6, 4, 4, 6.

$p=43$; Y, 2, 1, −10, 6, 16, −20, −4, 27, −15, −7, 17;
Z, 1, 0, −2, 2, 2, −4, 1, 3, −3, 1.

$p=47$; Y, 2, 1, −11, −17, −9. 6, 29, 37, 20,
Z, 1, 1, −1, −3, −4, −3, 1, 4,
−2, −16, −11;
4, 2, −1.

$p=53$; Y, 2, 1, 14, −6, 8, −14, −4, 19, −12,
Z, 1, 0, 2, −2, 0, 0, −1, 4,
24, −9, −11, 27, −25;
−2, 1, 1, −3, 5.

$p=59$; Y, 2, 1, −14, 8, 7, −35, 22, 12, −33,
Z, 1, 0, −2, 3, −1, −4, 4, −1,
18, 23, −29, 14, 18, −29;
−4, 3, 1, −4, 4, −1.

$p=61$; Y, 2, 1, 16, −7, 32, −20, 63, −33, 72,
Z, 1, 0, 3, −2, 6, −3, 9, −6,
−54, 89, −62, 88, −89, 95, −81;
10, −7, 12, −10, 11, −11, 13.

The first case where Legendre's rule fails is $p=41$.

H. C. POCKLINGTON.

5 Well Close Place, Leeds, June 12.

THE result for $p=37$ given in NATURE of June 9, p. 456, was found to conform to Legendre's rule; since this rule fails in the case of $p=61$, it is interesting, as noted by Prof. Mathews, to know if this is the lowest prime for which the rule fails.

I have worked out the case for $p=41$, and find the expression of the 20th degree in x for Y to have the following coefficients:—

$$2+1+11+16+14-12-11-19-5-7+20-7-5$$
$$-19-11-12+14+16+11+1+2.$$

And since X is of the 40th degree in x, each coefficient being $+1$, I find $(Y^2-4X)/41$ of the 38th degree in x with the following coefficients:—

$$1+2+5+8+12+2-12-28-20-14+15+18+19$$
$$-24-23-36+9+28+72+28+9-36-23-24+19$$
$$+18+15-14-20-28-12+2+12+8+5+2+1.$$

Putting $x=1$, the sum of these coefficients equals -4, hence $(Y^2-4X)/41$ cannot be a square, so that the rule fails, 41 being the lowest prime for failure.

J. CULLEN, S.J.

Stonyhurst College, June 17.

Artefacts and their Geological Age.

IN NATURE of June 9, p. 458, Mr. J. Reid Moir describes some flint implements found *embedded in the surface* of the ferruginous "pan" at the base of the cliff near Sheringham, and he bases certain conclusions upon this find. From his description of the occurrence of the flints it seems clear that in this case they may not be of the same age as the "pan," in the upper surface of which they were found embedded. A little while ago, on the beach at Flamborough, a small deposit of ferruginous conglomerate was found, in which there was embedded a typical Neolithic "scraper," as well as several pebbles, and the conglomerate proved to be formed upon a horseshoe. But no one here assumed that the horseshoe was Neolithic in date, or that the scraper was made during the past fifty years. More recently, on an excursion to South Ferriby, on the Humber shore, firmly embedded in a ferruginous "pan," immediately at the base of a cliff of Boulder Clay, was a trouser button. It had to be extracted with a hammer. But no Yorkshire geologist is likely to write to NATURE to try to prove that pre-Glacial man in the Humber district wore trousers.

T. SHEPPARD.

The Municipal Museum, Hull, June 27.

Iron Currency-Bars.

IN NATURE of May 19, p. 372, reference is made to iron currency-bars and "early British water-clocks." The discovery of the true nature of the currency-bars is not, as is implied, a recent one, but was made in 1905 by Mr. Reginald Smith (see his paper, Proceedings of the Society of Antiquaries, vol. xx., pp. 179–94). Similarly, the "early British water-clocks" were first authoritatively dealt with by Mr. Smith in 1907 (see his paper, *ibid.*, vol. xxi., pp. 319 *sqq.*). I understand that Dr. Newton Friend made this quite clear in the paper referred to, and gave his references.

It may be of interest to add that a hoard of currency-bars has recently been found near Winchester, and that the site is now being excavated by a band of volunteers under the direction of Mr. R. W. Hooley, hon. curator of the Winchester Museum. The currency-bars were exhibited at a recent meeting of the Society of Antiquaries.

June 20.

O. G. S. CRAWFORD.

History of the Churn.

IN No. 23 of the *Agricultural Ledger*, issued by the Government of India, and published in July, 1895, there is a *précis* of official correspondence on the Indian churn which begins: "In a letter addressed to the Government of India, Herr B. Martiny, of Berlin, asked for information regarding the Indian Churn. He there announces that he is engaged writing a history of the Churn, and is desirous of obtaining certain particulars regarding 'the old Indian Churn,' of which he furnished a drawing." Has this "History of the Churn" been published in book form, or in the journal or transactions of any society? May I ask readers of NATURE if they can afford any information on the subject? If Herr Martiny addressed similar communications about native or ancient forms of churns to European, American, and Far Eastern Governments, and had his inquiry as fully replied to as it was by the Government of India, there must be pigeon-holed somewhere a mass of interesting data.

R. HEDGER WALLACE.

Cosmogony and Stellar Evolution.[1]

By J. H. JEANS, SEC.R.S.

II.

The Evolution of Stellar and Planetary Systems.

IN the last lecture we followed up, so far as is permitted by modern theoretical and observational research, the train of ideas on which Laplace had based his nebular hypothesis. Theoretically we found that a shrinking mass of rotating gas ought in time to assume a lenticular shape, after which further shrinkage would result in the ejection of matter from the sharp edge of the lens. It is suggested that the spiral nebulæ form instances of this process, the spiral arms being the ejected matter and the central nucleus the remnant of the original rotating mass of gas. The spiral arms are observed to break up into condensations, a process of which a theoretical explanation can readily be given. But on inserting approximate numerical values it is found that each condensation must have a mass comparable with that of a star. In the spiral nebulæ we are watching, not the birth of planets, which Laplace attempted to explain by his nebular hypothesis, but the birth of the stars themselves. The process is, in its main outlines, identical with that imagined by Laplace, but is on a more stupendous scale.

The separate stars when set free from the parent nebula are themselves shrinking and rotating masses of gas; they may be thought of as small-scale models of the nebula which gave them birth. We naturally inquire whether the process of evolution of these small-scale models will be the same as in the parent nebulæ. The answer is provided by a mere inspection of the physical dimensions of the formulæ which govern the dynamical processes of evolution. It is found that, as regards the central mass of lenticular shape, the small-scale model operates precisely like the bigger mass. Any rotating mass of gas, provided only that it is sufficiently great to hold together under its own gravitation, will in due course assume the lenticular shape and discharge matter from its equator. But as regards the ejected matter, the small-scale model does not work in the same way as the bigger mass. If the matter ejected from a big mass forms a million condensations, the matter yielded from a small mass of one-millionth part of the size will not form a million tiny condensations—it will form only one condensation, and will, moreover, form this one only if other physical conditions are favourable. In actual fact, when regard is had to numerical values, it is found that other physical conditions are not favourable. The matter will be ejected at so slow a rate that each small parcel of gas will simply dissipate into space without any gravitational cohesion at all. Some molecules will probably escape altogether from the gravitational field of the central star, while the remainder will form merely a scattered atmosphere surrounding the star. For this reason, in addition to others, the conception of Laplace does not appear to be capable of providing an explanation of the genesis of planetary systems.

So far we have studied the way in which a mass of gas would break up under increasing rotation. As a matter of theoretical research it is found that a mass of homogeneous incompressible substance, such as water, would break up in an entirely different fashion. It is further found that there are only these two distinctive ways in which a break-up can occur, so that if a mass the rotation of which is continually increasing does not break up in one way it must break up in the other. As a star, from being a mass of gas of very low density, shrinks into a liquid or plastic mass of density perhaps comparable with that of iron, it passes through a critical point at which there is a sudden swing over from one type of break-up to the other. This critical point occurs when the density of the star has become such that the ordinary gas-laws are substantially departed from throughout the greater part of the star's interior. This density is, however, precisely that which marks the demarcation between giant and dwarf stars. Thus the general conclusion of abstract theory is that a giant star will break up under increasing rotation in the way we have already had under consideration, but that a dwarf star will break up in the same way as a homogeneous incompressible mass, such as a mass of water.

The discovery of the method of break-up in this second case forms one of the most difficult problems of applied mathematics. In spite of the labours of many eminent mathematicians, among whom may be mentioned Maclaurin, Jacobi, Kelvin, Poincaré, and G. H. Darwin, the problem is still far from complete solution. It is found that as the rotation of a homogeneous mass increases the boundary remains of exact spheroidal shape until an eccentricity of 0·8127 is reached, at which the axes are in the ratio of about 12 : 12 : 7. With a further increase of rotation the boundary ceases to be a figure of revolution; it becomes ellipsoidal and retains an exact ellipsoidal shape until the axes are in a ratio of about 23 : 10 : 8. Beyond this it is impossible for the mass to rotate in relative equilibrium at all, and dynamical motion of some kind must ensue. At first a furrow forms round the ellipsoid in a cross-section perpendicular to the longest axis, but the cross-section in which the furrow appears does not divide the figure symmetrically into equal halves. The furrow deepens, and at this stage the problem eludes exact mathematical treatment. It appears highly probable, although it cannot be rigorously proved, that the furrow will continue to deepen until it separates the figure into two unequal masses. On the assumption that this is what

[1] Lectures delivered at King's College on May 17 and 24. Continued from p. 560.

would actually happen we may conjecture that the process we have been describing is that of the fission of a single star into a binary of the familiar type, but the conjecture is beset by many difficulties. To mention one only: if we have truly described the history of a star before fission, the star ought during a moderate part of its life to possess an ellipsoidal figure, and as this rotated the light received from the star ought to vary to an extent which just before fission might amount to 0·9 magnitude. Yet I believe there are only three known stars whose variation of light is such as could possibly be accounted for by an ellipsoidal surface, and even in these cases the interpretation is doubtful. On the other hand, very considerable reassurance is provided by the researches of Russell on multiple stars. After a star has broken into two parts by fission both parts will continue to shrink, so that either or both may in turn again break up, and a triple or quadruple system be formed. Russell finds that in a multiple system which has been formed in this way the distance between the stars formed by subsequent fissions cannot be more than a small fraction, at most about one-fifth, of the distance between the pair generated by the original fission. A mere glance at a catalogue of multiple stars will show that this condition is fulfilled by the majority of observed systems. On account of foreshortening the apparent separations will not always appear to conform to the rule, but Russell has shown, as the result of a careful statistical discussion, that the exceptions agree, both in kind and in number, with what might be expected from foreshortening.

We have now traced out the life-history of a rotating and shrinking mass from beginning to end, from its start as a gaseous mass of very low density, through its assumption of a lenticular shape and its first break-up as a spiral nebula, through its subsequent condensation into separate stars, to their final fissions into binary and multiple systems. The picture has been distressingly incomplete, and it cannot be denied that the story is beset by many difficulties and uncertainties. The mathematical investigation is far from perfect; gaps in theory have frequently been bridged by nothing more substantial than conjecture; in many cases there has been room for grave doubt as to the identification of observed formations with those predicted by theory; in one instance at least a formation predicted by theory, the ellipsoidal star, is practically unknown to the observing astronomer. But, after allowing for all imperfections, we have a tolerably complete knowledge, so far as the main outlines are concerned, of the whole chain of configurations which will be assumed in turn by the rotating shrinking mass of Laplace, and on this chain there does not appear to be any room for the solar system.

Apart from this, there are weighty reasons for thinking that our system has not been formed as the result of a rotational break-up. The angular momentum of a system remains constant during a process of breaking up, and, as was pointed out by Babinet in 1861, even if the whole angular momentum of the solar system were now concentrated in the sun it would still have less than a quarter of the angular momentum requisite for breaking up at its present density. Except in the improbable event of the solar system, since fission, having been robbed by a passing star of by far the greater part of its angular momentum, its rotation can never have been sufficient to cause a break-up. Clearly there is a case for examining whether some other agency cannot produce a system such as ours.

The sun and moon, as we know, raise tides on our earth the height of which forms only an inappreciable fraction of the earth's radius. If our earth were replaced by a mass of liquid or gas of low density the fraction would be greater, varying inversely as the density of the mass. If the sun and earth were placed much nearer to one another than now the tides would be increased in the ratio of the inverse cube of their distance apart. We can easily imagine conditions under which the heights of the tides would be comparable with the radius of the earth, and here the simple formulæ which the mathematician uses to calculate the heights of terrestrial tides become useless. The general investigation of the succession of shapes which will be assumed by a gaseous or plastic mass as the tidal forces on it continually increase presents a difficult but not altogether intractable problem for the mathematician.

It is found that the tides will be of the general type with which we are familiar on the earth until a certain critical height of tide is reached. This critical height is comparable with half the radius of the mass, being greater or smaller according as the mass is of more or less uniform density. After this critical height has been passed, there is no longer a configuration of equilibrium under the tidal forces. Dynamical motion ensues, and the general nature of this motion will consist in the ejection of two arms or jets of matter, one towards the attracting mass and one, which may be smaller, or may be absent altogether, in the exactly opposite direction. If the tide-generating forces should be suddenly removed at this stage the jets would, of course, fall back into the mass from which they emerged, and this would in time resume its spherical form. But if the tidal forces persist, the jets will continue to be thrown out, and it can be shown that a continuous distribution of density in these jets would be unstable, just in the same way, and for similar reasons, as in the case we previously discussed of the jets thrown out from a rotating mass of gas. Condensations would form in the jets, and ultimately the jet would break up into separate detached masses.

According to the tidal hypothesis of the origin of the solar system, the sun was at some past time subjected to intense tidal forces from a passing star, the sequence of processes we have just described took place, and the emitted jet broke

into fragments which are our present system of planets. From the mathematical investigation on which this hypothesis is based, it appears that the fragments would each be comparable in mass with the original sun if the matter of the sun had been of approximately uniform density, but would be very small by comparison if the sun had been gaseous with high central condensation. The smallness of the masses of the planets in comparison with that of the sun must, therefore, be taken as indicating that the sun was in a gaseous state with high central condensation when the planets were born. The jets of matter thrown out would also be gaseous, but would rapidly cool in the process of ejection, and might soon liquefy or even solidify. It can be shown that the planets which would be formed out of the middle portion of such a jet ought to be much more massive than those formed near the ends, and this may possibly provide an explanation of the comparatively great masses of Jupiter and Saturn. We imagine that the planets at first described orbits under the combined gravitational action of the sun and the passing star by which the cataclysm was caused, but as this star receded they were left revolving, as at present, around the sun. During their earlier motion they may themselves have been broken up by the tidal action of one or both of the big masses present, and such a process may explain the origin of the satellites of the planets.

Such, in its main outlines, is the tidal theory of the genesis of the solar system. So far as can be seen, a vast amount of further mathematical research is needed before it can be either definitely accepted or finally condemned. For myself, I find it more acceptable than the rotational theory, or any other hypothesis so far offered, of the origin of the solar system. Time does not permit of a discussion of its difficulties, but I may perhaps conclude by stating what seem to me to be its main advantages over the rotational theory.

(i) It escapes the well-known criticism of the rotational theory that the present angular momentum of the solar system is too small to be compatible with a previous rotational break-up, and I do not know of any similar quantitative criticism which can be brought against the tidal theory.

(ii) The solar system is arranged with reference to two planes—the invariable plane of the system, which contains the orbits of the outer planets, and a second plane inclined at about 6° to the former plane, which contains the sun's equator and the orbit of Mercury. A system which had broken up by rotation alone ought to be arranged symmetrically about one plane—the original invariable plane of the system. On the tidal theory the two planes of the solar system are readily explained as being the plane in which the tide-raising star moved past the sun, and the original plane of the sun's rotation.

(iii) Theoretical investigations suggest that there is only one possible end for a rotating system, namely, a binary or multiple star of the type familiar to astronomers, and it is quite certain our system is not of this type. Similar investigations on tidal action suggest that the final end of a system broken up by a tidal cataclysm ought to show many of the features of our present solar system.

The Edinburgh Meeting of the British Association.

By Prof. J. H. Ashworth, F.R.S.

Local Arrangements.

The British Association meeting to be held during the week September 7–14 is the fifth meeting of the Association to be held in Edinburgh, the previous meetings having been in 1834, 1850, 1871, and 1892. The last of these, under the presidency of a distinguished son of Edinburgh—Sir Archibald Geikie—was a memorable and successful meeting, and the citizens of Edinburgh are anxious to make the forthcoming meeting no less notable and successful.

As at the last Edinburgh meeting, the reception room, the headquarters of the Association, and the bureau of information will, by permission of H.M. Office of Works, be the Parliament Hall, in which the Scottish Parliament met until the Treaty of Union in 1707. One of the courts adjacent to the hall will be used for the meetings of council and of other administrative committees, and by permission of the Faculty of Advocates rooms in the advocates' library, which is adjacent to Parliament Hall, have been provided for the use of the president and general officers, and the advocates' writing-room has been placed at the disposal of members. The attention of members is directed to the rule prohibiting smoking in any part of the library and in Parliament Hall; a smoking-room is provided near the reception room. The usual postal (including telegraphic) facilities will be provided in the post office at the entrance to the reception room.

The sectional meetings will be held in the lecture rooms of the University. Six of the sections will meet in the Old College, two in the adjacent departments of natural philosophy and engineering, three sections and the conference of delegates in the University New Buildings (the medical school of the University), and the remaining two in the department of agriculture and forestry, which is within four minutes' walk of the University New Buildings and of the Old College. In connection with several of the sectional meetings, laboratory accommodation will be available for apparatus and specimens which members may desire to exhibit to illustrate their communications to the sections.

Writing-rooms will be provided in the University and in the Unions. The University library in the Old College is to be open so that members may consult books and the principal literary and

scientific journals. The Upper Library contains many objects of literary and scientific interest, including Charles Darwin's class-cards for the lectures which he attended in the University in the years 1825–26, and will be available as a withdrawing-room and additional writing-room. At the Royal Society of Edinburgh, 22 George Street, members may see the principal scientific journals and consult books in the library.

The inaugural meeting and the evening discourses will take place in the Usher Hall, which is an ideal hall for the purpose and has excellent acoustic properties. The hall has spacious corridors, foyers, and cloak-rooms; its interior is well proportioned, and as the grand circle and the gallery above it are constructed on the cantilever principle there are no pillars to obstruct the view of any member of the audience. In this hall also will be given three of the public lectures to citizens. Sir Oliver Lodge will give the opening lecture on "Speech through the Ether, or the Scientific Principles Underlying Wireless Telephony"; Prof. Dendy will lecture on "The Stream of Life"; and Prof. H. J. Fleure on "Countries as Personalities." A special lecture, arranged in collaboration with Section M (Agriculture), for agriculturists will be given in the Natural History Theatre in the Old College of the University on the afternoon of market day (Wednesday, September 7) by Dr. E. J. Russell on "Science and Crop Production."

The Lord Provost, magistrates, and council of the city will give a reception in the Royal Scottish Museum on the Thursday evening; there will be a special graduation ceremonial in the M'Ewan Hall on the Tuesday afternoon, and a garden party immediately afterwards, which the local committee hopes to give in the Zoological Park.

The handbook is not quite on traditional lines; it is not an account of the history, topography, and organisation of the city—this information is accessible elsewhere—but will give an account of the place of Edinburgh in scientific progress. Owing to the present high cost of printing, the book must be kept within the modest limits of about 230 pages, but it is hoped that the authors who are collaborating in its production will be able to give within this compass an adequate account of the main lines in the advancement of science which have been especially associated with Edinburgh.

In order to give members an opportunity of visiting the more important places of historical and general interest round Edinburgh, arrangements are being made for excursions on the Saturday (*a*) to Loch Lomond, the Trossachs, and Stirling, (*b*) to Melrose Abbey and the Scott country, and (*c*) by river to Alloa and Stirling. Shorter excursions have been planned for other days. One of these is to H.M. Dockyard, Rosyth, by kind permission of Admiral Sir Herbert Heath; another is to Dunfermline, where the party will not only be able to inspect the historical abbey and church, but also those interested in sociology will have an opportunity of seeing the work of the Carnegie trustees; and another is to Linlithgow, where, in addition to historical interests, the party will be able to comprehend, from a commanding point of view, the manner in which the Forth valley has been eroded. Other excursions will be arranged to Swanston (the former home of Robert Louis Stevenson) and Craigmillar Castle, and to the Castle and Chapel of Roslin and to Hawthornden. Those interested in the architecture and picture galleries of the noble houses of Scotland will enjoy the excursion to Dalkeith Palace, the residence of the Duke of Buccleuch, and to the Marquis of Lothian's seat at Newbattle Abbey.

Edinburgh itself has not been forgotten in these arrangements; small parties will be conducted over the "Old Town," especially the "Royal Mile" from the Castle to Holyrood, and the member who avails himself of this opportunity will visit, under the guidance of Prof. Baldwin Brown, Dr. John Harrison, and other experts, the scenes of many of the most moving events in Scottish history.

The city and the surrounding country present many features of interest to the geologist, the biologist, the engineer, the geographer, and the student of the growth of cities. Sectional excursions to the chief points have been planned.

It has often been stated that Edinburgh is not an industrial or commercial city, probably because the reputation which it has enjoyed in other respects has overshadowed this aspect of its activities. In point of fact, however, banking, insurance, and financial interests are strongly represented, and the city has important industries. It has long been celebrated for book and map production, and among other industries are brewing and distilling, shipbuilding, engineering, rubber and chemical works. Arrangements have been made for the sections concerned to visit works representative of these industries.

The first list of hotels and lodgings is now ready, and can be obtained either from the London office, or from the Local Secretaries, The University, Edinburgh. Members should bear in mind that September is a busy month for ordinary tourist traffic in Edinburgh, and that they should therefore make their arrangements early. Some accommodation in hostels, at moderate charges, has been placed at the disposal of the local executive committee. Ladies and gentlemen desiring such accommodation should address their applications to the local secretaries direct before the end of July, by which time it is expected that the available places will be allotted. Preference will be given to scientific workers.

Luncheon and tea will be obtainable at moderate charges in the University Union and the University Women's Union, both of which are adjacent to the sectional meeting-rooms. Gentlemen who are members of the Association will be honorary members of the Union for the week, and ladies who are members will be honorary members of the Women's Union. In each case the honorary members will have the usual privileges, and may introduce one or two guests—ladies or gentlemen.

For the convenience of members arriving on Wednesday evening, September 7, who will have only a short time at their disposal between the time of their arrival and the inaugural meeting, arrangements have been made with the station-masters at the Caledonian and Waverley Stations to establish inquiry offices of the Association at which membership tickets will be issued. These offices will be opened at 5.30 p.m. for about an hour and a half, but members who anticipate arriving in Edinburgh after 5 p.m. would do well to obtain their tickets by post beforehand so as to avoid any congestion at these temporary offices.

Annual Visitation of the National Physical Laboratory.

The annual visit to the National Physical Laboratory of the members of the General Board took place on June 28. A large number of guests were present, and were received by Prof. C. S. Sherrington, president of the Royal Society, the chairman of the General Board, and by the director of the laboratory, Sir Joseph Petavel.

An interesting ceremony preceded the visit, when a bas-relief in bronze of the late director, Sir Richard Glazebrook, was presented to the laboratory. The presentation was made by Sir Joseph Thomson, Master of Trinity College, Cambridge, and received on behalf of the laboratory by Prof. Sherrington. The bas-relief is the gift of a large number of friends of the late director, including many past and present members of the General Board.

It is now more than eighteen months since Sir Richard was succeeded by Sir Joseph Petavel, who has carried on very actively the work of his predecessor. Some buildings planned in 1918 are still in process of erection at Teddington, and the work of the laboratory continues to increase in magnitude and importance. The Admiralty has erected a research laboratory within the grounds of the National Physical Laboratory, so that much of its special work may be carried on in close co-operation with it.

As on previous occasions of this kind, the laboratory was thrown open to the visitors, who were given an opportunity of seeing the work that is at present being conducted in the various departments.

A wind tunnel of cross-sectional area 7 ft. by 14 ft. has been completed during the course of the current year, and affords a valuable addition to the equipment of the aerodynamics department. In it a new method for the measurement of rotary derivatives on an aeroplane was demonstrated. Demonstrations in the other tunnels included the measurement of the thrust and torque on an air-screw working in front of a streamline body with the simultaneous measurement of the drag on the body; pressure plotting on an airship hull which was carried out by means of a number of fine steel tubes run longitudinally along the hull in grooves and made flush with wax; and the measurement of lift, drag, and pitching moment on a model aerofoil supported on wires and hung from balances on the roof of the tunnel. Several complete models of aeroplanes were also exhibited.

The engineering department exhibited a machine presented to the laboratory by Mr. C. E. Stromeyer for the rapid determination of the fatigue ranges of materials under reversals of shear-stresses. Forced torsional vibrations are given to the specimen under test by means of a rocking arm and flywheel the mass of which can be adjusted. The specimen acts as an elastic constraint between the rocking arm and the flywheel. The usual method of finding the limiting range of stress by endurance tests requires six specimens, and, with the machine running continuously, occupies a week. By the new method the limiting range of stress can be found on a single specimen by two independent means at the same time, and the total time taken for the test varies from five minutes to a quarter of an hour.

In order to investigate the distribution of the air currents produced by the present system of ventilation in the debating chamber of the House of Commons, a wood model (one-eighth full size) has been constructed. Air is supplied to this through ducts of the existing pattern from a fan, the strength and direction of the air currents being investigated by air-speed meters and smoke bands.

An experimental range has been constructed for the study of the motion of 1-in. projectiles in flight. The range is being fitted to carry this out by a series of "jump" cards, and also photographically by the spark method of Prof. Boys.

Other exhibits in this department were the following: Apparatus for studying the effect of pressure and temperature on the production of detonation in a closed explosion vessel; apparatus by means of which the temperature of the lubricant, the load on the bearing, and the speed of the journal can be varied in order to obtain the coefficient of friction of lubricants under varying conditions; apparatus for determining the distribution of frictional resistance over thin plates; and machines for various tension and compression tests.

A new apparatus for the autographic determination of changes in the electrical resistance of alloys with varying temperatures up to and beyond the melting point was exhibited in the metallurgy department. A Morgan electric melting furnace, in which a clay-lined graphitic crucible acted simultaneously as the metal container and heating element, was shown in operation. Demonstrations were given in the experimental rolling-mill, illustrating the effect on the rolling properties of certain non-ferrous alloys of unsuitable mechanical and thermal treatment prior to the rolling operation.

There were also shown in this department exhibits illustrating the macro-structure of castings in various types of moulds, graphite moulds and ingots cast in them; specimens illustrating the behaviour of pure zinc under tensile tests at various temperatures, and new apparatus for the pressure casting of china clay pots for glass melting.

In the heat division of the physics department two novel forms of optical pyrometer were shown, one a precision laboratory standard, and the other a portable instrument suitable for workshop use. Both were of the disappearing filament type in which an image of the hot object is superimposed on the filament of the pyrometer lamp and the brightness matched by varying the current through the lamp. In the standard instrument two lamps are fitted which can be interchanged exactly in the field by a simple transverse motion, and each lamp is provided with fine adjustment in three mutually perpendicular planes. The portable instrument is a self-contained unit which can be carried in the pocket. The telescope, variable rheostat, and ammeter are integral parts of the instrument, and the ammeter is graduated to read temperatures direct.

A variety of hygrometers was shown, as were also appliances for the rapid calibration of these instruments. Considerable modifications have been made in the dew-point apparatus with the view of arranging it in a form suitable for use under cold storage conditions.

In the radiology division was shown a Bragg X-ray spectrometer for the investigation of the crystal structure of materials. The spectrometer is also designed to measure accurately the absorption of X-rays of definite wave-length in different substances. The whole of the high-tension circuit is enclosed in a box covered with lead, so that the measuring instruments are entirely protected from stray radiation. The apparatus employed to investigate the measurement of the intensity of a beam of X-rays with special reference to the barium platinocyanide pastille was shown, and an improved type of tintometer for comparing the tints of pastilles was also demonstrated.

The optical division showed a new method for determining loss of light in optical instruments such as range-finders, periscopes, etc. An optical pyrometer, adapted for use as a surface brightness photometer, is employed to measure the brightness of a suitable source of light and of its image formed by the optical instrument. Two precision methods of goniometry by substitution were demonstrated. In one of these an accuracy of about $1''$ of angle is readily obtained, and in the other, which is suitable only for very accurately worked prisms, it is hoped to attain an accuracy of a small fraction of a second. Among the other exhibits were an improved Lovibond colorimeter, various instruments for measurements of focal lengths and curvatures, and an interference test of the surface of glycerine showing that such a surface, even when left undisturbed for many weeks, does not become flat.

The metrology department demonstrated optical tests on the flat faces of end gauges for determining flatness, parallelism, and squareness to axis of gauge. An optical proof plane is held opposite one end of the gauge and rotated about two perpendicular axes lying in its own plane. The appearance of the interference fringes formed between the proof plane and the end face of the gauge gives an indication of the state of perfection of the flatness of the face. By observing any change in the interference pattern as the gauge rotates about its own axis, the test of squareness of the face to the axis is obtained. The method of testing the flatness of a large surface consists essentially of the comparison of the surface to be tested with the horizontal free surface of mercury.

Other exhibits in this department were a standard leading screw lathe, line standards, and a method of determining the length of an end gauge with reference to a standard scale.

In the William Froude national tank experiments were conducted in connection with the manœuvring power of ships. The experiments may be divided into two main sections, the action of the water on the rudder of a ship, which will vary with ship form features, type of rudder, etc., and the action of the rudder forces on the ship as a whole. Measurements are taken of the water moments on the rudder stock and on a second axis of the rudder, with and without propeller working, and of the initial torque on the hull, with the rudder over to any angle.

The photometry division of the electricity department showed a method of determining the distribution of light from the lenses used in ships' navigation lights. Apparatus was also shown for the polar distribution of light. This is of the ordinary two-mirror form, but with special arrangements for the ready rotation of the mirror, the holders for which rotate on ball bearings. Another exhibit was the integrating sphere photometer. This is an Ulbricht sphere of 1 metre internal diameter, which has been designed for the measurement of lamps of ordinary commercial sizes.

The exhibits in the wireless division included closed-coil wireless direction-finding systems. The particular coil exhibited was designed and constructed at the laboratory, and is believed to be the first direction-finding coil system ever employed on aircraft, having been used for some experiments at Cranwell in 1916. A complete wireless direction-finding station was shown in operation, the set exhibited being identical with those installed by the Radio Research Board at various universities in the British Isles for experimental investigations.

There were other numerous interesting exhibits in this department, such as the Schuster magnetometer; transformers and ovens for experiments on cables at high temperature and high potential; and methods of measuring the heating of cables buried in the ground under various conditions.

Scientific Publications for Russia.

IT will be remembered that when Mr. H. G. Wells visited Petrograd in November last he found that the remnant of Russian literary and scientific workers who had survived the revolution had been brought together by the Soviet Government and housed in two institutions in Petrograd. There the scientific workers were carrying on their researches as best they could in the face of great privations owing to lack of food and clothing. What they felt even more keenly was that they were cut off from men of science outside Russia and were unable to obtain scientific literature or apparatus.

A committee was therefore formed in December under the title "The British Committee for Aiding Men of Letters and Science in Russia" to obtain some of the chief publications required. An appeal, which was published in NATURE of January 6, p. 598, was made for funds to help the project forward.

Prof. Oldenburg, permanent secretary of the Petrograd Academy of Sciences, was communicated with, and was able to provide the committee with a list of the works which were urgently required. This list contained a number of works issued by British and other publishers, together with the publications of many learned societies. The committee then communicated with the leading scientific societies which had sent their publications into Russia before the revolution, and several entrusted their publications to the committee for transmission to the House of Science in Petrograd. A number of British publishers presented volumes for the same purpose, and help was also given by universities and publishers in the United States. In addition the committee has acquired books by purchase and by gift from private individuals.

Naturally very careful inquiries were made from both the British and the Soviet authorities as to the prospect of the books reaching the men for whom they were intended. Every assurance was given that delivery would not be interfered with, and several cases of books were accordingly dispatched. It was feared that in spite of their assurances the Soviet authorities would confiscate the literature, and it is therefore gratifying to learn that an acknowledgment of their safe arrival has been received from Prof. Oldenburg. A book-list which was also dispatched has been returned signed by several notable Russian men of science, so there is now little doubt that the books were received by those for whom they were intended.

It is thought that fear of miscarriage of these books has prevented the co-operation of many well-wishers of the scheme. Now that this fear is allayed it is hoped that further subscriptions and donations will be forwarded to the treasurer of the committee, Dr. C. Hagberg Wright, the London Library, St. James's Square, S.W.1.

Friendship.

(To T. H. R.)

WERE life an empty bubble blown by chance
To glitter, mount, and burst beyond repair;
Were mind delusion, fancies rich and rare
Mere exhalations, firefly effluence;

Or should this mood be but the spirit's trance,
And one enduring Whole his Being share
By ordered gradients up the thronal stair
From atom fires to soulful radiance;

Be all philosophy beyond our ken
And nothing certain,—yet, as star draws star,
As bubbles meet and cling, electrons blend,
There sings a joy when friend meets parted friend,
Time's limitations yield, and past the bar
Life's transcendental portals ope again.

WALTER GARSTANG.

June 19, 1921.

Conference of American and British Engineers.

THE four leading engineering societies of the United States of America recently combined to form the United Engineering Society, to promote the more general interests of the profession. Fifteen delegates from these societies have come to London, partly to bring a greeting and message of friendship to British societies, and partly to present the John Fritz medal, the greatest honour the American societies can confer, to Sir Robert A. Hadfield, Bart.

The chairman of the delegation is Mr. Ambrose Swasey, who is not only a constructor of the finest machine-tools, but also the builder of the great telescopes at Mount Hamilton, at the Naval Observatory, Washington, and at the Yerkes Observatory, Wisconsin. He also built the 72-in. reflecting telescope of the Dominion Astronomical Society at Victoria (B.C.). Among the delegates are Col. A. S. Dwight (American Institute of Mining and Metallurgy), Mr. C. F. Rand (secretary of the board which awarded the medal), Dr. Ira N. Hollis (American Society of Mechanical Engineers and president of the Worcester (Mass.) Polytechnic Institute), Mr. C. T. Main (American Society of Mechanical Engineers), Dr. F. B. Jewett (American Society of Electrical

Engineers and chief engineer of the Western Electric Co., of Chicago), Mr. I. R. Freeman (American Society of Mechanical Engineers), and other distinguished engineers.

Advantage was taken of the opening of conferences at the Institution of Civil Engineers on June 29 to receive the delegates. Mr. John A. Brodie, president, welcomed the American engineers, and suggested the formation of an engineering committee to investigate the question of stoppages in production and methods for the judicial treatment of matters in dispute.

Dr. Ira N. Hollis then in an eloquent address conveyed the friendly wishes of American engineers. Those present, he said, belonged to a profession which had, through its inventions and its work, laid the foundations on which civilisation had been built. Engineers stood side by side on the battlefield, and American engineers took pride in the share of their British colleagues towards the victory for truth and justice when much that had been gained by centuries of struggle seemed likely to be lost and the freedom of the world was in danger. The great issue of the twentieth century was the right of every man to earn a living and develop his possibilities without being controlled by powerful combinations of any kind. No family and no line of families should find the door of opportunity shut. He looked forward to the day when not only American engineers, but all engineers would be banded together for the welfare of the world. He was sure that Darwin would turn in his grave if he could but know how evolution had been twisted by the Teutonic mind into glorifying war as a developer of the race. Dr. Hollis then read the address from the American societies. It expressed the feeling of brotherhood and a sense of the loss in the death of so many British colleagues on the battlefield. The American engineers rejoice to have been permitted to share with other engineers the victory over a war spirit dangerous to the rights and happiness of men.

The president of the Institution of Civil Engineers accepted the address, and Dr. W. C. Unwin, in reply to Dr. Hollis, said that the delegation which had come with so gracious a message were missionaries of kindness. British engineers recognised the great advances in engineering science in America, and admired immensely the great works of construction there carried out. In the war the United States had come to our assistance with its great manufacturing resources. The supplies of steel it sent were of immense value, and not less valuable were the remarkable machine-tools for which the United States was famous. We had been linked in war, and would not fail in trying to stabilise peace; so far as one generation could, we must endeavour to make such a war impossible in the future.

Lord Bryce laid stress on the international character of the engineering profession. Men of science belonged to the world and worked for the world, and were welcomed by their colleagues wherever they went.

Mr. Ambrose Swasey then presented the John Fritz medal to Sir Robert Hadfield. Mr. Swasey said that the delegation represented the four American national societies of civil, mining and metallurgical, mechanical, and electrical engineers. The John Fritz gold medal was instituted by the friends of the great American engineer, John Fritz, for his achievements in industrial science, and was awarded annually. Lord Kelvin and Sir William White had both received the medal previously in honour of their achievements. The award this year had been made to another distinguished engineer in Great Britain, Sir Robert Hadfield, in recognition of his scientific attainments and his eminence in metallurgical research, and for the distinguished service he had rendered in the invention and perfection of manganese steel.

In his reply Sir Robert Hadfield said that he was deeply moved by the demonstration of goodwill shown by the great honour conferred upon him by the American engineering profession. In the official announcement of the award he had been told that the distinction should be accepted by him not only for himself personally, but also, through him, as an expression to the British nation, on the part of American engineers, of their high regard and appreciation of the work of the British engineer in the war for the preservation of civilisation. That message was indeed cheering, and was a harbinger of good for the future of the race. Sir Robert thanked the delegation for its courtesy in coming to this country, when he ought to have gone to America, but considered that his inability to do so was a blessing in disguise, as evidenced by the great gathering that day. It was a great pleasure to have present their American friends, because it was in America that manganese steel first received encouragement on a large scale. It was also appropriate that the award should be made in the hall of the Institution of Civil Engineers, since his first papers in 1888, giving account of the invention of manganese steel, had been presented in the hall of the old building of the institution.

Our readers will be interested to know that Sir Robert Hadfield has had printed an address of thanks. This address contains much interesting information respecting eminent engineers, with portraits, on both sides of the Atlantic, together with illustrated notes on the founding and work of the Royal Society.

The work of the conference was carried out in seven sections:—(1) Railways, roads, bridges, and tunnels. (2) Harbours, docks, rivers, and canals. (3) Machinery. (4) Mining and metallurgical processes. (5) Shipbuilding. (6) Waterworks, sewerage, and gasworks. (7) Electricity works and power transmission. Some fifty-five papers of notes were introduced and discussed. Reference to a few of these only can be made here.

Mr. Alexander Ross laid down as propositions for discussion that on our railways the 6-ft. space should be widened to 7 ft.; if there are more than two lines of rails, the space between the original pair of rails and additional rails should not be less than 11 ft. 6 in. No overhead structure should have less clear headway than 15 ft. 6 in. above the top surface of the rails. No structure higher than 2 ft. 6 in. above rail-level should be nearer to the edge of the nearest rail than 5 ft.

Mr. Oswald G. C. Drury described the use of the Ingersoll cement-gun in carrying out repairs on the Cliftonville tunnel. The next few months will show the value of this method of grouting, but Mr. Drury thinks that the method is a practical success from the point of view of stability and speed, although the commercial value has yet to be thoroughly tested.

Mr. William W. Grierson gave particulars of the now extensive use of reinforced concrete on British railways. The use of fence-posts of this material is largely on the increase. Various designs of reinforced concrete sleepers have been experimented with, but none are successful under heavy and frequent traffic at high speeds.

The important question of the best way of protecting reinforced concrete from marine deterioration was introduced by Mr. Francis E. Wentworth-Sheilds. Our experience of this material for maritime structures now extends over twenty years, and there have been several failures. These are owing to: (*a*) The concrete has become softened by the chemical action of the sea-water. (*b*) The concrete has scaled off owing to the action of frost. (*c*) The concrete has worn off by attrition by travelling shingle and stones. (*d*) The concrete has split and cracked by the rusting of the enclosed steel and its consequent increase in volume. The last is the most common type of failure.

Mr. George E. W. Cruttwell presented an interesting note on the use of a model for investigating the movements in the River Thames between Teddington and Shoeburyness. The first model of this kind was employed by Prof. Osborne Reynolds, and the present improved model gave very good results. Mr. Cruttwell suggests that the greater part of the model and the whole of the working apparatus could be adapted for experimenting with other estuaries at a trifling cost, and that it would be most advantageous to the engineering profession if the National Physical Laboratory or some similar institution could install the necessary apparatus, which could then be adapted to suit any particular case. The cost of the Thames model was about 300*l*., and a moderate fee would cover the cost of the necessary adaptations and investigations.

In dealing with the bearing power of soils Mr. Arthur L. Bell made reference to the various theories of earth-pressure. Advance in earthwork problems had been, in the main, due to individual experiment and speculation, and Mr. Bell considers that the best hope for the future lies in the encouragement and aid of individual inquiry. Engineers seek a sound and preferably simply theory which can be successfully applied, not to one only, but to all the multitudinous varieties and conditions of soil.

The influence of the automatic and semi-automatic machine on the skill and resourcefulness of the mechanic and operator was the subject of a note contributed by Mr. Arthur H. Hall. Such machines are set ready for work by a skilled mechanic and operated by another person. Mr. Hall considers that the designer has precluded the operator from the display of resource, but that a reasonable amount of skill is required. The mechanic must display great resource, the amount varying with the degree of responsibility allotted to him by the management in the matter of design and lay-out of tools. His skill in making these is of the kind usually expected of a highly trained workman, but in setting them up he may exhibit qualities not readily capable of comparison with those required in other work.

Sir Robert Hadfield presided in the mining and metallurgical section, and said that the world was literally hungering at the present time for a hundred million tons of iron and steel. Iron was the standard of all modern comfort, and to economise in its use meant to reduce our civilisation. Take away this metal, and the world would relapse into almost a state of barbarism.

Dr. John W. Evans introduced the subject of the employment of water-power in the development of the mineral industry. During the war there was a remarkable advance in Sweden, where the number of electric furnaces increased from eight in 1914 to twenty-eight in 1918, and the output of pig-iron obtained from them increased from 5786 tons in 1911 to 75,684 tons in 1918. The day is at hand when electrolytic methods will enable metals to be extracted with commercial success from ores which are too poor to be dealt with by smelting operations.

Fabricated ships were dealt with in notes by Mr. Maurice E. Denny and Mr. John C. Telford. These notes consider the problem from the labour-saving point of view. The premier requirements to make fabricated ship construction a success are several vessels all alike, standardised so as to make the detail reproduce itself many times over; also (*a*) careful work in the drawing office and template loft, (*b*) accurate workmanship in the shops, (*c*) close inspection, and (*d*) the provision of ample means for checking the several parts with jigs and templates as the work proceeds.

Obituary.

ABBOTT H. THAYER.

ALL naturalists, and especially those of the English-speaking world, will learn with great regret of the death of the distinguished and original artist-naturalist, Mr. Abbott H. Thayer, announced in *Science* for June 10. Many of us will lament the loss of a dear friend who sympathised with our sorrows and difficulties as if he had been one of us, and, long before his country joined the struggle on behalf of freedom and civilisation, came to England in the hope that he could induce the authorities to accept his help in the methods of "camouflage" by land and sea.

Thayer's great fundamental discovery was of course the interpretation of the white undersides of animals as the elimination of shadow by counter-shading. I once asked him how he came to think of it, and his answer showed that the discovery sprang from the artist side of his nature. He observed, he said, that animals in the wild state were elusive and ghost-like, and that when the artist wished to paint them so that they might be easily seen in the picture he had to employ an unnatural illumination or to represent them silhouetted against the sky. He was thus led to investigate, and finally to discover, the cause of

this great factor in protective resemblance. The artist in him first saw the well-nigh ever-present effects, and then found the cause, which, indeed, had been suggested some years earlier by one who failed to recognise its far-reaching importance and thus missed a great discovery.

Thayer's artistic temperament also led him to resent any limits to the application of his principles and to attempt to explain by them all examples of warning and mimetic coloration. When the review of the first edition of his work, "Concealing Coloration in the Animal Kingdom," appeared in NATURE (1910), it was many months before he could bring himself to read it. Yet when at length he made the effort he was pleased, and wrote a kindly letter to the reviewer.

Science needs the help of such men whose approach is from a widely different point of view, and science owes much to Thayer and will gratefully preserve his memory. E. B. P.

THE death is announced, at eighty-three years of age, of PROF. VIKTOR VON LANG, formerly professor of physics at Vienna University and a past-president of the Austrian Academy of Sciences.

Notes.

AT the meeting of the Royal Society of Edinburgh held on Monday, July 4, the following were elected honorary fellows :—*British Honorary Fellows:* William Henry Perkin, Sir Ronald Ross, Sir Ernest Rutherford, and Sir Jethro J. H. Teall. *Foreign Honorary Fellows:* Reginald Aldworth Daly (Cambridge, Mass.), Johan Hjort (Bergen), Charles Louis Alphonse Laveran (Paris), Heike Kamerlingh Onnes (Leyden), and Salvatore Pincherle (Bologna).

THROUGH the generosity of the Rev. Dr. Winifrith, of Hythe, a memorial tablet has just been placed on the house—31 High Street—in that town in which Sir Francis Pettit Smith was born. Of all the numerous inventors of screw propellers, Smith, perhaps, is the best known. Born in 1808, he began life as a farmer, but was always given to mechanical invention. His first patent for a screw propeller was dated May 31, 1836, and his screw was first fitted in the *Francis Smith,* and then in the epoch-making vessel s.s. *Archimedes.* Brunel was among the converts to Smith's ideas, and he discarded paddle wheels for the *Great Britain,* which, in 1845, was the first screw-driven vessel to steam across the Atlantic. The same year the screw sloop, H.M.S. *Rattler,* was added to the Navy List, and for some years afterwards Smith was employed by the Admiralty installing his screws in the converted line of battleships, many of which were in service in the Crimean War. He made little money out of his invention, but the shipbuilding and marine engineering world in 1858 raised a subscription of nearly 3000*l.* for him, and gave him the fine silver salver and jug which are in the Science Museum. During the latter part of his life—he died in 1874—Smith was curator of the Patent Office Museum.

GLASGOW UNIVERSITY, in accordance with the policy of establishing separate buildings for its scientific departments which was initiated by the erection of the Botanical Institute, has signed a contract for a zoological building, which has been planned by Prof. J. Graham Kerr and the architects, Messrs. John Burnet, Son, and Dick. The building will be near the new medical department on part of the former athletic ground. It will cover 3000 square yards, and include a lecture-room with accommodation for 260 students, an elementary laboratory with tables for 150 students, and special laboratories for advanced work, protozoology, research, and experimental zoology. There will be a large museum, to which will be transferred the zoological collections now in the Hunterian Museum, leaving space there for extensions of the departments of geology and archæology. Above the museum will be two large tank-rooms for living marine specimens, and land animals will be accommodated in a courtyard. A room will be provided for the departmental library and a suite of rooms for the staff. The building is estimated to cost 130,000*l.*, and it is hoped that the lecture-rooms and laboratories will be ready for the winter session of 1922–23. Under Prof. Graham Kerr the zoological department of Glasgow University has achieved great success, and it will now have a building worthy of its important work.

THE attention of French archæologists is now being devoted to an important series of discoveries in tombs at Martres-de-Veyre, Auvergne, which, according to M. Salomon Reinach, "are in an unprecedented state of preservation. In my experience there has never been found anywhere so many articles of leather, of wool, and of other stuffs in such good condition after being buried in graves for 1800 years." Near this necropolis is the famous fortress of Gergovia, where Vercingetorix won some temporary success against Cæsar, practically the last revolt against the Romans. The extraordinary state of preservation of the bodies found in the six tombs now brought to light calls for explanation. The body of a Gallo-Roman woman interred in a stone coffin lay as if life had only just departed, but on being exposed to the air it suddenly crumbled into dust. Ornaments and articles of the toilet were found in great abundance, while a jar of honey, vases, leather sandals, and linen and woollen fabrics were among the furniture of the graves. The articles discovered have been deposited in the museum at Clermont-Ferrand, the capital of the Department of Puy-de-Dôme, the Paris museums having wisely decided not to enter into competition with the local collections. It may be hoped that careful excavation in this district will lead to further important results.

IN the James Forrest lecture delivered on June 28 Sir George Beilby presented a review of the world's fuel situation. Coal, brown coal, peat, oil from wells

and from oil-shales, and alcohol are discussed, and the conclusion is reached that coal is likely to remain for a long time the world's chief source of fuel. Brown coal and peat are dismissed on account of the vast areas of land which are required in order to obtain adequate supplies and prepare them for use. Oil amounts to 7 per cent. of the fuel output of the world, and nearly nine-tenths of this quantity is controlled by the United States. The conclusion of the chief petroleum technologist of the U.S. Bureau of Mines, that after twenty years at the present rate of consumption the output will decline, is therefore of importance, though there is reason to expect production from oilfields in other parts of the world which have not as yet been tapped. The only method available in Great Britain for the commercial preparation of alcohol is by the fermentation of vegetable materials containing starch or sugar. Even this method, however, is not economically possible owing to the lack of available land for the cultivation of the crops required, the high cost of cultivation, harvesting, and manufacture, and the fact that the most suitable raw materials are also important foodstuffs. Some alcohol may be produced from molasses in countries where the sugar-cane is grown, but it is unlikely that more than is required for local use can be made. Falling back on coal, it is suggested that more efficient use may be secured by careful sorting at the pitheads, by improvements in boiler-firing, and by preliminary carbonisation at high or low temperatures.

THE *Daily Chronicle* announces that Prof. Edouard Branly, of Paris, is to receive this year's Nobel prize for physics.

IT is stated in the *Times* that the directors of the Nobel Foundation have submitted a proposal to the Swedish Government for increasing the value of the Nobel prizes by transferring a sum of about 100,000*l*. from their building fund.

WE learn from the *Times* that the French Société de Géographie is celebrating its centenary. There was a reception for delegates at the house of Prince Roland Bonaparte, president of the society, on Tuesday night, and in the afternoon M. Millerand, President of the French Republic, presided at the opening meeting of the celebration, a gathering at which explorers and geographers from various parts of the world were present.

THE sixty-sixth annual exhibition of the Royal Photographic Society of Great Britain will be held on September 19–October 29 at 35 Russell Square, W.C.1. There will be three sections, devoted respectively to pictorial photographs, to colour transparencies and colour prints, and to scientific and technical exhibits, natural history photographs, and lantern and stereoscopic slides.

A CIRCULAR has been issued by the Meteorological Office with reference to the summer service of forecasts of weather for agricultural purposes. Notification is given by telegraph of occasions when a spell of fair settled weather of several days' duration is anticipated. The progress of meteorological events and warning of the break-up of the fine spell are sent to the recipient as early as possible. The fee beyond the telegraphic charge is extremely small. Notification is also given of special conditions, such as spells of frost, ground-frost, smooth sea, etc.

BY invitation of Messrs. Sutton and Sons and of Prof. Percival, a field-meeting of the Association of Economic Biologists will be held at Reading on Thursday, July 14. Visits will be paid to the Royal Seed Establishment, the Trial Grounds, and the College Farm and Agricultural Botanic Gardens. It is requested that all who propose to attend the meeting will notify Mr. W. B. Brierley, the Rothamsted Experimental Station, Harpenden, not later than Monday, July 11.

BEGINNING on June 15, the wireless telegraph station at Poldhu is sending weather messages broadcast twice daily for the benefit of navigators. Each message will consist of a forecast for the western seaboard of the British Isles and the actual observations taken at Stornoway, Blacksod, Holyhead, Scilly, and Dungeness at 0700 G.M.T. (civil) and 1800 G.M.T. (civil) respectively. The messages will be sent out at 0930 G.M.T. (civil) and 2130 G.M.T. (civil). Details of the scheme are given on the Meteorological Chart of the North Atlantic Ocean for July.

A NORWEGIAN scientific expedition is leaving this summer for the island of Jan Mayen, in the Greenland Sea. According to *La Géographie* for May, the expedition will consist of six or seven persons, under the command of Mr. Ekerold. The main object is meteorological research, and it is hoped that the work of the party will lead to the foundation of a permanent observatory on Jan Mayen. A wireless telegraph station is to be erected. The last serious effort in meteorological research at Jan Mayen was in 1882–83, when an Austrian station, as part of the international scheme, was maintained on that island.

WE are glad to learn that Lyme Regis, a town classic in geology, is now provided with a public collection of local fossils. Three years ago a small museum building was bequeathed to the corporation by the late Mr. Philpot, and it is now occupied by the geological collection and library of Dr. Wyatt Wingrave, who has lately become a resident of the town, and has devoted much labour to making the museum of educational value. The fossils are arranged in stratigraphical order, with appropriate explanatory labels and diagrams, and Dr. Wingrave gives a weekly demonstration which is well attended and much appreciated.

H.R.H. THE PRINCE OF WALES has accepted the office of vice-patron of the Royal Society of Arts. The following medals have been awarded for papers read before the society during the past session:—Major-Gen. Lord Lovat, "Forestry"; Col. R. J. Stordy, "The Breeding of Sheep, Llamas, and Alpacas in Peru, with a View to Supplying Improved Raw Material to the Textile Trades"; A. F. Baillie, "Oil-burning Methods in Various Parts of the World"; Dr. W. Cramp, "Pneumatic Elevators in Theory and Practice"; Sir Kenneth Weldon Goadby, "Immunity and Industrial Disease"; W. Raitt,

"Paper-pulp Supplies from India"; Sir George Curtis, "The Development of Bombay"; A. H. Ashbolt, "Industrial Development in Australia during and after the War"; and Sir Charles H. Bedford, "Industrial (including Power) Alcohol."

WE have received a communication from Mr. W. J. Lewis Abbott in reference to a statement made in the course of the discussion on Mr. Reid Moir's paper on "An Early Chellean Palæolithic Workshop-site at Cromer," which took place at a meeting of the Royal Anthropological Institute (see NATURE of May 26, p. 406). In that discussion one of the speakers stated that the flints in question were "no more than a foreshore accumulation of flints which differed in no way from other flints found on the foreshore along the whole East and South Coast." Mr. Abbott directs attention to the distinctive coloration of the Cromer specimens, of which there are three types: (1) Those which are porcellanised or whitened; (2) those exhibiting the characteristic orange-red colour; and (3) specimens which have been changed from white to black, the white porcellanous condition being present under the black. He maintains that this peculiar feature cannot be due to beach action. In regard to the evidence for dating the finds, Mr. Abbott states that he has discovered specimens in association with remains of *Elephas* (?) *meridionalis*, in one case *in situ*. The question of the coloration of the Cromer flints is one of considerable difficulty, for which no satisfactory explanation has yet been offered, while in regard to the stratigraphical evidence, it is clear that a systematic investigation at the base of the Forest Bed series on this site, as suggested by Mr. Reid Moir himself, is extremely desirable.

"SUN-SPOTS and Weather" is the title of an article in the *Meteorological Magazine* for June, dealt with by Mr. C. E. P. Brooks. It is mentioned that the subject is again opened by the recent development of an unusually large sun-spot with associated electrical and magnetic phenomena. A bibliographical list is given of authorities on the subject, and the author states that although the literature is enormous, we are still far from definite conclusions. So long ago as 1651 Riccioli claimed that temperature rose with decreasing sun-spots and *vice versa*. The discovery in 1844 of an eleven-year periodicity in spots caused a renewal of the study, and in 1873 results of an investigation by Köppen were published showing that temperature reaches a maximum shortly before spot minimum and a minimum about spot maximum. A positive correlation of sun-spots with rainfall has been found in the tropics, and also with elements such as lake levels which depend on rainfall. A close parallelism has been demonstrated between sun-spots and tropical hurricanes, and the author states that the study of eleven years' wind data in the Falkland Islands suggests that at spot maximum the storminess is greatest.

POPOCATAPETL exhibited only slight activity in the way of fumaroles and solfataras in the two centuries that followed the eruption of 1720. In 1920, however, small eruption-clouds became visible from Mexico City, and Mr. Paul Waitz has described an ascent made by him in October last (*Amer. Journ. Sci.*, vol. cci., p. 81, 1921). Considerable outbursts of steam were then taking place from the crater, accompanied by a small quantity of stones and ashes, and

FIG. 1.—Cauliflower clouds of a steam eruption of Popocatapetl, October 12, 1920. From the *American Journal of Science*, January, 1921.

it appears that the old central plug of 1720, formerly concealed by a lakelet, is now being pushed upward in the crater-floor. Two fine photographs accompany the paper, one of which is here reproduced.

THE current issue of the Journal of the Institute of Petroleum Technologists contains, among other papers, some interesting details by Capt. Paul H. Mangin on boring in Palestine in search of water during the progress of military operations from 1917 to 1919. Although both drilling *personnel* and equipment were initially somewhat crude, very creditable results were achieved, no less than a gross total of 5500 ft. being drilled in the putting down of forty-five wells, from which something like 1,500,000 gallons of water per day were obtained. The area in which the wells were sunk borders the coast between the Egyptian frontier (at Rafah) and Mount Carmel on the north. The chief difficulties encountered apart from those mentioned were the loose nature of the sands penetrated and the prevention of their caving in and blocking up the hole. Five types of drilling rig were used, but the best results were obtained by the hydraulic percussion system with mud flush. An important feature of the work was the excellent log kept of each well, which, together with samples of the formations met with, have been preserved for future reference. Although having no

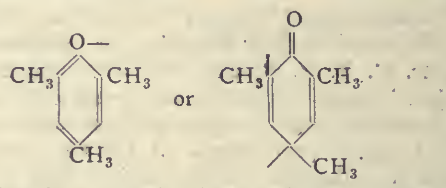
direct bearing on oil, the results of this work are of great interest to petroleum technologists generally, and also presumably to those who are optimistic enough to believe in Palestine as a potential oilfield.

Part 2 of vol. xxii. of the Transactions of the Optical Society contains the address of the president, Mr. R. S. Whipple, which deals with the design and construction of scientific instruments. Such instruments must have as their principal characteristic the property of giving results of a constant prescribed accuracy, and all the important sources of inaccuracy in them should be known. Errors should be capable of elimination by adjustment of the instruments themselves, or if elimination is not possible, they should be measurable by the instruments. The design of an instrument involves the consideration of the magnitudes of the errors to which it may be liable, and it is this preliminary survey which prevents the cost of manufacture being increased by the removal of insignificant errors while others more serious are allowed to remain. Examples of well-designed slides, rotating parts, screws, and nuts are given, and it is clearly shown why they are good. A nut of unsound design used on gun clinometers which the authorities preferred to one designed on geometrical principles is also shown. The address will repay reading by all instrument-makers who wish to meet the new demand for scientific instruments in industry.

The fourth report of the Conjoint Board of Scientific Societies shows that the board has received evidence that scientific investigation is being seriously hampered by the heavy cost involved in the publication of results. An exceptional number of papers is being communicated to the scientific societies, including many held up during the war, while the resources of the societies, which have not increased, are insufficient at present prices to publish even the normal prewar number. The country is thus in danger of being seriously handicapped at a time when the rehabilitation of industry is in most serious need of scientific assistance. Much of the report is occupied with an abstract of the third report of the Committee on the Water-Power Resources of the Empire. It is shown that too little is being done to ascertain the total resources or to secure uniformity in investigation and record. It is urged that steps should be taken to convene an Imperial Water-Power Conference in London, at which the various Dominions and Dependencies of the Empire should be represented. The outcome of such a conference might well be the creation of an Imperial Water-Power Board, with extensive powers to carry out a comprehensive policy for stimulating, co-ordinating, and, where necessary, assisting development throughout the Empire. The board has also dealt with questions relating to the formation of national research committees in connection with the International Research Council formed in 1919, with the collection of scientific data in the former German colonies, and with instruction in technical optics. The research on glues and other adhesives initiated by the board as a war measure, at the instance of the Air Ministry, has now been taken over by the Department of Scientific and Industrial Research.

The trials of the motor vessel *Yngaren* were run successfully off the Tyne on Tuesday, June 14, and an account appears in *Engineering* for June 24. The main engine of this vessel is of the opposed piston type, with four cylinders 22·8 in. diameter by twice 45·6 in. stroke. When running at its normal speed of 77 revs. per min. the engine develops 3000 indicated horse-power (2700 brake horse-power), or 675 brake horse-power per cylinder, and is therefore the highest-powered Diesel cylinder as yet installed in any ship. The ship is also notable on account of having but one propeller. In view of the large power per unit and of there being but one engine, the designers were conservative, and the metal and sections are more than ample for the working stresses, with a large factor of safety. The weight of the main engine is 375 tons, and of the whole installation 600 tons. Starting is exceptionally easy to accomplish, and contributory to this result are hot pistons and hot jackets. During the sea trials the outlet temperatures from the pistons and cylinder jackets were 140° to 160° F. The fuel injection into the main engine cylinders works on the solid injection principle, and is effected at pressures of 8000 to 10,000 lb. per sq. in. at full power and speed.

The preparation of a compound which may contain univalent oxygen is announced by C. W. Porter and F. H. Thurber, of the University of California, in the April issue of the Journal of the American Chemical Society. The substance is obtained by the oxidation of mesitol (2 : 4 : 6-trimethylphenol) by silver oxide. A red crystalline product was obtained, the molecular weight of which indicated that it contained in combination equimolecular amounts of unoxidised mesitol and an oxidation product corresponding to one of the formulæ:



It may, therefore, contain either univalent oxygen or tervalent carbon. It is reduced to a saturated product by the addition of an uneven number of hydrogen atoms, indicating that it contains an odd electron, and has therefore the characteristic properties of a free radical.

In consequence of the greatly increased cost of production, the Association of Economic Biologists has issued an appeal for financial assistance towards the publication of the eighth volume of the *Annals of Applied Biology*. In order that the present standard of quality of the *Annals* may be maintained, it is necessary that the sum of 250*l*. should be raised. Workers in applied biology are therefore earnestly invited to contribute to the appeal fund. Any contribution, however small, will be acceptable, and should be sent to the honorary treasurer of the association, Dr. A. D. Imms, Institute of Plant Pathology, Rothamsted Experimental Station, Harpenden.

Messrs. Macdonald and Evans, 29 Essex Street, W.C.2, are about to begin, under the editorship of Mr. G. W. de Tunzelman, the publication of a new

series of manuals entitled "The Reconstructive Technical Series," the aim of which is to diffuse the new knowledge and enlarged technical skill gained during recent years, and so to make it available for to-day as a means towards greater all-round efficiency and increased competitive power in the world's markets. The first volume—"Engineering Steels: An Exposition of the Properties of Steel for Engineers and Users to Secure Economy in Working and Efficiency of Result," by Dr. L. Aitchison—will be published almost immediately.

IN recent correspondence on the subject of picture-hanging wire, copper or brass wire has been recommended. Mr. N. M. Richardson now writes to condemn these materials for this purpose on account of the brittleness which develops in the course of a few years. He advises the use of galvanised iron wire, which can be painted a suitable colour if desired. Such wire has been found to be very trustworthy and permanent unless it is exposed to damp.

ADMIRERS of the late Sir William Abney will be interested to learn that the Abney memorial lecture by Mr. Chapman Jones (delivered before the Royal Photographic Society of Great Britain on April 26 last) is printed in full in the July issue of the *Photographic Journal*. Copies of the journal are obtainable from the publishers, Messrs. Harrison and Sons, Ltd., 45 St. Martin's Lane, W.C.2, or the Society, 35 Russell Square, W.C.1.

WE have received from Mr. R. S. Frampton, 37 Fonthill Road, N.4, a catalogue (No. 26, 1921) of second-hand books dealing with science—mainly natural history and gardening. Some 1056 works are listed, and the prices asked are low. The catalogue is obtainable upon application to the bookseller.

MESSRS. GEORGE BELL AND SONS, LTD., announce the publication by them in the autumn of a full report of the proceedings of the Congress of the Universities of the Empire now in progress.

Our Astronomical Column.

THE CAPE OBSERVATORY.—Expression is given by Sir Joseph Larmor, in a letter to the *Times* of July 4, to the apprehensions that are felt among astronomers as to the effect of the proposed transference of the Cape Observatory from the Admiralty to the South African Government. Judging by the condition of the Australian observatories, which at all stages of their existence, and never more than at present, have been greatly hampered through lack of funds, the change would not be to the advantage of astronomy. Further, the suggested transfer would greatly weaken the close bond of reciprocity that has from the first linked the Greenwich and Cape Observatories. It is greatly to be desired that the proposal, which would be little short of a disaster to astronomy, may yet be averted.

THE COMET PONS-WINNECKE.—This comet has now passed out of sight of northern observers, but ephemerides have been sent to southern observatories, where it may be observed for two or three months more. Mr. G. Merton has revised the orbit by using observations extending from April 12 to June 2. He finds

$$T = 1921 \text{ June } 12{\cdot}8985 \text{ G.M.T.}$$

$$\left.\begin{aligned} \omega &= 170^\circ\ 12'\ 34'' \\ \Omega &= \ 98^\circ\ 12'\ 37'' \\ i &= \ 19^\circ\ \ 1'\ \ 7'' \end{aligned}\right\} 1921{\cdot}0$$

$$\begin{aligned} \log a &= 0{\cdot}52957 \\ e &= 0{\cdot}69242 \\ q &= 1{\cdot}0411 \end{aligned}$$

The most uncertain element is $\log a$, for which the above value is almost certainly too large. It gives a period of 6·23 years, whereas the true value is unlikely to exceed 5·93 years. But the other elements would not be greatly altered by this change.

Mr. Denning writes:—"On the night of June 28 I saw some bright meteors, several of which presumably belonged to the shower from Pons-Winnecke's comet. It is desirable to procure duplicate observations of these objects if possible, for the purpose of working out their real paths, and ascertaining whether or not their radiant points nearly coincide with that computed for the above comet.

"The following are the times and apparent paths of six of the more noteworthy meteors seen here, and if any of them have been observed elsewhere I shall be very glad to receive such details as were recorded. It need only be said with reference to the objects that No. 4 in the list was a splendid fireball, and that No. 5 is included on account of its exceedingly slow motion. No. 2 was not accurately observed, owing to its flight being partly intercepted by a building. Nos. 1 and 4 were directed from radiants far distant from that of Pons-Winnecke.

Meteors recorded June 28, 1921.

No.	G.M.T. h. m.	Mag.	From ° °	To ° °	Notes.	Radiant ° °
1	11 49	> ♃	$236+48\frac{1}{2}$	$212+45\frac{1}{4}$	Rapid, streak	303+24
2	11 56	> 1	$318-1$	$327-7\frac{1}{2}$	Slow, white	? P.-W.
3	12 22	1	$293+15$	$298+5$	Slowish	P.-W.
4	13 18	5 × ♀	$339+33$	$348+18$	Slow	P.-W.
5	13 30	2	$311+67$	$330+61$	Very, very slow.	P.-W.
6	13 34	♃	$319+19\frac{1}{2}$	$312+2$	Rapid, white	70+66

THE FIGURE OF THE EARTH.—An article on this subject by Prof. T. J. J. See (*Astr. Nach.*, Nos. 5103–4) is interesting as an historical summary of the progress of knowledge on the subject. Sir Isaac Newton recognised that the compression was considerably less than 1/230, the figure for equilibrium with a homogeneous fluid earth. The three chief methods have been (1) the measurement of arcs of latitude, (2) lunar perturbations, and (3) pendulum observations. In 1751 La Condamine published the value 1/303·6, deduced from measurement of arcs of latitude in France and Peru. In 1802 Bürg found the value 1/305·05 from method (2). These two values were surprisingly good for that early period, but still not entitled to any weight compared with modern determinations, although Prof. See assigns some to them. The figure 1/293·465 was published by Clarke in 1878, and generally superseded Bessel's value of 1/299·1528, although the latter now appears to be closer to the truth. In recent years methods (1) and (3), in the hands of Helmert, Hayford, Bowie, and others, have given very consistent results, from which the weighted mean 1/298·3 is deduced. Prof. See gives a useful table for obtaining geocentric latitude and radius vector on this assumption, and notes that in his opinion the value 1/294, adopted in Brown's Lunar Tables, is decidedly too large.

Sir Ernest Shackleton's New Expedition.

SIR ERNEST SHACKLETON announces in the *Times* and *Daily Mail* a new Antarctic expedition to start under his leadership in August. The region to be explored is that missing part of the Antarctic coastline which lies between Drygalski's Wilhelm Land and Bruce's Coats Land. In this stretch the only land known with certainty is the bold headland of Cape Ann, or Enderby Land, discovered by J. Biscoe in 1831, but never visited. Cape Ann probably marks the edge of the continent. Kemp Land, a little further east and also on the Antarctic Circle, was reported in 1833, but its existence needs verification. Cook (1773), Biscoe (1831), Bellingshausen (1820), and Moore (1845) were each thwarted by pack in their attempts to push southwards to the west of Cape Ann. In lat. 68° 5′ S., long. 16° 37′ E., Bellingshausen was probably not far from land, but these early navigators took no deep soundings. A large bight in the coastline in this region is improbable, but glacier tongues may occur, and, by obstructing the free movements of the pack along the coast, make approach and landing difficult. Sir E. Shackleton hopes to avoid wintering in the south, and plans to sail northwards from Coats Land through the more open eastern part of the Weddell Sea to the South Sandwich group and South Georgia. After refitting he proposes to sail eastward *via* Bouvet and Heard Islands to New Zealand, taking deep-sea soundings on the way. It will prove no easy matter to sound in the stormiest seas in the world, but it is to be hoped he will be successful and so amplify the work of the *Valdivia* and *Scotia*, and further east that of the *Challenger* and *Gauss*. On the way home soundings are to be taken in high latitudes in the south-eastern Pacific.

In addition to his Antarctic work Sir E. Shackleton proposes to visit a number of isolated islands and to search for others the existence of which is doubtful. In the latter category is Dougherty or Keates Island, which was reported in lat. 59° 40′ S., long. 110° 45′ W., in 1841, and since has been sighted only once and several times searched for in vain. It probably has no existence. Search is also to be made for Tuanaki, a legendary island in lower latitudes in the South Pacific. Of the other islands in the expedition's list, a few afford scope for exploration, but others are well known, even if seldom visited. St. Paul's rocks, near the Equator, have been explored by a number of scientific expeditions, from that of the *Beagle* (1832) to that of the *Scotia* (1902). Their geology, birds, and scanty plant-life are well known. South Trinidad achieved fame from Mr. E. F. Knight's cruise in the *Alert*, and was visited in 1902 by the *Discovery*; little new can be expected there. Gough Island, or, more correctly, Diego Alvarez, 280 miles south-east of Tristan da Cunha, promises more interest. The only scientific expedition that has ever visited that island was the *Scotia*, which in 1904 secured several new species of birds and plants. Heard Island was explored by the *Challenger*, but Bouvet Island, discovered in 1739, and sighted again and even photographed in 1898, is quite unknown. It appears to be ice-capped and is said to be inaccessible. Interesting work will be done in the South Sandwich group, which is imperfectly explored, even if known to sealers at one time. In South Georgia work remains to be done on the east and south coasts.

The expedition is to be equipped for oceanographical work, which will be conducted throughout the voyage. Meteorological research will be assisted by the use of a specially constructed seaplane and pilot balloons.

In the *Quest* the expedition has a first-rate ship for the work. She is a Norwegian wooden vessel of some 200 tons, built four years ago, and thoroughly tested in hunting and trading in the Barents Sea and Spitsbergen waters. The *Quest* has auxiliary engines, and will be rigged as a brigantine. Sir E. Shackleton will be accompanied by six members of his former expeditions, including Mr. F. Wild, Capts. F. Worsley and J. R. Stenhouse, Dr. A. H. Macklin, and Mr. L. Hussey, meteorologist. No other names of the staff are announced, but the *personnel*, which is to be small, is said to be complete. The expedition is financed by Mr. J. Q. Rowett, and will be styled the Shackleton-Rowett Oceanographical and Antarctic Expedition. Mr. F. Becker has also given generous support.

R. N. R. B.

Milk Customs of Bunyoro, Central Africa.

ON June 21 the Rev. J. Roscoe read a paper on "The Milk Customs of Bunyoro," at a meeting of the Royal Anthropological Institute. Mr. Roscoe, after a brief account of the distribution of the main groups of peoples in Central Africa, described the chief social and religious ceremonies of the Bunyoro, of which the ritual of the milk formed a part. These ceremonies have become obsolete under the influence of Christianity, but they were revived and re-enacted so far as possible in order that Mr. Roscoe might have an opportunity of witnessing them.

The King of Bunyoro is expected to put an end to his own life as soon as he feels his powers failing through illness or old age. His death is announced by one of the milkmen of the sacred cows in the words, "The milk is spilled," pronounced from the roof of a hut and accompanied by the breaking of a pot of milk. This man and the boy whose duty it is to bring the cows to the royal enclosure to be milked are thereupon put to death in order that their spirits may serve the king in the next world.

The princes who lay claim to the throne now take to arms and fight until only one is left alive. This survivor claims the body of the king, which lies in the royal enclosure unburied until he comes. Mourning then begins, and the dead king is buried in a pit filled up with barkcloths in a specially built hut. Two of his widows are buried alive with him. The country is then purified by the new king's sister, who sprinkles the people and cattle gathered in the royal enclosure with a mixture of water, white clay, and milk. A sham king is appointed for the purpose of removing sorrow and sickness. He is set on the throne, receives homage and gifts, and is then taken aside and strangled by the chief minister. The new king then moves to a new royal enclosure and begins his reign.

The king, as the chief priest for the people and cattle, has a constant succession of ceremonial duties to perform. His food is milk from nine sacred cows brought in from the royal herd and milked with much ceremony. While the king drinks everyone in the royal enclosure kneels down and hides his face; a cough or sneeze is punishable by death. Later in the day the king has a meal of four pieces of meat served by the royal cook, who has to place them in the

king's mouth with a fork; should the fork touch the king's teeth the cook is instantly put to death. All who have to do with the king's food, either milk or meat, are specially purified, and have their faces, chests, and arms whitened. Daily the king has to pass through a series of seven sacred huts for the purpose of herding three of the sacred cows in a special enclosure. The rest of the day he is occupied largely with royal duties, receiving and judging his people.

At every appearance of the new moon there are festivities which last nine days. The king, as soon as the new moon appears, pronounces a blessing on the people, and dancing and music begin, continuing day and night for a week. On the second day the king proceeds through the seven sacred huts to the place where he daily herds the sacred cows, and there he receives any member of the Sacred Guild who has offended. The mark of pardon is to be allowed to kiss the king's hands, and, however kindly the king may address the man, unless he holds out his hands to be kissed, the man knows that he has only a few days to live.

The admission of a new chief to the Sacred Guild is also a milk ceremony of importance, for the new chief has to drink some of the king's sacred milk in the presence of the king. The experience is so trying that men sometimes faint under the ordeal.

The king holds an annual celebration of his accession to the throne, when to defeat his enemies he shoots arrows to each quarter of the globe from a special bow strung with sinews cut from the shoulder of a living man. Once a year also the king calls for a blessing on the land by offering pieces of meat to each of the four quarters of the globe.

In reply to questions asked after the reading of the paper, Mr. Roscoe said that the reason for these ceremonies, as given by the natives themselves, was purely economic. The aim was to promote the well-being of the cattle and the crops.

Trees and Shrubs of Mexico.

THE first instalment of an account of the woody plants of Mexico, by Mr. Paul C. Standley, is issued as vol. xxiii., part 1, of the Contributions from the United States National Herbarium. The work is based upon the extensive series of Mexican plants in that institution. The botanical features of Mexico have attracted attention from the days of the earliest explorers, and many botanists have visited the country within the last hundred years, yet the flora is still but imperfectly known. The plant formations are remarkably diverse, including the wet tropical forests of the southern lowlands, the temperate deciduous and coniferous forests of the central plateau and of the ranges of the Sierra Madre, the alpine zones of the high peaks like Orizaba and Popocatepetl, and the great barren or cactus deserts in the northern States. For anything approaching a complete account of the flora of Mexico we have hitherto had to rely on Dr. Hemsley's list in the "Biologia Centrali-Americana," published nearly forty years ago; much botanical work has been done in the country since that time, and a descriptive flora which will give an account of present knowledge and serve as a starting-point for further work is a desideratum.

Mr. Standley deals only with the trees and shrubs, the larger number of which, especially those of economic importance, are probably already represented in herbaria. In his introduction he gives an interesting account of several of the earliest enterprises for the botanical exploration of Mexico, including that of Francisco Hernandez, 1570–77, and that of Martin Sessi and Jose Mocino more than two centuries later. Large collections of plants and sketches were made in connection with both these expeditions, and extensive accounts prepared in manuscript, but the work of Hernandez was not published until long after his death, and then only in an abridged form; while Mocino's "Plantæ Novæ Hispaniæ" and "Flora Mexicana" were issued by the Sociedad Mexicana de Historia Natural in 1886 and 1888 respectively, by which time their interest had become merely sentimental.

The present instalment of Mr. Standley's work deals with the ferns, gymnosperms and monocotyledons, and a few families of dicotyledons. By an oversight no clue to the general systematic arrangement has been given; there is an elaborate key to the families, which should have been given numbers. Keys to the genera are supplied under each family and to the species under each genus; references to the original description of genus and species are given, the range of each species so far as it is known is indicated, and in some cases short descriptive notes are added; the native names and economic uses are also mentioned. The ferns (elaborated by Mr. W. R. Maxon) are nearly all tree-ferns; the conifers include twenty-six species of pine, and a few cypresses, junipers, ephedras, and others. There are a few grasses—bamboos, reeds, etc.—eighteen genera of palms, and, though strictly herbaceous, three genera of climbing aroids are included. Prof. Trelease has been largely responsible for the account of the liliaceous and amaryllidaceous plants, types characteristic of dry country, including the yuccas and agaves, species of the latter genus numbering 170. The dicotyledons include fifty-nine species of Piper, poplars, willows (sixteen species), walnut and hickory, and alders (six species).

University and Educational Intelligence.

BIRMINGHAM.—At a degree congregation held on July 2 the Chancellor (Lord Robert Cecil) conferred the following degrees:—*D.Sc.*: Fred Johnson; *M.D.*: John Shaw Dunn; *Ph.D.*: H. D. K. Drew, Abd el Rahman El Sawy; *M.Sc.*: F. Adcock, C. F. Allpress, H. Burgess, V. A. Collins, W. A. P. Challenor, J. G. H. Frew, C. V. Hackett, Lucy E. Hardcastle, W. J. Hickinbottom, T. L. Ibbs, D. H. Ingall, F. James, L. A. Jones, E. W. Pratt, E. A. F. Reeve, H. S. Rooke, F. G. Srawley, R. C. Watson, Dorothy Webster, and E. H. Wells.

In addition 134 candidates were admitted to the degree of B.Sc.

The Chancellor announced that the recent appeal had brought in 285,062*l.*, besides increased grants from education committees in the surrounding counties.

A generous donation of 5000*l.* from Mr. C. Hyde has enabled the University to acquire a house, to be converted into a hostel for about seventy men students.

CAMBRIDGE.—A travelling fellowship of 200*l.*, offered to past students of Girton College, and tenable at any foreign or colonial university, has been awarded to Miss M. G. Tomkinson, assistant lecturer in chemistry, Girton College. Miss Tomkinson proposes to work in the chemical laboratory of the University of Toulouse, under the direction of Prof. Sabatier.

DUBLIN.—Mr. D. Clark, lecturer in civil engineering and chief assistant to Prof. Moncur in the Royal Technical College, Glasgow, has been elected to the chair of civil engineering at Trinity College.

The honorary degree of LL.D. has been conferred

upon Sir R. A. Falconer, president of the University of Toronto, and that of D.Sc. upon Prof. E. Borel, of the University of Paris. The ordinary D.Sc. degree has been conferred upon Mr. J. H. J. Poole and Mr. G. de P. Cotter.

Durham.—The honorary degree of D.Sc. has been conferred upon Sir E. H. Tennyson-d'Eyncourt, director of naval construction, the Admiralty.

It is proposed to confer the following honorary degrees on the occasion of the forthcoming meeting of the British Medical Association at Newcastle-upon-Tyne:—*D.C.L.:* Sir William Macewen, Sir Thomas Oliver, and Sir Humphry Davy Rolleston. *D.Hy.:* Mr. T. E. Hill and Dr. J. W. Smith. *D.Sc.:* Sir Arthur Keith. *D.Litt.:* Sir Dawson Williams.

Leeds.—The gas plant specially designed for experimental purposes which Mr. Henry Woodall is erecting as an adjunct to the Department of Coal Gas and Fuel Industries of the University of Leeds, and as a memorial to the late Sir Corbet Woodall, is now in process of construction. Mr. A. G. Glasgow, having expressed his desire to associate himself with this memorial, has made a donation of 500 guineas for the purpose.

Oxford.—Mr. W. C. Burnett, Worcester College, has been appointed secretary of the Delegacy of Local Examinations in succession to the late Mr. H. T. Gerrans.

Mr. P. H. Martin, New College, has been elected to the Theodore Williams scholarship in anatomy, the annual value of which is 50*l.* and tenable for two years.

Mr. A. W. Sheen has been appointed professor of surgery in the Welsh National School of Medicine.

The Joint Committee of the Royal Society and the University of Sheffield has appointed Dr. N. K. Adam to the Sorby research fellowship.

Prof. H. C. Plummer, Royal Astronomer of Ireland, and Andrews professor of astronomy in the University of Dublin, has been appointed professor of mathematics at the Ordnance College, Woolwich.

The London County Council has adopted a recommendation of the Education Committee that the Board of Education and the Senate of the University of London be invited to explore the possibilities of the Holland Park site before further action is taken relating to the Bloomsbury site

Announcement is made of the following gifts:—Bristol University has received from Mr. H. H. Wills the sum of 200,000*l.* to build and equip a new physics laboratory; and Glasgow University and the Royal Technical College, Glasgow, have received 10,000*l.* each under the will of the late W. J. Chrystal, chemical manufacturer.

An election to the Ackroyd memorial research fellowship in the University of Leeds is to be made shortly. The selected candidate will be expected to carry out an approved scientific investigation of a biological, physical, or chemical nature bearing, directly or indirectly, upon the production or properties of wool or other textile materials, or upon the manufacture of textile fabrics. The fellowship is of the annual value of 300*l.* It is tenable for one year, and renewable for a second or third year. Applications must be made to the Registrar of the University by, at latest, July 28.

Calendar of Scientific Pioneers.

July 7, 1854. Georg Simon Ohm died.—The fame of Ohm rests mainly on the small pamphlet, "Die galvanische Kette mathematisch bearbeitet," published by him in 1827, when he was professor of mathematics at the Jesuit College, Cologne. His well-known law was first enunciated a year or two earlier.

July 8, 1784. Torbern Olof Bergmann died.—The contemporary of Scheele, Bergmann from 1767 held the chair of chemistry at Upsala. He made improvements in the methods of chemical analyses, and in 1775 published his essay on "Elective Attractions."

July 9, 1716. Joseph Sauveur died.—The great pioneer worker in acoustics, Sauveur was educated for the Church, but in 1686 became professor of mathematics in the Collège de France. His study of sound covered the last twenty years of his life.

July 9, 1856. Amedeo Avogadro, Conte di Quaregna, died.—Of noble parentage, Avogadro, from 1809 to 1821, was professor of physics and mathematics at Vercelli, where in 1811 and 1814 he published the memoirs containing the law which bears his name.

July 10, 1910. Johann Gottfried Galle died.—When assistant to Encke at Berlin, Galle and D'Arrest, at Leverrier's request, searched for Neptune with the aid of Bremiker's map. Galle first saw the planet on September 23, 1846. Afterwards he was for many years director of the Breslau observatory.

July 11, 1807. George Atwood died.—A distinguished Cambridge mathematician, Atwood first described his well-known machine in 1784 in his treatise on the rectilinear motion and rotation of bodies.

July 11, 1909. Simon Newcomb died.—One of the most distinguished astronomers of recent times, Newcomb, in 1857, at the age of twenty-two, entered the office of the American Nautical Almanac, of which from 1877 to 1897 he was director. Like his colleague Hill, he was a great master of dynamical astronomy.

July 12, 1682. Jean Picard died.—Picard has been called "the father of French astronomy." He was an assistant to Gassendi, visited Tycho Brahe at Hven, edited the "Connaissance des Temps," measured a degree of the meridian, and first used the telescope with the quadrant.

July 12, 1851. Louis Jacques Mandé Daguerre died.—One of the inventors of photography, Daguerre was a successful scene painter, and part owner of a diorama in Paris. Six years after the death of Niepce, with whom he had collaborated, Daguerre, in 1839, obtained sun pictures on silver plates covered with a film of iodide.

July 13, 1762. James Bradley died.—Recognised as one of the greatest astronomers of the first half of the eighteenth century, Bradley became Savilian professor of astronomy in 1721, and in 1742 succeeded Halley as Astronomer Royal. His discovery of aberration was made known in 1729; that of nutation in 1748. His Greenwich observations are of great importance, and were reduced first by Bessel and then by Auwers.

July 13, 1896. Friedrich August Kekulé von Stadonitz died.—The friend of Gerhardt and Williamson, Kekulé was especially known for his speculations on structural chemistry. His work on the benzene theory has been described as "the most brilliant piece of scientific prediction in the whole range of organic chemistry." His statue stands outside the fine chemical institute at Bonn.

E. C. S.

Societies and Academies.

LONDON.

Zoological Society, June 7.—Prof. J. P. Hill, vice-president, in the chair.—Major S. S. **Flower**: Remarks upon *Testudo Leithii* and *T. ibera*.—Dr. P. Chalmers **Mitchell**: Remarks upon a photograph of the death-mask of a young gorilla.—Dr. F. M. **Chapman**: The distribution of bird-life in the Urubamba Valley, Peru.—S. **Maulik**: New Indian Drilid beetles.—Prof. J. P. **Hill**: Some marsupial embryos, especially the koala (Phascolarctos) and the wombat (Phascolomys). —R. I. **Pocock**: The external characters of the koala (Phascolarctos) and some related marsupials.—Dr. C. F. **Sonntag**: The comparative anatomy of the koala (Phascolarctos) and the vulpine phalanger (*Trichosurus vulpecula*).—C. T. **Regan**: The Cichlid fishes of Lake Nyassa.

Royal Meteorological Society, June 15.—Mr. R. H. Hooker, president, in the chair.—G. M. B. **Dobson**: The causes of errors in forecasting pressure gradients and upper winds. The usual method of checking the accuracy of forecasts by finding their absolute error is misleading, particularly when the weather is very settled. It would be better to find the improvement obtained by "forecasting," *e.g.* to compare the absolute error of the forecast, made for twenty-four hours ahead, with the actual change of direction in the twenty-four hours. Trial forecasts of the pressure gradient when checked thus showed but small improvement; the inaccuracy in estimating the future positions of centres of high and low pressure is a large factor, but a greater error is due to the small irregularities of pressure which are local and transitory, and which, therefore, seem almost impossible to forecast.—R. F. **Granger**: The physical structure of cloud form in the lower atmosphere. Beginning with a constructive criticism of the theory of cumulus formation, the behaviour of eddy-formed stratus sheets, the possibility of outward radiation at night, causing cloud formations, and the formation of sub-strata underneath various types of cloud sheet are discussed. The last part of the paper deals with cyclonic nimbus, and describes the cloud structure of a cyclone while rain is falling: that actual rain-producing cloud is formed by the ascent, *en masse*, of the eddy-formed damp layer. A cirrus-like cloud forms at low altitude during the passage of one air current over another if the movement set up by friction causes the elevation of a damp layer in the upper air current. The interpretation of cloud form in terms of physical structure will probably have a place in the weather forecasting of the future.—N. A. **Comissopulos** and J. **Wadsworth**: Variability of temperature over Europe and North America (1900–9). The variability of temperature is measured in this paper by standard deviations from the mean of ten values of the annual mean temperature from 1900 to 1909 for a large number of European and North American stations. The small number of years considered is an objection, but consistent results have been obtained. No correlation is found between altitude and temperature variability, but a fair connection is indicated between latitude and temperature variability. Charts of isopleths representing variability of temperature show generally an increased variability towards the north, but a decrease towards the coasts. Secondary maxima and minima occur, the positions of which follow the configuration of the land in Europe; maxima occur over N.E. Russia, W. Germany, France, and Spain, and minima over the Atlantic and Mediterranean. A chart of S.W. Europe for 1890–99 showed the same general features as that for 1900–9, but with different absolute values for the various isopleths.

Royal Statistical Society, June 21.—Sir R. Henry Rew, president, in the chair.—Mrs. W. J. **Barton**: Women's minimum wages. The main sources of the figures given were the wage rates for unskilled women collected in the *Labour Gazette* and those settled by the Trade Boards. The rates quoted were all minima, and it was difficult to ascertain the proportion of workers earning more than the prescribed rates. The paper dealt with the groups of women workers affected by Trade Board legislation; *e.g.* the distributive trades, sewing trades, laundries, sugar, confectionery, and fruit-preserving trades, paper and printing trades, and the metal trades. Each trade was examined in detail; tables were submitted showing the Trade Board rates payable in different districts and the changes therein at different dates, and where possible the various wages paid by voluntary agreement between employers were given for comparison with the legal rates. Trade Boards had raised the wages of the lowest paid workers, and uncontrolled trades had been strongly influenced, while several trades possessing Trade Boards had agreed upon rates considerably above the legal minimum. A minimum standard wage for the unskilled work of women and girls had been created.

Mineralogical Society, June 21.—Dr. A. E. H. Tutton, past president, in the chair.—Dr. H. **Hilton**: A note on crystal measurement. Labour could be saved by measuring the angles between zones through two faces instead of the angles between zones through one face and the angles between this face and the rest.—A. **Brammall**: The trend of reconstitution processes in shales, slates, and phyllites. The author correlates microscopical data with data deduced from chemical analyses. The finely powdered rock is extracted with (*a*) 20 per cent. of hydrochloric acid, (*b*) 50 per cent. of hydrochloric acid, and the extracts are analysed and discussed with reference to the molecular proportions of the bases present. The residual slime is treated with dilute hydrofluoric acid, freed from silica gel, and thoroughly washed. Free carbon particles are floated off by the froth produced on vigorously shaking up the slime with water to which a few drops of amyl alcohol, paraffin, and sodium silicate have been added. Samples of coarse-grade and fine-grade sericite are separated by elutriation and analysed. Heavy or insoluble residues are obtained and examined. Data referring to Bolivian rocks and the Skiddaw Slate are discussed. The general trend is towards the establishment of a metastable ternary system of white mica, chlorite, and quartz by a process of molecular differentiation: (*a*) Monad-oxides, type R_2O, allied with alumina, silica, and water (mica); (*b*) diad-oxides, type RO, allied with alumina, ferric oxide, silica, and water (chloritic matter); and (*c*) free silica (quartz). In the early stages this differentiation is imperfect: the mica contains iron oxides, magnesia, etc., and the chloritic matter adsorbs alkalis. The identity of mineral species evolving from the chloritic matter depends partly upon the molecular ratio R_2O_3 : RO, and this in turn depends partly upon the reduction of ferric oxide to ferrous oxide. The development of rutile, ilmenite, epidote, etc., is probably subordinate to the main trend.—W. A. **Richardson**: The micropetrography of the rock-gypsum of Nottinghamshire. A wide range of structural types, including many metamorphic types, are found. The evidence supports the view of B. Smith that the main series is of sedimentary origin, and that the nodular deposits are

segregations. The metamorphic effects appear to be due to pressure caused by the partial or complete hydration of the anhydrite.

EDINBURGH.

Royal Society, June 6.—Prof. F. O. Bower, president, in the chair.—By request of the council, Lt.-Col. W. Glen **Liston** gave an address on plague and rats. After a brief historical survey Lt.-Col. Liston traced the course of events by which after the discovery of the bacillus in 1898 the connection between rats and the disease was established. The link connecting the plague in rats with the plague in men had still, however, to be found. A curious experience of a friend who had been attacked by a swarm of cat fleas on entering a part of a house which had been disused for some time suggested the possibility that the rat flea might be the agent of transmission of the disease. Some little time later, in a certain tenement in Bombay, rats began to die from plague, and as the rats became scarce, rat fleas began to trouble the inhabitants, and cases of plague began to develop among them. Lt.-Col. Liston received a sample of thirty fleas caught in these circumstances. Of these fourteen were rat fleas. Previous experience had shown that out of 246 fleas caught on men, only one was a rat flea. Evidently the rat fleas, deprived of their normal host, had fastened on man. Another link in the chain of evidence was provided by an outbreak of plague among some guinea-pigs kept in Victoria Gardens. An examination proved that the guinea-pigs, which normally seldom harbour rat fleas, were infected with many of these, and that plague bacilli were found in the stomachs of some of them. Further experiments were made, and while these were in progress the Plague Research Commission was appointed by an advisory committee of members nominated by the Royal Society of London, the Lister Institute, and the India Office. The findings of this Commission, consisting of Major Lamb, Drs. Rowland and Petrie, and Lt.-Col. Liston, have been universally accepted, proving that rats are the chief cause of plague, and that the plague is transmitted from rat to rat, and from rats to men, through the agency of rat fleas.

June 20.—Prof. F. O. Bower, president, in the chair.—M. M'C. **Fairgrieve**: The annual incidence of intelligence and its measurement by the American Army tests. While many boys of high mental ability have their birthdays in the late spring months, there is a distinct risk that boys born in these months may prove to have intelligence rather below the normal. This result, previously indicated by an application of the Burt tests to a limited number of boys, has been confirmed by the application of an American Army test to as large a number of boys as was available. Norms suitable for the application of the Army tests to other schoolboys are also given, as well as some evidence that the average intelligence of public-school boys increases up to an age of twenty years rather than the earlier limit of eighteen or sixteen years given elsewhere.—J. M. **Wordie**: Shackleton Antarctic Expedition, 1914–17: Geological observations in the Weddell Sea area. (1) A description is given of the ice-bound nature of Coats Land, where there are 250 miles of barrier (shelf-ice) cliffs without bare rocks of any sort. (2) Elephant Island, South Shetlands, consists of metamorphic schists, striking N. 70° E. Mr. Tyrrell examined the rocks petrographically for comparison with other West Antarctic rocks, but found no resemblances; he considers them to have been in part volcanic ashes originally, but now much silicified and chloritised. (3) South Georgia is given a different interpretation from that of Mr. Ferguson. Exception is taken to his attempt at subdividing the rocks and to his interpretation of the structure. Instead of monoclinal folds and block-faulting, one sees extremely complicated folds striking N.W.–S.E. An igneous complex was found at the south-east end of the island. Prof. J. W. Gregory's claim of Palæozoic rocks is not considered proved, a Mesozoic age for the whole series being regarded as much more likely on the fossil evidence. There is nothing to show that an arc comparable with the Antilles connected the islands of West Antarctica. The necessary link, however, between the geologically similar regions of Graham Land and Patagonia may perhaps be found, as Prof. Gregory first suggested, more to the west than South Georgia.—Dr. H. **Levy**: The criterion for stable flow of a fluid in a uniform channel. On experimental grounds O. Reynolds found that a simple critical relation exists between the velocity and the size of the channel and the viscosity of the fluid flowing along it; which corresponds to the passage from steady to turbulent eddying motion. Aero- and hydro-dynamical experiments during the past few years indicate the existence of such a critical relation in general. Many curious aerodynamic phenomena centre round the explanation of this critical state. In the present paper, where the question is regarded from a new point of view, it is shown on general grounds that if a distribution of vorticity is imposed on a viscous fluid, a critical relation should exist between the velocity and size of the boundaries and the strength of the vorticity, separating the stable from the unstable state. The case of a channel along which fluid is flowing with a parabolic distribution in velocity is considered in detail, and the critical relation due to the imposition of a symmetrical pair of vortices deduced and discussed.—Prof. P. **Macnair** and C. M. **Leitch**: The genus Clisiophyllum. The representatives of this genus of fossil corals are exceedingly abundant at certain horizons in the Carboniferous rocks of the West of Scotland, especially in that known as the Blackbyre Limestone. These corals were collected, sectioned, figured, and described by a Glasgow geologist, James Thomson, who created a very large number of new genera and species. The type-specimens were afterwards presented to the Kilmarnock Museum, and were involved in the fire that destroyed that institution. The materials studied by the authors include those specimens that were salvaged from the fire and other collections in which the different genera and species had been named by Thomson. These are now in the Kelvingrove Museum, Glasgow. After the examination of several thousand specimens, nine genera and something like eighty species have been included in the genus Clisiophyllum, four variations of which have been suggested round which the genera may be grouped. Eight of these genera were founded on the axial column, and it is on this structure that the four types of variation depend for their significance. The authors hoped they had shown that these variants are linked together in an ontogenetic sequence, and that this is also a phylogenetic sequence. They believed that the elaboration of species and their supposed values as time-indices, as upheld by the late Dr. Vaughan and his disciples, had been carried to a length wholly unjustified by the available evidence, and urged a return to simpler and more natural methods of stratigraphical and palæontological classification.

PARIS.

Academy of Sciences, June 13.—M. Georges Lemoine in the chair.—G. **Bertrand**: Fredholm equations with principal integrals as used by Cauchy.—H. **Mineur**: Functions admitting a theorem of algebraic addition.—J. **Kampé de Fériet**: Hypercylindrical functions.—

J. **Andrade**: Rolling resistance and optical mirror method.—J. **Le Roux**: The law of gravitation and its consequences. A criticism of the theory of relativity.—A. **Foch**: The phenomena of resonance in aspiration turbines. An indication of the danger of resonance phenomena and of the modifications necessary to avoid them.—M. **Rateau**: Remarks on the preceding communication.—R. **Jarry-Desloges**: Contribution to the study of the bright Martian areas. The observations of G. Fournier at Sétif show that on April 25, 1920, when the white polar cap was at a minimum, the eccentricity was sufficient to leave the pole free from white, but in general the eccentricity is less marked.—J. **Popesco**: The value of the surface tension of mercury in various gases. In a vacuum the surface tension of mercury is constant, and the value found, 44·4 mgr. per mm., agrees with the earlier figure of M. Stöckle. In air, ammonia, and sulphur dioxide the surface tension falls rapidly during the first ten minutes, then more slowly, finally after twenty-four hours reaching a figure lower than in a vacuum. The phenomenon is reversible, since on removing the gas the surface tension recovers its original vacuum figure. The change in the surface tension is probably not due to a chemical action of the gas on the mercury.—P. **Lambert**: The use of polarised light for the examination of old pictures. By the use of polarised light the surface reflections can be suppressed, the colours become brighter and details clearer. The method gives an indication whether a picture can be improved by modifying its varnish.—M. and Mme. E. **Henriot**: The double refraction of compressed glass. It is usually admitted, on the basis of Wertheim's experiments, that the dispersion of the double refraction of compressed glass is negligible. The authors' experiments show that there is dispersion in crown glass, and agree with the values calculated by Havelock's law.—L. **Décombe**: The enunciation of the principle of equivalence in thermodynamics.—G. **Déjardin**: The production of the argon spectra by slow electrons.—P. **Loisel**: Rapid method of measuring natural leakage of an electroscope in view of the estimation of radium emanation.—E. **Darmois**: The molybdomalates of ammonium and sodium. The rotatory power is at a maximum when molybdic anhydride, malic acid, and ammonia are present in the molecular proportions 2 : 1 : 2. Sodium salts give the same ratio.—L. **Meunier** and P. **Caste**: The action of sodium carbonate on solutions of chrome alum.—A. **Portevin** and P. **Chevenard**: The retarded solution and premature precipitation of iron carbide in steels, and the influence of the initial state on these phenomena.—Mlle. J. **Apolit**: The dehydration of phenyldimethyl butanol and diphenyldimethyl propanol.—M. **Pariselle**: The composition of French essence of turpentine; α-pinene bromide. α- and β-Pinene have been isolated from 15 litres of French turpentine by long fractional distillation under reduced pressure; the physical constants have been redetermined, and the action of bromine on the hydrocarbons studied. Even when no hydrobromic acid is evolved, the action of bromine on pinene always gives a complex mixture of substitution and addition products, the hydrobromic acid produced being absorbed by the pinene.—A. **Brochet** and R. **Cornubert**: The tetrahydronaphthols.—G. **Tanret**: The influence of ammonium molybdate on the rotatory power of mannite. A complex compound has been isolated by crystallisation of mannite and ammonium molybdate, and this possesses rotatory power. It is unchanged by water, but immediately decomposed by dilute alkalis into ammonium molybdate and mannite, with loss of the rotatory power.—H. **de Pommereau**: The reduction of ethyl naphthoate and a case of reduction of an alcohol to hydrocarbon by sodium and absolute alcohol. Ethyl naphthoate is reduced by sodium and ethyl alcohol, not to the corresponding alcohol, but to a dihydromethylnaphthalene. α-Naphthyl alcohol is reduced under the same conditions to the same hydrocarbon.—J. F. **Durand**: The decomposition of metallic alcoholates and phenates by heat. Sodium methylate on heating splits up nearly quantitatively into hydrogen, sodium acetylide, sodium carbonate, and carbon. Potassium methylate behaves similarly, and there is evidence that at one stage potassium vapour is present. Sodium ethylate and phenate follow a different reaction.—M. **François**: The stereoscopic photography of crystals.—J. **Bourcart** and R. **Abrard**: Some crystalline rocks of Albania.—L. **Lutaud**: Tectonic observations in the pre-Riffian zone of northern Rharb, Morocco.—L. **Cayeux**: The magnetic iron minerals of the Longwy-Briey basin.—S. **Stefanescu**: The correlation of the alveolar cavities, movements, and structure of the last molars of mastodons and elephants.—A. **Boutaric**: Actinometric and polarimetric measurements at high altitudes. The intensity of the solar radiation received at the surface of the soil, for equal thicknesses of atmosphere, varies in the same sense as the polarisations.—P. **Lesage**: Experimental cultures of *Fegatella conica* and some other Muscineæ.—Mme. E. **Bloch**: Modifications of roots and stems by mechanical action.—L. **Lapicque**: The nutritive exchanges of animals as a function of their body weight.—A. **Thooris**: Contribution to the biological study of divers. A physiological study of two men capable of remaining under water several minutes.—A. **Polack**: The effects of chromatism of the eye in complex colour vision.—L. **Roule**: A new deep-sea fish, *Scombrolabrax heterolepis*, caught near Madeira. A detailed account of a new fish caught at a depth of between 800 and 900 metres.—H. **Hérissey**: The synthetic action of α-methyl-*d*-mannosidase.—E. **Kayser**: The influence of the nitrogenous material elaborated by the Azobacter on the alcohol ferment.—C. **Levaditi**, A. **Marie**, and S. **Nicolau**: The virulence for man of the spirochæta of the spontaneous spirillosis of the rabbit. This organism is not pathogenic for man.

Melbourne.

Royal Society of Victoria, April 14.—Prof. A. J. Ewart, president, in the chair.—F. **Chapman**: The age of the ironstone beds of the Mornington Peninsula. The author collates the previous evidence, based on the fossils, as to the age of the widespread ironstone beds, and by the recent discovery of certain restricted fossils, shows the beds at Landslip Point and Baxter to belong to the Janjukian stage, intermediate between the older, Balcombian, and the younger, Kalimnan. The fossiliferous ironstone from Baxter is a metasomatised polyzoal limestone, the calcareous portion being entirely replaced by limonite.

Cape Town.

Royal Society of South Africa, May 18.—Dr. J. D. F. Gilchrist, president, in the chair.—Sir T. **Muir**: Note on the product of any determinant and its bordered derivative.—P. A. **van der Bijl**: Some South African stereums. South African fungi of the genus Stereum were described.—P. A. **van der Bijl**: A fungus, *Gibbelula Haygarthii*, sp.n., on a spider of the family Lycosidæ. A fungus belonging to the genus Gibbelula, Cavara, found on a spider, belongs to a species hitherto undescribed, and the name *G. Haygarthii* is suggested.—W. A. **Norton**: Circumcision regiments as a native chronology. The Bechuana circumcision regiments show that a military organisation of native tribes based on the successive circumcision companies of the youth was very widespread in South Africa. In the case of the

Baralong and other tribes, the regiment lists, running back to 1750, indicate where the split between different branches occurred. It is sought to carry them far enough back to illustrate the fission of the tribes now distinct from one another, to which tradition points, but the rapid passing of the old people makes this increasingly difficult and urgent. These lists are of value to history and philology, for they aid in dating events.

The London Electricity Inquiry.

THE inquiry into the electric supply for London, which was opened by the Electricity Commissioners on June 14, is still proceeding. Owing to the many conflicting interests of the companies and the local authorities, the question is very complicated; but as there is practical agreement on the engineering side it is hoped that an agreed scheme will be evolved. The Commissioners have to consider six proposals, but only three of them both cover (or nearly cover) the whole area and consider the appointment of a Joint Authority as contemplated by the Electricity Act of 1919. These three proposals were submitted by (1) the London County Council; (2) the conference of local authorities owning electricity undertakings in Greater London; and (3) the London Electricity Joint Committee, 1920, Ltd., which comprises nine of the leading London supply companies. In addition there are also proposals by (4) the Metropolitan Borough Council of Poplar, which asks that the East London supply should be considered as one district; (5) the Great Eastern Railway Co.; and (6) the London, Brighton, and South Coast Railway Co.

The first three proposals have much in common from the engineering point of view. It is recognised that, owing to the financial conditions prevailing at present, the proposals suggested in 1914 for the immediate erection of capital stations would not now be advantageous, although the demand for electric power is much in excess of the supply. At present prices it does not pay to shut down even antiquated stations and to replace them by others more efficient. The L.C.C. scheme (1) is based on the retention and development of certain of the existing stations in the area, whilst the other stations gradually cease to be generating stations. In the original scheme the building of capital stations before 1925 was contemplated, but it is now thought inadvisable to hamper the "Joint Electricity Authority" with a large capital outlay. It is proposed to organise on a sound basis the present facilities in the area. In the first stage of the scheme as now modified eighteen of the existing sixty-one generating stations will be gradually shut down, and in the second stage a further twenty-six will disappear, leaving only seventeen, of which twelve are owned by private companies. In the first stage thirty-one of the stations would be interlinked by high-pressure cables, working pressures of 33,000 and 11,000 volts being used for the interconnecting mains. Considerable economies could thus be effected by diminishing the capital plant required and having engines running only at their most economical load. It will be seen that the proposal is a direct reversal of the earlier electrical legislation, which always contemplated having two competing companies in each district.

After 1925 the L.C.C. contemplates the building of four new capital stations each of 250,000 kilowatt capacity. It also proposes to reconstruct the existing stations at Stepney and Deptford on a much larger scale. All the new stations would be situated on the Thames. The one at Chiswick would be capable of supplying the whole of Middlesex at 33,000 volts. The remaining stations would be east of the Blackwall tunnel at Blackwall, Beckton, and Greenwich respectively. It is calculated that by extending existing stations and interlinking them there will be a total plant capacity of 577,000 kw. available in 1925, and this could supply a demand for 500,000 kw. It is thus possible to postpone the erection of these super-stations in the hope that money and plant will be cheaper after 1925. The maximum power available by extending existing stations is 760,000 kw., but it is probable that in four years' time the gain in lower working costs effected by building these large stations will more than offset the higher capital charges that would have to be met.

The companies (3) desire to restrict the area —at least in the first instance—within a radius of ten miles from St. Paul's. In their opinion it

would not be economical to supply the outlying districts until the demand increases. They differ also from the L.C.C. and the local authorities in the constitution of the "Joint Authority" which they propose. They suggest that it should consist of sixty-two members. As most of the work would have to be delegated to technical committees, we think that a council of this size is much too big and would prove unworkable.

Very divergent opinions are held by some of the County and Borough Councils interested in the schemes. For example, the Middlesex County Council wants to be excluded, while the Surrey County Council, although only part of its territory is involved, wants to be included. The representative of the Poplar Borough Council, which has a scheme (4) of its own, objected to all the first three schemes.

It was pointed out, when the 1919 Electricity Act was passed, that it would be to the mutual advantage of the Joint Authority and the railways that the former should supply electricity to the latter. Some of the railway companies, including (5) and (6), think that they will be able to generate electricity more cheaply themselves, one of the reasons adduced being that the Joint Authority would not be able to borrow money more cheaply than the railway companies can, and would be hampered by having to provide a sinking fund on its capital, no such necessity arising in the case of the railway companies. We think that this is a very doubtful reason. It seems probable, however, that in any agreed scheme consideration of any railway load will be excluded, at least for the first few years.

The brief account given above of the first results of the inquiry will show that the great expectations which some engineers based on the 1919 Electricity Act have still to be realised. Financial considerations and vested interests have proved stumbling-blocks. But it is very satisfactory to note the conciliatory spirit in which the engineers immediately affected by the proposals have considered them.

Supply engineers recognise that fuel economy is the most important problem they have to study. Recent tests show that in the boiler-house it is possible by scientific management to employ usefully from 80 to 85 per cent. of the calorific value of the fuel. It is heart-breaking, therefore, for some engineers to have to use old-fashioned engines which consume 40 to 50 per cent. more steam per horse-power developed than the best modern engines. In the national interest it is necessary that these engines should be scrapped at the earliest possible moment. The great increase in electric power consumption is well exemplified in the case of the city of Sheffield. The 1914 consumption was 20 million units. It is now 172 million units, the coal consumption being 5000 tons per week. In this connection we hope that the use of raw coal for steam-raising will soon be a relic of barbarism. There is no difficulty in designing furnaces for utilising coke, and several are in everyday use. The economies effected by using powdered fuel are also worth considering.

A hopeful sign of the times is the increasing co-operation between the electricity and the gas industries. At the inquiry Mr. G. W. Partridge, giving evidence in support of the companies' scheme (3), said that arrangements had been made with the Gas Light and Coke Co. with regard to leasing part of that company's site at Beckton for erecting a super-station which it was proposed to build in sections as the demand grew. Owing to the large quantity of coke and coke breeze on the site, much of which at present goes abroad, the cost of fuel would be very appreciably cheapened. The gas company would also be willing to let to the companies the use of the existing wharves, piers, railway sidings, etc. There would thus be a great saving in capital outlay. Any of the improvements, which are hopefully looked forward to, in the carbonisation of coal, the utilisation of waste heat, and new by-products would be to the mutual advantage of the two interests.

The history of electric supply in this country is largely one of legislative interference with a flourishing industry. We are glad that the industry is now so largely dependent on private initiative. Engineers have no delusions about receiving large Government grants, although the supply of cheap electric power, bringing new industries to life, is vital to the prosperity of the country. The inquiry has proved that the supply engineers are willing to accept the best and, consequently, the most economical solution, even if at first it affects their private interests adversely.

Congress of Universities.

AT Oxford last week the second congress of the Universities of the Empire was held under perfect conditions as to weather and public and private hospitality. The large and distinguished assembly which forgathered in the examination halls on four successive days was drawn from fifty-nine universities widely

separated geographically, but inspired by the same ideals and working for the same increasing purpose. This number, it may be observed, has not grown markedly since 1912, when the first congress was held in London; but those who were privileged to attend both congresses must have been impressed by the different conditions, moral and economic, which have arisen during the intervening nine years. Lord Rosebery, in his opening address to the first congress, spoke with eloquence and prevision on the throes of travail which the world was at that time undergoing to produce something new to history—"something, perhaps, better than anything we have yet known, which it may take long to perfect or to achieve, but which at any rate means a new evolution." Two years later the thunderclap of war burst over the world. Evolution ceded place to a process more catastrophic in both its physical and its spiritual workings. May it not be said that the universities, stunned and hesitating, are still groping their way in the new world which is in slow and tentative formation?

Assuredly the note of uncertainty was frequently sounded in the papers read at the congress. Prof. Desch, in an address on the place of the humanities in the education of men of science, asserted that scientific education to-day lacked the "synthetic view" which would harmonise the laws of human society and of the physical universe and life. "Science without sociology is imperfect, but with it the artificial division between scientific and humanistic studies disappears." The relation of the universities to secondary education would appear to be a subject upon which definite conclusions should by this time have been reached by those who have applied their minds to the problem. Prof. John Burnet, the distinguished classical scholar of St. Andrews, confessed that his chief qualification to act as spokesman on this question appeared to be that he had failed in rather a conspicuous manner to find a solution which commended itself to anyone in his own country. Universities have been engaged in the training of teachers from their origin, and have for centuries granted to their masters of arts the *jus ubique docendi.* But, as Prof. John Adams pointed out, the principle that all teachers should be trained in universities is not yet established, and there is indeed a dangerous tendency for local authorities to train directly their own teachers within their own areas.

The subject of adult education found eloquent exponents in Lord Haldane, Prof. G. H. Leonard, Sir Michael Sadler, and other speakers; but how vast and inchoate the issues must appear to universities harassed, almost overwhelmed, in the discharge of their immediate obligations! If there is one lesson enforced by the war, it is the danger of neglecting the applications of science. We find ourselves, as Prof. Smithells pointed out in a singularly temperate and closely reasoned address on the universities and technological education, "a people far spent by the cost of victory over a nation of technologists, a nation which had carried to the highest point the training of its people in applying exact science to the mechanical arts of both peace and war." Nevertheless, he was constrained to raise his voice against the unbridled pursuit of applied science and to direct attention to the restraints under which it should be fostered. The Germans, he admitted, among their excesses of regimentation, had good cause to reconsider their educational plan of isolating seminaries of technology. Technological studies must be given their proper place in our universities as a necessary part of the educational organism.

This line of thought was developed also by Sir Robert Falconer, president of Toronto University, who denounced the conception of a university as a set of public utility schools bundled together by the tie of a common administration. A university should be an organism with an intellectual and moral spirit giving it unity and life. The discussion on the nationalisation of universities raised the temperature of the congress by a few degrees. It is noteworthy that the idea of nationalisation has greater terrors at home than in the overseas dominions, some of the representatives of which seem disposed to hug their chains.

We have referred to a few of the questions of university politics and organisation which were discussed at the congress. There are others not less pressing. The relations of the central and local education authorities to university education in this country are still, in a large measure, unsettled. Further, the question of the future supply of university students under existing economic conditions gives cause for grave anxiety. In NATURE for June 30 we published statistics of students receiving university education, which indicated a total full-time student population for the United Kingdom in 1919–20 of 52,600, of whom nearly 17,000 were ex-Service students. Is it not obvious that this *net* total, assuming it will be maintained, is entirely inadequate to meet the future needs of our great and extending Empire?

The question of the establishment of new universities—how many, in what districts, and with what special characteristics—has to be examined. There are also questions relating to the co-ordination of university work with the view of obtaining the maximum benefit from the minimum expenditure, a consideration which in future will be increasingly in the minds of public men and public authorities. We are reluctant to criticise a congress which has been the means of publishing so many useful contributions to educational thought; but it is impossible to overlook the need for a more systematic discussion of these questions of university organisation and for the formulation of guiding principles. As Lord Rosebery insisted at the first congress, every university must work out its own salvation in its own way, and a centralisation of the Universities of the Empire would be demoralising to them and fatal to their growth and development. Acceptance of this general idea should not inhibit an orderly study of various questions of university organisation, the decision of which is already long overdue. If the universities limit their contributions to these discussions to expressions of personal opinion, however adroit and enlightened, the task of finding solutions to these difficult questions will have to be undertaken by some other authority.

A Psychology of Logic.

Psychologie du Raisonnement. By Eugenio Rignano. (Bibliothèque de Philosophie Contemporaine.) Pp. xi + 544. (Paris: Félix Alcan, 1920.) 18 francs.

THE distinguished editor of *Scientia* has given us in this volume a valuable and most useful study, which is likely to take its place as a recognised book of reference. It is original, both in its method and in its subject-matter, to a very high degree, and part of its originality is the way in which it brings together, and works into a complete scheme, the researches and theories based on the researches of experimenters and theorists in all the sciences. The main purpose is to present a psychology of reasoning. By reasoning is meant the higher logical processes of the mind which are distinctive of intellect, and by psychology a descriptive science which interprets a definite domain of reality by bringing it into relation with other domains.

The theory is given in the chapter entitled "Qu'est-ce que le raisonnement?" This appeared as the first of a series of articles in *Scientia* eight or nine years ago, and it forms now a kind of centre or nucleus around which the argument plays. The answer to the question is that reasoning is nothing but a consecutive series of actions or experiments carried out simply imaginatively in thought and not effected materially. The result of the imaginatively represented process is the demonstration or conclusion to which reasoning leads and at which it aims. Reasoning is experimenting internally, thoughts are merely imagined acts.

It will be seen, therefore, that Signor Rignano's psychology moves on the scientific plane and ignores the metaphysical problem. It accepts existence and is unconcerned with the genesis or with the ultimate nature of reality. Given the physical, biological, and physiological basis, psychology can define its data by relation to it. Memory, perception, and productive and reproductive imagination can be described and their function, scope, and limitations determined. The scheme of the work is then clear. A psychology of logic has to show, first, the evolution of reasoning from inferior forms of mind which do not attain to it; secondly, the evolution of reasoning itself into its higher forms; and, finally, the positive factors as they are revealed by the study of abnormality.

On the basis of the assumption that mentality is a phenomenon within the objective world of physical science and presupposes the independent existence of that world, it is undeniable that a great deal of practically useful science can be formulated. The author's numerous, excellently chosen illustrations of the reasoning process are very fascinating. They provide the kind of interest which used to thrill us in the old descriptive "natural histories." Certain doubts as to the soundness of the method, however, very soon invade us. There are extraordinary stories of animal intelligence—all standard illustrations and taken from recognised authorities (Romanes, Jennings, and others), and to be differentiated, therefore, from the tall stories which fill the correspondence columns of some newspapers; but, even so, it is questionable whether they do not darken rather than enlighten judgment as to the mode of working of the animal mind.

To understand the mentality of a dog or of an amœba, surely we ought to study the most ordinary responses and not single out some special case of anthropomorphic behaviour as peculiarly significant. This vice of method spoils a good deal of Signor Rignano's excellent work. For example, take his theory of intuition. In contrast with deductive reasoning, intuition is character-

ised by immediacy. But this immediacy, if we have understood the author correctly, is always relative: the reasoning has been so swift that we have not noticed the stages. Intuition is simply a telescoping of that imaginative experimenting in which all reasoning consists. No one, we venture to suggest, would adopt such a view had he studied instinctive behaviour directly and in its general aspect without attempting to base theories of genesis on specially induced experiments, whether on the infusoria or on the higher vertebrates. The theory may not be wrong, but the method is suspect.

One of the most penetrating and instructive sections is the critical review of the forms of mathematical reasoning. Algebra stands at the top of the scale, logistic at the bottom. The former never parts company completely with the concrete as the latter does. Moreover, logistic stands condemned in our author's view for its utter inability to advance by reasoning to any new fact. Creative imagination is the driving force of reasoning, and this is not only absent from, but also definitely eschewed by, logistic.

Where Signor Rignano will seem to some to fail is in what he denies rather than in what he affirms. The concept when detached from the sensible imagination is for him purely verbal. A concept, self-contained and self-subsistent, a concrete universal, has no place in his theory of reasoning, and in itself is unintelligible. The polemic against metaphysics seems to us the weakest part of his book, and as it is quite unnecessary to his argument its introduction is to be regretted. The metaphysical inquirer is described as one who is determined at all costs to save values. He is moved by affective, and not by intellective, motives. The reply is simply that, as a matter of fact, it is notoriously untrue. The philosopher, as philosopher, is absolutely indifferent to values as values. What impels him to metaphysical inquiry is not desire, or emotion, or affective consideration of any kind; it is the pure need of intellectual satisfaction. Even the author protests that the most "positive" and least metaphysical of inquirers cannot be indifferent to values—why, then, is it presumed to vitiate the motive in one case and not in the other?

Regarded from the author's point of view, as it should be, the book is full of interest, clear and sustained in its argument, and maintained throughout at a high level. We hope there will be a good English translation, for it should prove an excellent text-book for advanced courses.

H. Wildon Carr.

Text-books on Theoretical Chemistry.

(1) *Die chemische Literatur und die Organisation der Wissenschaft.* By W. Ostwald. (*Handbuch der allgemeinen Chemie.* Band 1.) Pp. iv+120. (Leipzig: Akademische Verlagsgesellschaft m.b.H.: Gustav Fock, 1919.)

(2) *The Foundations of Chemical Theory.* By Prof. R. M. Caven. Pp. viii+266. (London: Blackie and Son, Ltd., 1920.) 12*s.* 6*d.* net.

(3) *Inorganic Chemistry.* By E. I. Lewis. Third (revised and enlarged) edition. Pp. xv+443. (Cambridge: At the University Press, 1920.) 9*s.* net.

(1) PROF. OSTWALD'S book constitutes vol. i. of the "Handbuch der allgemeinen Chemie" which he is editing in conjunction with a number of eminent collaborators—Kuenen, Drucker, Marc, Bruni, Dutoit, Cohen, Halban, Bredig, and others—all recognised authorities on the several sections of physical chemistry to which they contribute. This introductory volume is, in effect, a long and discursive essay on the methods of propaganda of science and on the gradual development of the means of disseminating scientific truth. It traces the spread of scientific knowledge through the agency of societies, general and specialised, by means of discussion and publication, by scientific journals, and lastly by treatises, monographs, and text-books. It contains nothing but what is generally known to those familiar with the history of science, but the story is put together with considerable skill, and constitutes an eminently philosophical disquisition on an aspect of that history which has hitherto had few expositors.

Towards the conclusion of his essay Ostwald gives a free rein to his imagination in seeking to forecast the lines upon which the dissemination of scientific knowledge must proceed in the future. He is thus naturally led to what is an obsession with him—the possibility of the universal language—and we are treated to a short *excursus* on the relative merits and disadvantages of Volapük, Esperanto, and Ido. Recent events, for which Prof. Ostwald's own countrymen are wholly responsible, have absolutely shattered whatever hopes he may have entertained of the speedy realisation of his ideals. But, as he says in his preface: "Die Schrift wurde bereits 1914 fertiggestellt und gesetzt: die Ausgabe ist durch den Weltkrieg bisher verzögert worden." To allow the concluding paragraphs to remain unaltered when the work appeared in 1919 is characteristic of German mentality. It requires a very robust faith in the future to believe in their appositeness in present circumstances. We fear that the

probability of the learned author being called upon again to preside over such a gathering in Paris as that which met there in 1907 to discuss the universal language is, to say the least, very remote. Nor have the prospects of German co-operation in the International Association of Chemical Societies, which Prof. Ostwald laboured to found when in Paris, and the Belgian manufacturer, Ernest Solvay, so generously endowed, been rendered any brighter by Prof. Ostwald's subsequent action in connection with the notorious *pronunciamiento* of German "intellectuals," directed against his quondam friends in France and England.

(2) Prof. Caven's book on "The Foundations of Chemical Theory" is an attempt to explain the fundamental conceptions which constitute the basis of the modern theory of chemistry. It is avowedly an introductory text-book, primarily intended for the young student with an elementary knowledge of the science; but it is also hoped that it may be within the compass of the general reader who, in the words of the preface, "wishes to know what modern chemistry really means." We fancy that the general reader who peruses the book will have a rude awakening in that respect. Recent occurrences have led him to believe that modern chemistry is mainly a matter of munitions—high explosives and poison-gases. He will find nothing relating to these subjects in the book, but he will be introduced to such eminently non-militant matters as the atomic and molecular theory, the periodic law, the doctrine of valency, reversible reactions, complex ions, and catalysis. The scope of the book is thus sufficiently indicated. In fourteen chapters distributed over 262 pages the author describes in simple and concise language the main principles and facts upon which theoretical chemistry rests.

The work is well written and forms interesting reading. The judgment of the author is, however, occasionally open to question. There are, for example, two opinions as to the expediency of the standard $O=16$ adopted, largely at the suggestion of the Germans, by the International Committee on Atomic Weights. At the recent conference in Rome it was proposed—and the proposition was favourably received—that the committee should revert to the old standard $H=1$. Prof. Caven expresses the hope that no such modification of the standard will be made. There is no question that any change will lead to confusion, but it is open to doubt whether the consequences will be so serious as Prof. Caven surmises. Even under a constant standard there have been numerous instances of changes in the value of an atomic weight, due, not to the variable standard, but to improvements in the methods of determining the constant. The atomic weight of chlorine, which the author adduces as an instance of confusion due to a changing standard, has been referred to a constant standard for many years past; but the value has suffered a progressive diminution owing to more rigorous experimental inquiries. The same is true of several of the fiduciary values employed in atomic-weight determinations. At the same time, there is much to be said for the retention of the present standard. It is remarkable how many of the atomic-weight values approximate to whole numbers, and are thereby more easily remembered and more convenient in use. The contention of Stas has lost much of its force, since the ratio of H : O is now known to a very high degree of accuracy. The question is certain to be discussed by the reorganised committee in the near future, and it will largely turn on the relative merits of rationalism and expediency, for which the recent re-issue of Lord Morley's "Compromise" may well prepare the members.

For an elementary text-book the work may be said to cover its subject-matter adequately, and it is put together with a due sense of proportion. It is reasonably up-to-date, and, so far as we have been able to discover, it is free from errors. We would, however, point out that Hofmann's name in the table of contents is wrongly spelled, and the mistake is repeated on pp. 27 and 29.

The student who works through this book carefully and intelligently will acquire a considerable stock of chemical facts, and gain a sound knowledge of the generalisations to which they have led.

(3) Mr. Lewis's book on inorganic chemistry, originally published in 1907, is now in its third edition. It is designed for school teaching, and in the preface to the first edition, which is reprinted, the author describes his methods and the plan of his course of lessons. No attempt is made to cover the whole ground of inorganic chemistry; this is not called for where the main object is to teach principles and illustrate them by relevant facts. The plan of the work is original and has evidently been well thought out; for advice concerning it Mr. Lewis was indebted to many Cambridge friends, among them the late Mr. Humphry Jones and the late Mr. F. H. Neville. Mr. Lewis is, indeed, very faithful to his *alma mater,* and he loses no opportunity of acknowledging his gratitude to her and her sons. The lessons are accompanied by carefully chosen experiments, the apparatus for which is illustrated by figures in line drawing.

Each section is followed by "problems," some of which, it must be admitted, are absurdly "academic." Thus, to give the weight of a crucible as 26·59625 grams is what the Germans call "Decimalspielerei," and is apt to convey a perfectly illusory impression of the degree of accuracy attained in an ordinary weighing. The problems should be not so much arithmetical exercises as examples of the principles involved, and to this end it is unnecessary and unwise to inflict upon the student an unwieldy row of decimals which, especially in the hurry of written examinations, may land him into arithmetical blunders and so defeat what should be the real object of the examiner. It is also desirable that foreign proper names should be correctly spelled. The colleague of Dulong in the formulation of the law connecting atomic weight with specific heat is not usually styled Pettit (p. 141), nor, although there are variants in the name, is Ingen Houss (p. 183) commonly so written. Oxygen was discovered by Priestley on August 1, 1774, and not in 1775, as stated on p. 249 and elsewhere. As a matter of fact, Priestley had prepared it from nitre in 1771 without actually recognising it. Scheele, as is now known, was an independent discoverer, and had probably obtained the gas some time prior to 1774; but his first announcement of its existence was made in his treatise on Air and Fire, published in 1777.

Every conscientious teacher, properly equipped with knowledge and experience, and gifted with sympathy and enthusiasm, evolves his own methods of instruction sooner or later; but he can always learn from other teachers, even if at times it is only the negative gain of "how not to do it." From Mr. Lewis his gain will be positive. He will find his system rational and well-ordered, his methods of exposition clear and direct, and his experimental illustrations carefully chosen and strictly to the point.

A Jungle Book.

The Diary of a Sportsman-Naturalist in India. By E. P. Stebbing. Pp. xvi + 298. (London: John Lane; New York: John Lane Co., 1920.) 21*s.* net.

A GREAT part of Mr. Stebbing's book is devoted to the sport and natural history of the big-game jungles of India, and no reader will escape their fascination. They are so primitive, so wild, so full of the unexpected, so tragic in their hidden vestiges of remote civilisation, and withal so rich in possibilities of present-day pleasure—to the sportsman-naturalist especially.

"The log fire burning and crackling merrily outside, the subdued buzz of talk from the servants' lines, the whinnying of the picketed ponies or the shrill voices of the syces raised in execration when a biting or kicking match commences, the dull rumbling of the elephants engaged on their fodder, resembling distant thunder; the great columns of trees forming a background to the camp, on to which the camp-fires cast fitful shadows, whilst overhead the picture is closed in by the blue-black vault picked out with innumerable jewels and spangled with diamond dust. How pleasant it all is. . . ."

Mr. Stebbing tells of his first bull bison (*Bos gaurus*), his first sambhar stag, his first tiger, his first leopard, his first bear, his first boar, not to speak of creatures like pangolins and porcupines which the naturalist enjoyed and the sportsman spared. It is a sanguinary book, but it is very well written, and the tale is adorned with vivid thumbnail sketches by the author and with excellent photographs by Mrs. Stebbing, Mrs. E. M. Sparkes, and Sir John Prescott Hewett.

Mr. Stebbing's general impressions of the jungle are very interesting. One is the warning which the jungle folk pass on when danger is approaching. "This warning, though intended for the friends of the utterer, is understood by the whole community, even though among themselves they may be respectively the oppressor and oppressed." From the moment the tiger or leopard is descried,

"every animal in the jungle is put at once on its guard by the performance of the birds and monkeys. The deer know perfectly well what it portends, and remain on the alert till their enemy has left the neighbourhood. In fact, it is quite common for a tiger or leopard, once he has been discovered in a jungle, to be fairly mobbed out of it; for he knows that once all the jungle animals have been informed of his presence he has a poor chance of getting even a plump young doe to make his meal off."

Another impression is the great difficulty experienced in "picking up" the animals—from elephant to partridge—in their natural surroundings.

"Even a large animal like the tiger can move along in his surroundings in an almost invisible manner. His outline becomes merged in the general colour of the grass or scrub jungle, but there is nothing definite to pick up, and when he is motionless he is almost invisible, if not quite, to the untrained eye. . . . It is usually the eyes of the animal which are first perceived if it is facing the observer. . . . Whilst, therefore, in a new environment and with an untrained eye, the newcomer finds some difficulty in picking out any of the animals in his neighbourhood from their surroundings, the reverse is the case with the jungle

folk. They will hear, smell, and see him seconds, even minutes, before he has any chance of getting on terms with them."

Some people have spoken of the silence of the Indian jungles; but this is true only of the hotter part of the day, when most of the mammals and birds are taking their siesta. In the morning and evening, and at night, the jungles are full of sound.

The interrelations of living creatures are perennially interesting, and Mr. Stebbing gives some fine examples. Thus certain caterpillars, which he names, defoliate great blocks of teak forest, leaving them exposed to the hot sun and hot winds so that the undergrowth becomes scorched and withered. The deer and some other mammals have to quit these shelterless tracts.

"The termite has its uses in the Indian forest, for it rapidly disposes of the vast amount of refuse branches and dead fallen stems which without its aid would accumulate on the forest floor and greatly add to the risk of fires and increase their intensity when they took place, in addition to making progression impossible for man or beast."

The red ants are a source of great trouble to man, though he does make a paste of them which is eaten as a condiment with curry!

"The red ant lives in the trees and builds nests of the leaves. Such nests are a common sight in the sál forests. The nests are constructed in an ingenious manner, the edges of the green leaves being gummed together. The mature ant does not possess any material with which to perform this work. His gum bottle he finds in the immature ant, which has glands secreting a sticky substance. Several of the adult ants hold the leaves together, whilst another seizes a youngster between its mandibles and uses him as the brush of the gum bottle. It shows either a high form of civilisation or a low form of sweating to thus make the children share in the labour of house-building."

The second part of this interesting book deals with the means to be taken to preserve the forest game animals from poachers and unsportsmanlike sportsmen, and this in turn leads to the larger question of the preservation of the Indian land fauna as a whole. Some of the finest game animals are now within measurable distance of extinction, and the creation of game sanctuaries has been commenced with the view of affording protection to certain animals, such as the bison, rhinoceros, and deer. Apart from game, many components of the fauna are of economic value, and zoologically all are interesting. Mr. Stebbing pleads convincingly for large permanent sanctuaries, from which sportsmen, collectors, exploiters, and the like would be barred. One almost feels as if Mr. Stebbing had seen St. Hubert's vision in the course of his book, for he becomes steadily less sanguinary and more of a naturalist. Nevertheless, it is very good reading through and through.

(1) THIS book is in reality sections i.–iv. of the authors' "Geometry: Theoretical and Practical," adapted to the requirements of students preparing for the matriculation and similar examinations. It combines the theoretical with the practical. After an introductory course of practical geometry based on intuition, there follows a series of propositions and theorems amounting, roughly, to "Euclid," Book I., Book III., Book II., and Book IV. The presentation and treatment call for no special comment; they are clear and concise, in the well-known style of the University Tutorial Series. There are many exercises of all kinds and of all grades of difficulty; many of the riders are provided with hints as to which theorems they are based on, and the student is thus led on to discover for himself the best methods for dealing with such exercises.

A few points deserve special mention. The definition of space on p. 34 is not likely to convey anything very clear or even intelligible to the average matriculation candidate. The theorem that the sum of the interior angles of a polygon of n sides is $(2n-4)$ right angles is unnecessarily restricted to convex polygons. Another figure is required on p. 85. Some misprints and one or

two bad diagrams are but minor blemishes on this excellent guide for matriculation candidates.

(2) Mr. Durell's book on the modern geometry of the straight line and circle was intended as a new edition of his "Course of Plane Geometry for Advanced Students, Part I.," published in 1909. There have been, however, such considerable changes that the author has preferred to issue the book under a new name. It contains a pleasant and useful account of the geometry required by scholarship candidates at public and secondary schools, giving the usual work on rectilinear figures, similar figures, harmonic ranges, quadrilaterals and quadrangles, poles and polars, inversion, etc. There is a chapter on vector geometry with statical applications, while in dealing with inversion and coaxial circles the author very wisely makes use of analytical methods and notation. The treatment is sound, and the exercises are numerous.

(3) Many books exist dealing with analytical conics, and presumably every author of such a book aims at making the student interested in this eminently important branch of pure mathematics. Nevertheless, new books on the subject will continue to be scanned with anxiety by teachers of mathematics, because there can be no doubt that many students find the subject difficult, and the existing books scarcely afford them the help they need. One must say at once that Dr. Davison's book is no exception to the rule. It is a clear and sound investigation of the ordinary analytical theory of the straight line, circle, and conic sections, carried out on the orthodox principles and in the orthodox manner. The student who is desirous of learning the subject, and is intellectually and mathematically capable of following the argument, will no doubt study the book with profit, for there are very many examples, revision exercises, and a number of problem papers on the subject. The book is well produced and printed in the clear and interesting style that we have learnt to associate with the Cambridge University Press.

For a possible second edition we would recommend a few corrections and slight additions. In dealing with the distance of a point from a straight line, something should be said about the somewhat difficult question of the sign of the distance. There are *two* tangents to a circle, ellipse or hyperbola, having a given direction. The author assumes that the equation of a circle or conic is of the second degree; this assumption is not good pedagogics in a course of the kind he has produced. Is there any particular reason for putting the equation of an ellipse in the form $b^2x^2+a^2y^2=a^2b^2$? The classical form with a^2, b^2 in the denominators looks simpler and is easier to remember. The director circle of a hyperbola appears to be subject to various vicissitudes, depending upon whether the real axis is greater or less than the imaginary axis; this should be mentioned. There are several misprints; the worst occurs where the co-ordinates of a point on a circle are called $(a \cos \phi, b \sin \phi)$.

(4) "An Algebra for Engineering Students" aims at giving all the knowledge of algebraic principles and processes that engineers should possess before commencing the calculus as applied to engineering. As a particular class of student is catered for, theoretical proof is in places made to give way to illustration and verification, and no one who has any experience of teaching mathematics to engineers will quarrel with the authors on this account. The subject-matter is the ordinary elementary algebra up to and including quadratic equations, and, in addition, indices, surds, logarithms, arithmetical progressions, ratio and variation are dealt with. Graphs and graphical methods are discussed in a competent manner, and the elementary use of the slide rule is explained. A few nomograms are included, but not in such a way as to afford the reader any real insight into their construction or use. The examples are of a practical type, but one cannot help remarking that the worked example on p. 3 is as artificial as any to be found in the "dry" theoretical books.

(5) Dr. Silberstein is an acknowledged exponent of vectorial methods, and anything that he writes on vector algebra bears the stamp of authority. The present book, although intended for optical computers who wish to use vector methods in optical computation, is equally useful to all who wish to read a clear and easy account of the elements of the subject. The ordinary processes of addition and subtraction, and of scalar and vector multiplication, with extensions, are dealt with first; then follows an account of linear vector operators, leading up to dyads and dyadics. Hints on the differentiation of vectors complete a useful little volume. The division of the book into chapters, and the addition of some examples of a practical nature, would increase its value manifold.

(6) Computation and graphical methods of calculation are assuming an increasing importance in mathematical teaching, especially for such students as are preparing to use their mathematics in some industrial or vocational application. Several universities and university colleges have instituted mathematical laboratories, and a book like Dr. Lipka's "Graphical and Mechanical Com-

putation" should be welcome to both students and teachers in such places.

The author has put into book form the course of lectures he has been giving to engineering classes in the mathematical laboratory at the Massachusetts Institute of Technology. It is a comprehensive course, including a discussion of various kinds of scales and the slide rule, networks of scales for several variables, nomographic charts, empirical formulas (with the method of least squares), periodic curves, interpolation, and approximate integration and differentiation (with various kinds of planimeters, integrators, integraphs, etc.). Each part of the subject is dealt with in some detail, with the result that the book is a mine of useful information on practically all the processes that occur in computative or graphical work. One may, perhaps, think that the subject-matter is too condensed both in treatment and in actual print, but as a foundation for a course in a mathematical laboratory the book can be recommended without hesitation; it should find a place in every mathematical and engineering or technical library, and serious students will find it a continual help in their industrial or research work.

A particularly exhaustive treatment from the practical point of view is given of nomography. Perhaps it would be better if the author had laid more stress upon explaining exactly how nomograms are to be constructed and used than upon the reproduction of so many nomograms. This is, however, a matter of taste, and what the author has put into this section of the book is on the same standard of excellence as the remainder. There are numerous examples, many of them worked out numerically in full. The book also contains accurate charts of uniform and logarithmic scales, as well as of square roots.

Our Bookshelf.

Creative Chemistry: Descriptive of Recent Achievements in the Chemical Industries. By Dr. Edwin E. Slosson. (The Century Books of Useful Science.) Pp. xvi+311. (London: University of London Press, Ltd., 1921.) 12*s.* 6*d.* net.

This book is written by an American journalist with some knowledge of chemistry. It is intended for lay readers who wish to make themselves acquainted with some of the recent developments of applied chemistry, including nitrogen fixation, fertilisers, dyes, sugar, rubber, poison gas, and other subjects likely to be of interest to the average reader. The facts, which appear to be accurate and selected with care and discretion, are presented clearly and forcibly, with a certain native humour. Gerhardt should not (p. 6) be described as a German chemist, while the account of the origin of Kekulé's theory of the benzene nucleus (p. 66) differs somewhat from that usually accepted. It is also interesting to know (p. 33) that "we might have expected that the fixation of nitrogen by passing an electrical spark through hot air would have been an American invention [it was discovered by the English chemist Cavendish], since it was Franklin who snatched the lightning from the heavens as well as our sceptre from the tyrant, and since our output of hot air is unequalled by any other nation."

A Little Book on Map Projection. By Mary Adams (Dr. William Garnett). New and revised edition. Pp. viii+112. (London: George Philip and Son, Ltd.; Liverpool: Philip, Son, and Nephew, Ltd., n.d.) 5*s.* 6*d.* net.

The second edition of this useful book differs little from the first, which was published in 1914, but the author's identity is now revealed. Most books on map projection are either severely mathematical or, at the other end of the scale, so trivial as to have little value. Dr. Garnett strikes a happy mean, and contrives to give within a modest compass practically all that a student of geography requires to know of this difficult subject. He wisely takes nothing for granted, and as he develops his subject gives ample explanation at each step. About half the book is concerned with the principles involved, and the remainder with the consideration of the principal projections. The subject is treated with a freshness and lucidity which result in a most readable book. The treatment of Sanson-Flamsteed's, Mollweide's, and Mercator's projections may be specially noted. There are a number of clear diagrams and a short bibliography. The book should make a strong appeal to teachers and students.

Proceedings of the Aristotelian Society. New Series, vol. xx. Containing the papers read before the society during the forty-first session, 1919–20. Pp. iv+314. (London: Williams and Norgate, 1920.) 25*s.* net.

The original papers included in this volume have already been noticed in the reports of society meetings. The present volume contains, in addition to the papers read at the ordinary meetings of the society, two of the symposia contributed to the Oxford Congress last September, in which the members of the French Philosophical Society took part. Of particular interest in this volume is Prof. J. A. Smith's sympathetic account of the philosophy of Giovanni Gentile, an Italian philosopher, the originality of whose speculation, already acknowledged in his own country, is beginning to be recognised universally. We may also mention as of special scientific interest Mr. A. F. Shand's article on "Impulse, Emotion, and Instinct," and Dr. Beatrice Edgell's article on "Memory and Conation." The volume is well up to the high level of the proceedings of previous years.

Letters to the Editor.

The Separation of the Isotopes of Chlorine.

THE method outlined in our letter of September 30, 1920 (NATURE, vol. cvi., p. 144), and used for the partial separation of the isotopes of mercury, has enabled us to accomplish a partial separation of the isotopes of chlorine. When about half of a strong solution of hydrochloric acid cooled down to about $-50°$ C. was evaporated in a high vacuum, the mixture of water and hydrogen chloride being condensed on a surface cooled with liquid air, the condensed part of the hydrochloric acid was found richer, and the remaining part poorer, as regards the lighter constituent of chlorine than the ordinary HCl.

Starting from about 1 litre of 8·6 mol. solution, we obtained, by repeated separations, about 100 c.c. of the lightest, as well as of the heaviest, fraction, the difference of which was examined by two different methods after transforming the acid into sodium chloride. In the first method the density of the two saturated NaCl solutions was determined. The salts were precipitated several times by alcohol from their aqueous solutions, and density measurements carried out after each precipitation. We found uniformly a higher density of the solution prepared from the residual acid, the mean values at 20° C. being

$$d_d = 1{\cdot}20222$$
$$d_r = 1{\cdot}20235$$

from distilled and residual acid respectively. On the assumption of equal atomic volume of the two isotopes these figures correspond to a difference of 0·024 unit in the atomic weight of chlorine, or 6·5 per cent. in the atomic ratio of the isotopes.

In the second method equal quantities (5·7500 g.) of the molten isotopic sodium chlorides were dissolved in water and each precipitated with accurately the same volume of 0·2 n. silver nitrate. The latter was added in a slight excess. After precipitation and dilution to 2000 c.c. the approximate concentration of the filtrate was determined by titration with potassium rhodanide, and the ratio of the silver concentrations of the two solutions measured by combining them to a concentration cell. From the concentration $c = 0{\cdot}00040$ n. and the electromotive force of the cell, 0·0011 volt at 18°, we calculated that the difference in the atomic weight of the two samples was 0·021 unit, in close agreement with the result of the first-mentioned method.

The hydrochloric acid used in these experiments was thoroughly purified with potassium permanganate in order to remove bromine contingently present. Moreover, the repeated precipitation of the sodium chloride by alcohol would have given decreasing values for the estimated separation of the isotopes if any bromine should have been present. We think ourselves justified, therefore, in regarding the above-mentioned results as conclusive.

A Novel Magneto-Optical Effect.

PROF. ELIHU THOMSON's explanation of the interesting magneto-optical effect which he describes in NATURE of June 23, p. 520, is supported by some experiments we have made recently on various oxides dispersed in air. When the vapour of zinc ethyl diluted with carbonic acid gas is mixed rapidly with a large volume of air, a fine fume is produced the particles of which when examined with the ultramicroscope exhibit rapid Brownian motion. In a short time the motion becomes slower and the particles brighter, but fewer in number. This continues until the fume has aggregated into a number of loose complexes formed of irregular chains or strings of particles. These chains are flexible and whirl and twist about under molecular bombardment in a striking manner, but fall under gravity at a surprisingly slow rate. In an electrostatic field the complexes straighten out and arrange themselves parallel to the lines of force, and on reversal of the field rotate through 180°.

When caught on a slide and examined with a high-power objective the same structure is seen more clearly. The individual particles are not in contact, but appear to be held together by invisible threads, consisting probably of strings of molecules or fine molecular aggregates. The zinc oxide fume given off from a zinc arc in air behaves in a precisely similar way. When a dense cloud is produced initially the particles agglomerate to large and irregular masses. By transmitted light the connecting hairs are invisible, but by a strong beam of reflected light of short wave-length obtained by suitable screens the particles appear to be surrounded by a nebulous haze. That the particles in these large complexes are really linked together can be demonstrated in another way by allowing a drop of immersion oil to flow slowly across the slide on which the deposit has been caught; the particles as they are lifted up by surface tension are seen to be attached to constellations of others, and drag these with them from a considerable distance in front of the advancing oil. The individual particles are about $100\mu\mu$ in diameter, and the complexes about 30μ. Even after several hours these clouds always contain a number of single particles.

The particles in clouds obtained by the arc discharge between electrodes of other metals form complexes of varying structure. The tendency to aggregation seems weakest with the oxides of Pb, Cu, Mn, and Cr. It is slightly greater with Fe, whilst the oxides of Mg, Al, and Sb give similar results to zinc oxide. The particles of CdO show a great tendency to aggregate in strings of a remarkable length, which under the microscope look like beads strung on a thread. Clouds of this structure might be expected to show in a strong electrostatic field an optical effect analogous to that described by Prof. Thomson, but so far we have not observed it. The work is being continued.

R. WHYTLAW-GRAY.
J. B. SPEAKMAN.
Eton College, Windsor, July 4.

IN the former account of this novel effect (NATURE, June 23, p. 520) it was pointed out that a microscopic examination of the iron arc smoke deposited on a glass surface gave evidence of the existence of fine particles of iron compound arranged in short chain sections of bead-like relation.

It is now thought that this peculiar formation may have its origin in the outer envelope of the arc flame where the particles are formed and where they are lined up around the arc stream by the circular magnetism surrounding the current conducted by the hot vapour stream of the arc. The particles, being magnetic, would tend to form chains or rings surrounding the arc. These would not be stable, however, but would float away as they became shattered by gas

currents, and remain only as short lengths of particles held together. To throw light on this possibility, a small vertical, hollow cylinder of plaster of Paris open above was arranged with iron electrodes (for forming an arc) passing through its sides and meeting in the centre. By passing the current of a storage battery giving about 50 volts through them in contact and separating them, an iron arc could be produced at will within the plaster cylinder. The dimensions of the cylinder were such that a microscope slide 3 in. by 1 in. could rest across the open upper end of the plaster cylinder, only partly closing it, the slide lying horizontally above the arc electrodes at a distance of about 3 cm. Such a slide could receive a layer of smoke on its under-surface when the arc was formed below it. The microscope in that case showed only a confused deposit.

When, however, there was placed above the slide a strongly excited electromagnet with its poles resting on the upper sides of the slide or close thereto, such poles being about 3 cm. apart, a smoke deposit of a remarkable character was produced. Even as examined by the unaided eye in diffused light there was decided evidence of a structure or striation. When the microscope was used, with even comparatively low powers of about 300–400 diameters, there was disclosed a decided striation seemingly composed of brownish particles in strings extending over the slide and following the direction of the field. There was noted a surprising regularity in the distribution or spacing of the striæ, as if the surface was covered with fibres laid on systematically side by side.

There were, however, curious objects composed of small spheres (evidently globules of iron) strung together in a line of two, three, four, or more, such spheres having no uniform size. Most of these iron globule groups lay, of course, in the field direction, and were very large relatively to the particles in the striation covering most of the surface of the slide. But each of these straight settings of globules possessed a singular appendage, generally at one end only, but sometimes at both ends. It consisted of a brush-like tail composed of the brown filamentous chains of particles like those covering the slide as noted above. They gave the appearance of tufts, suggesting a growth of fine beaded fibres from the end of the string of globules. By focussing, these tufts or tails could be seen as projecting outward (upward) in an inclined direction. This means that the tufts did not lie on the slide surface, but sprang outward from the globule which carried it. The globule at the other end of the short chain (generally the largest in the line) was often to be seen as having a convergence upon it of the usually parallel striæ of the other parts of the slide, indicating clearly that the globules strung together were acting as small magnets with poles at each end, towards and from which poles the convergence and divergence of the magnetic lines were indicated by the fine striæ of particles taking their direction.

The polariscope showed that the striated smoke layer caught on the slide has the same property of scattering or diffusing light (as plane polarised light) that the smoke oriented in the air by a magnetic field has, but, of course, the slide preserves the orientation, and needs, to produce the results, no magnetic field after its formation or deposition. The slide covered with the striated smoke film is, in fact, a polariser.

Examination between crossed Nicol prisms (dark field) discloses the fact that the tufts of fine fibres carried by the rows of globules show as luminous spots on the black field, clearly indicating that the groups or tufts have a polarising effect if they are in proper relation to the rays passing through.

As was to be expected, any hollow vessel or enclosure capable of retaining the smoke from an iron arc can be used in demonstrating the original luminous phenomenon. A glass flask of from 1 to 2 litres is readily sensitised, as it were, by holding its mouth over an iron arc for a short time, allowing smoke from the arc to enter, and then corking the flask. It may then be used to show the effects by allowing a beam of light to traverse it while held in the field of a current-carrying coil. While this was being done it was noticed by Dr. Hollnagel (of the laboratory) that when the coil was traversed by an alternating current of twenty cycles the flask, when near the coil, gave the usual effect of increased luminosity of the smoke in its interior. When, however, the flask was removed from the coil a distance of several feet the steady luminosity was replaced by a flickering which kept pace, not with the alternations of current in the coil, but with the cycles only. The flickering was, as it appeared, at the cyclic rate. This flickering was noted even at a distance of 12 ft. from the coil, although the coil was but 7 in. in diameter and about 2 in. in axial direction. The flickering is a curious effect, and it is difficult to explain, especially the fact that it appears to keep time with the cycles, and not with the alternations, of current. It points to some sort of magnetic retention or polarisation of the iron particles of the smoke. They may even rotate or oscillate in obedience to the field fluctuations, but there is needed much more work of investigation as to the cause of the peculiar behaviour. The experiment clearly shows that a very moderate field intensity suffices for lining up the particles in the air, and so producing the luminous effect.

Emphasis is again given to the fact of the extremely small amount of iron particles suspended in the air capable of giving a decided effect.

ELIHU THOMSON.

Thomson Laboratory, Lynn, Mass., June 17.

The Japanese Artificially Induced Pearl.

THE subject of artificial pearl induction, I venture to suggest, affords an excellent example of comparative pathology. Dr. Lyster Jameson's diagram in NATURE of May 26, p. 396, might well pass as an illustration of "pearls" frequently found in the human body. Such "pearls" are commonly seen in papillomata of the skin and at muco-cutaneous areas, but they can also be demonstrated in the tonsils, brain-coverings, thymus and thyroid glands, etc. Those which are epidermal become keratinoid, but others of deeper origin are often calcified.

All "pearls," whether ostreal or human, start in columnar cells and undergo metaplastic changes. Those of a wart become horny; those of the oyster calcified. The histological changes in the oyster are simply a matter of degree, and not difference.

The diagram fully illustrates this. The "blister" if seen in horizontal (transverse) section would present the same features as seen in the "pearl"—a concentrically laminated core surrounded by a single layer of cubical cells, embedded in mesoblast if growing, but when growth stops the cubical layer would be no longer seen.

"Islands" or "rests" of epithelial elements are common in man. In the oyster such an inclusion may become the true pearl and grow like a wart. Artificial induction or grafting merely imitates the natural process, and its later history is simply a matter of slight change in degree. In either case the pearl must be viewed as a morbid structure due to focal irritation. It is held that a wart may become malignant. In

other words, it may grow too fast and eventually kill the host.

Do the pearl elements ever behave so in the induced variety?[1] Should any positive evidence of this be available, it would throw much valuable light upon the ontogeny of cancer.

The view that warts, and even cancers, are transplantable is strongly supported by the artificial induction of pearls.

WYATT WINGRAVE,
Consulting Pathologist, Central London Throat and Ear Hospital.
Lyme Regis, Dorset, July 8.

I DIRECTED attention in my 1902 paper (Proc. Zool. Soc., March 4, 1902) to the resemblance between pearls and "the structures sometimes found in epidermoid tumours and atheroma cysts." A pearl might be compared to the concentrically deposited ball of desquamated epithelial cells characteristic, I believe, of the latter, except for the fact that the pearl (like the normal molluscan shell-substance, and unlike the outer layer of the skin, and the nails, horns, hair, etc.,

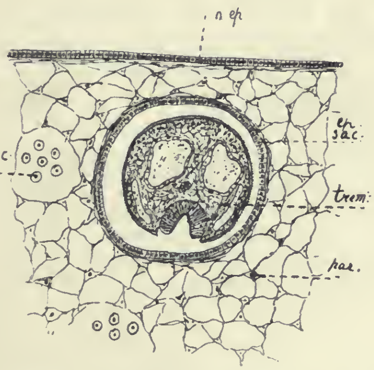

FIG. 1.—The pearl-inducing trematode *Gymnophallus dapsilis* or *G. bursicola* in the sub-epidermal connective tissue of Mytilus, surrounded by an epidermal sac which becomes the pearl-sac: *o. ep.*, outer shell-secreting epidermis; *ep. sac.*, epidermal pearl-sac; *par.*, parenchymatous connective tissue; *bl. c.*, blood-cells; *trem.*, trematode. The sac is usually about 0·4 to 0·5 mm. in diameter.

in mammals) is not composed of cells, but secreted at the surface of cells.

I cannot agree that the difference between a blister and a pearl is one of degree and not of kind, as Dr. Wingrave seems to suggest; in spite of the fact that the nature of the secreting cells, and of the substance they secrete, is identical. The blister is the normal response of the outer shell-secreting epidermis to the mechanical stimulation of any body that comes in contact with it. In this sense it resembles a corn on the human foot, or the thickenings of the skin on a navvy's hands. On the other hand, recent evidence goes to show that the sac, or "island," of epidermis in which the pearl is formed arises only in certain quite *specific* circumstances. In the case of the edible mussel the "circumstance" is probably the specific stimulation (quite likely of a chemical nature) of the trematode *Gymnophallus dapsilis* or *G. bursicola*. These worms normally become surrounded by such a sac in Mytilus (Fig. 1), and when the worm dies, or leaves the sac, a pearl is formed in it. A smaller trematode, which I have not identified, also occurs in the sub-epidermal connective tissue of the mussel; but this species, which is surrounded by a cyst, probably secreted by the worm itself (Fig. 2), and not by an epidermal sac, does not, in my experience, give rise to pearls. Similarly the cestode larva (*Tylocephalum ludificans*), which was wrongly identified by Herdman, Shipley, and Hornell as concerned with pearl formation in the Ceylon pearl oyster, is surrounded by the oyster with a fibrous con-

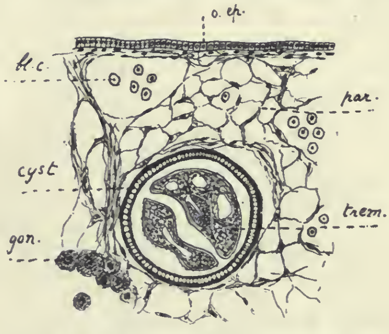

FIG. 2.—A smaller (unidentified) trematode in the sub-epidermal connective tissue of Mytilus which is surrounded by a cyst, probably secreted by the worm itself. The mollusc does not surround the worm with an epidermal sac, and there is no evidence that this species of trematode ever becomes the centre of a pearl: *gon.*, gonad. Other letters as in Fig. 1. The cyst is about 0·15 mm. in diameter.

nective tissue capsule (Fig. 3), and does not appear to possess the power of provoking the mollusc to produce the epidermal sac in which alone a pearl can be formed.

In the case of the Mikimoto pearls and of the pearls artificially produced by Alverdes, the special "circumstance" is the performance of a particular transplantation of tissue.

One of the facts which have favoured the survival

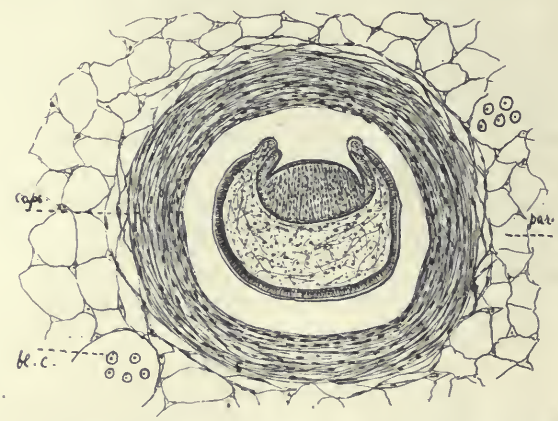

FIG. 3.—Solex of the cestode *Tylocephalum ludificans* in the connective tissue of the Ceylon pearl oyster. The mollusc surrounds this worm with a capsule (*caps.*) of fibrous connective tissue instead of with an epidermal sac. In spite of statements to the contrary, no satisfactory evidence has been adduced that this worm is associated with pearl formation. Letters as in Fig. 1. The entire capsule may measure as much as 2 or 3 mm. in diameter.

of the theory that the same kind of mechanical stimulation that produces a blister can produce a pearl-sac and a pearl is the occasional presence in fine pearls of grains of sand and other foreign bodies. I recorded and figured several such instances, from Ceylon pearls, in my 1912 paper (Proc. Zool. Soc., 1912, pl. xlii., Fig. 38; pl. xliii., Figs. 44, 45; pl. xlv., Figs. 54, 54*a*; pl. xlvi., Figs. 55, 56). I suggest the following possible explana-

[1] The step from a "pearly" wart to a "pearly" or nested epithelioma is a very short one.

tion of the presence of these bodies. One or two writers have recorded the occurrence of sacs with watery contents in different molluscs. The most notable instance known to me is that of *Modiola modiolus*, which, in the Barrow Channel, opposite the Lancashire and Western Sea Fisheries Laboratory at Piel, frequently contains leathery periostracum pearls in the mantle margin, and, associated with these, cysts lined with epidermis, containing watery or mucoid matter. In one of these cysts, some twenty years ago, I found what appeared to be the spores of a protozoon of some kind, but I have not been able to repeat this observation. If sacs of this kind, whether of parasitic origin or due to some pathological condition of the oyster not of parasitic origin, occurred in the Ceylon pearl oyster, and either occasionally burst or normally dehisced to liberate a parasite or its spores, such bodies as small grains of sand, or (as in one of the pearls figured by me) a small quantity of mud containing diatoms, etc., might sometimes be swept into the sacs by the ciliary current and become the "nuclei" of pearls.

The distribution of pearl-producing examples of the various species of molluscs points to the conclusion that the presence of pearls—in other words, the development in the tissues of the mollusc of pearl-sacs—is associated either with parasites which are peculiar to certain localities, or with pathological conditions, following upon particular environmental conditions, which are strictly local in their occurrence. Thus the Ceylon pearl oyster, which produces pearls abundantly in the Gulf of Manar, rarely produces them in Trincomalee Harbour, while the distribution of pearl-producing beds of *Margaritifera maxima* and *M. margaritifera* is still more striking. We find the same local distribution of pearl-producing individuals in the fresh-water pearl mussel Margaritana, and more noticeably in Anodonta.

Personally I am inclined to anticipate that in many of these cases pearl formation will yet be shown to be associated with unicellular parasites. But, whether the pearl-sac is of parasitic origin, or due to some obscure response of the mollusc to a particular set of environmental conditions, it might well prove a highly profitable enterprise to transplant young examples, particularly of such species as *Margaritifera maxima* and *M. margaritifera* from beds where the percentage of pearl production is low, or where pearls are never produced, to some of those beds where almost every individual contains pearls. This process, if successful, would bring the production of pearls into line with the relaying of edible oysters on grounds where the conditions are such as to secure that they will fatten properly for market.

H. LYSTER JAMESON.

Sources and Sinks.

MR. DUFTON's experiment (NATURE, June 23, p. 522) showing attraction between a source and an equal sink illustrates forcibly a remark by Mr. A. Mallock in the issue for August 19, 1920, p. 777: "In most problems relating to the actual phenomena exhibited by fluids in motion, the simple assumptions on which the hydrodynamical theory of text-books rests are insufficient, and experiments are required." At my suggestion Mr. R. Schlapp has recently been making some experiments on the forces between sources and sinks. The vertical limb (about 80 cm. in length) of a **T**-shaped glass tube dipped into a tank of water, and the horizontal portion rested on **V** supports. One end of this horizontal part was sealed, the other was connected by rubber tubing either to a high-pressure water supply or to a water pump, so that the end of the tube in the tank acted as either a source or a sink. Three types of orifice were used: (*a*) the open end of the glass tube (internal diameter 0·4 cm.)—this worked well as a sink, but was unsatisfactory as a source; (*b*) a hollow brass sphere (diameter 2 cm.) with numerous perforations; (*c*) a short length of rubber tube having the lower end plugged and perforations over about 2 cm. On the whole the last arrangement proved the most convenient, but care had to be taken to ensure that no movement arising from lack of symmetry in the size and spacing of the perforations took place when using an isolated source.

When a single source was in the neighbourhood of a fixed vertical wall, attraction was observed. The attraction was very distinct at small distances, even with a small flow of water. At greater distances and with a stronger source the motion was irregular. Attraction was found also between a sink and a wall.

When two sources were employed it appeared as if they were under the influence of two forces, one attractive and the other repulsive, the former being predominant at distances less than about 2 cm. At such small distances the sources were drawn together and remained in contact as long as the water flowed. Additional evidence for the existence of a repulsive force was afforded by the observation that a fixed source repelled a second tube through which no water was flowing with a force which was greater or less according as the flow of water was large or small; but at small distances the action was attractive. Two sinks attracted one another, no repulsive tendency being observed.

Although Mr. Dufton's experiment showing apparent attraction between a source and a sink in a Winchester bottle was repeated successfully, experiments in an open tank, using the perforated rubber tube as a source and a similar arrangement or an open tube as a sink, showed strong repulsion between source and sink.

It is, of course, obvious that the conditions in such experiments differ in several respects from those assumed in the hydrodynamical theory of sources and sinks in an infinite mass of fluid. H. S. ALLEN.

Helicopters.

MR. MALLOCK, in his letter in NATURE of June 30, p. 553, omits the chief reasons for the non-success of helicopters so far.

The first and, to the engineer, most obvious difficulty is the extra weight of moving as compared with fixed wings, and this applies to ornithopters equally.

The second, demonstrated conclusively by Riabouchinsky at the Koutchino laboratory in 1909, and recently rediscovered by ourselves, lies in the phenomenon of mutual and self-interference of the blades of an airscrew, now commonly called the cascade effect.

Each blade blows down the next following in the spiral path, then the other blades in turn, then again itself and the others, the effect becoming fainter as the axial distance from the "image" of itself and the others becomes greater.

In aeroplanes and helicopters, as in all structures which are kept geometrically similar, the weight increases as the cube and the lifting surface as the square of the typical dimension, and though some fining down of large structures can be made in comparison with small, this physical law limits the size alike of the vulture, the elephant, the whale, and the aeroplane. In helicopters the limit comes sooner than in the aeroplane, for the two reasons given above.

If this fundamental relation is ignored, the aeroplane or helicopter will be fortunate if it meets no

worse fate than the ostrich, and merely fails to leave the ground. A. R. Low.

A Prehistoric Cooking-place in Norfolk.

Collectors of Stone-age implements are well acquainted with the calcined flints known as pot-boilers, which are found sparsely strewn over the sites of most prehistoric settlements. As the sun-baked pottery of the kitchen utensil would not stand the fire, heated flints were thrown into the vessel to bring the water to the boil.

My attention having been directed by Mr. Baldry, of Cranwich, to a mound in Buckenham Tofts Park, Norfolk, where the moles were throwing out a remarkable number of these pot-boilers, with the kind permission of the owner, Mr. Underdown, I started excavations on the spot in May last with the view of discovering their origin.

Owing to numerous springs taking their rise at a somewhat high level in the park, the old chalk land surface has been carved out by water action into a series of large natural folds, which at first sight might appear artificial. On one of these, where the burnt stones are found in great profusion, we commenced operations, running a trench from the west side up the slope, a distance of 66 ft., and another near the starting-point at right angles to it. About 8 ft. from the base of the fold, and in close proximity to a stream, on removing about 3 in. of surface-grass and mould, we at once came upon a compact mass of pot-boilers. These continued to a depth of 2½ ft., resting upon blackened earth, which when dug through was found to be lying on the chalk. Tracing the calcined stones from the base of the mound upwards, many thousands came to light, ever decreasing in numbers as they approached the summit, as though thrown out from the spot on which they had been used.

The finding of remains of what appeared to be a great communal kitchen was extremely puzzling, and only when I got into communication with Mr. Cantrill, of the Jermyn Street Museum, did a possible clue present itself. Mr. Cantrill had published in *Arch. Cambrensis* accounts of his investigations of similar stone-boiling sites in Wales. His papers also refer to quite a number of these prehistoric cooking-places, known as "deer roasts" or "giants' cinders," in Ireland, and I am now informed by Mr. Crawford that they are not unknown in Scotland. In England, Mr. Cantrill tells me, they have never yet been examined.

These accumulations are supposed to have been the large cooking-hearths where the flesh of the red deer or other big game was boiled. The finding of hollowed tree-trunks in some of these mounds in Ireland suggests that a trough of this kind was sometimes used to contain the water. Mr. Cantrill suggests that another alternative would have been to dig a hole in the chalk and line it with a raw hide to serve as a cooking vessel. To boil such a great amount of water heated stones in large quantities would have been ladled into the vessel.

So far no satisfactory evidence as to the date of these places appears to have been forthcoming. A general opinion, however, seems to prevail that they are of Neolithic origin. This view may be substantiated by our finding among the pot-boilers quite a number of humanly struck flint flakes showing bulbs of percussion. Still more interesting was the discovery of what appears to have been a small circular pit dwelling within a few yards of the heap of pot-boilers. It measured 11 ft. in diameter. Opening this out, we came upon a hearth of quite normal appearance—flints reddened by the fire, with a few pot-boilers strewn about, and an area of blackened earth. Here it was evident that some individual had sat and fashioned his flint tools, for flakes lay about in profusion, with spalls and a fine core. A scraper of unusual form, but strongly reminiscent of some of those found at Whitepark Bay, in Ireland, lay among flint knives and other small tools, while an arrow-point, worked on both sides and with one barb already punched out, may possibly by its workmanship give the required date to these mysterious sites. Further examination of the Buckenham Tofts mound will, it is hoped, be made in the near future under the auspices of the Percy Sladen Trust.

Nina F. Layard.

Science and Civilisation.

May I venture, as a citizen, to make an appeal to men of science and to urge that the time has come when they should no longer stand aside from the social and political questions that vex the world? Science is itself dependent upon favourable social conditions: that these conditions can abruptly cease has been clearly shown in the case of Russia. Scientific workers have therefore the strongest class interest in the social conditions under which they live. They have, however, more than a class interest. Science has made civilisation possible for mankind. It must now provide civilisation with that authority the lack of which is causing such waste of human energy to-day. Men of science alone have the power; they alone are above suspicion.

This is no place for details. An international amalgamation of existing scientific organisations would provide the world with an intellectual aristocracy, independent of the vote, which by the development of knowledge and the control of new weapons, lethal and industrial, would soon acquire the necessary influence. B. J. Marden.

Stodham Park, Liss, Hampshire, June 30.

Measurement of Small Inductance.

The method of suspending a loop of wire in a uniform alternating magnetic field, as used by Fleming and Elihu Thomson for the construction of A.C. galvanometers, can be applied with advantage to determine the self-inductance of loops in absolute measure, and it would seem that we can go considerably lower in this way than can conveniently be done otherwise. Low-frequency measurements are inaccurate, but with a triode at wireless frequencies I have measured inductances from 20 cm. to 50,000 cm. with an average error of 1½ per cent. without special precautions to obtain sensitiveness. The details of the experiment will appear shortly in the *Philosophical Magazine*. F. B. Pidduck.

Queen's College, Oxford, July 2.

A New Acoustical Phenomenon.

The phenomenon described by Dr. Erskine-Murray in a letter under the above heading in Nature of June 16 (p. 490) is particularly well heard when one is standing near a cliff or rock-face and listening to the sound of a waterfall or of the waves breaking on the seashore. The phenomenon is, of course, familiar to physicists, but it may not be so well known that use can be, and indeed often is, made of this effect in avoiding obstacles when one is walking in the dark. No doubt blind men, consciously or unconsciously, use it in this way; and it must have been so used from remotest antiquity by man and any other animals which happened to have the necessary discriminating power in hearing. G. A. Shakespear.

The University, Birmingham, July 8.

Large-scale Chemistry at the Imperial College of Science and Technology.

IT is now generally recognised that a student in chemistry who wishes to rise to any position of prominence in his profession, either in the industry or in academic life, must first obtain a thorough grounding in his subject by passing through a recognised honours school, and that he must then devote one or two years to training in the methods of research. It is usually during the third year of his honours course that the student first comes in contact with the realities of organic chemistry, and a considerable portion of his time during this period is devoted to a series of preparations in the organic laboratory. The organic laboratory is generally fitted with every type of glass and porcelain apparatus necessary for the student's needs, and he learns here the usual operations and requirements involved in the preparation of a number of typical organic substances. This training is undoubtedly of the greatest value, yet, because someone at some time ordained that there should be two kinds of chemistry, namely, that carried out in glass vessels and that effected in vessels of metal, the unfortunate student, who must needs satisfy a board of examiners who have passed through the same course as he, is instructed in the former kind of chemistry, and left either to imagine the fundamental conditions underlying the latter kind or to learn them in sorrow and tribulation under the more exacting conditions of the factory.

Owing possibly to his early training as an engineer, the present writer has always felt acutely the anomaly of this position, and has sought for an opportunity to erect a laboratory which should contain, like the ordinary small-scale laboratory, types of appliances suitable for all purposes—reduced replicas of those used on the industrial scale, but sufficiently large to render the usual industrial operations essential. This opportunity has now arisen owing to the generosity of an old student of the Imperial College of Science and Technology, Mr. W. G. Whiffen.

A laboratory of this kind will serve several purposes. It will, for example, enable the student, and especially the research student, to familiarise himself with operations carried out in vessels into which he cannot see and the contents of which he cannot transport by hand. He will become acquainted with factors, such as heat transference, cost of production, etc., fundamental in large-scale work, but which are of minor importance in ordinary laboratory practice and usually ignored. He will learn, moreover, in the small fitting-shop attached to the laboratory how to make the necessary metal connections and to erect plant of metal in the same way as he is taught to build up apparatus of glass in the small-scale laboratory. Knowledge of this kind cannot fail to be of the greatest service both to students intending to enter industry and to those who have decided to follow an academic life. Indeed, the laboratory is not a "technical laboratory" in the strict sense of this much misused term, but rather the logical outcome of any adequate system of training in chemistry, and ought, therefore, to find a place in the equipment of every chemical school of university standing.

Again, the advantage to the research student will be very great, because he will be able to prepare his initial material on the large scale, and it will be possible for him to carry out, if necessary, any new preparation which he may have discovered on a scale approaching that required for its commercial production.

FIG. 1.—Staging showing filter presses and mixing tubs.

Two questions have frequently been asked, namely: (1) How will it be possible to initiate a large number of students into operations such as those which it is proposed to carry out in this laboratory? and (2) How can the material prepared be disposed of? The answer to the first question is that the third-year students will work in batches of six or eight under the direction of one student as foreman, and, of course, under the general control of the demonstrator in charge of the laboratory. Each batch will carry through one complete preparation, say nitrobenzene—aniline—acetanilide—*p*-nitroacetanilide—*p*-nitrophenol, and will obtain the pure product. It will be possible,

if necessary, for five or six such batches to work at the same time, and it can be arranged that students from the main laboratory will, during their organic course, pass for a week at a time into the larger-scale laboratory.

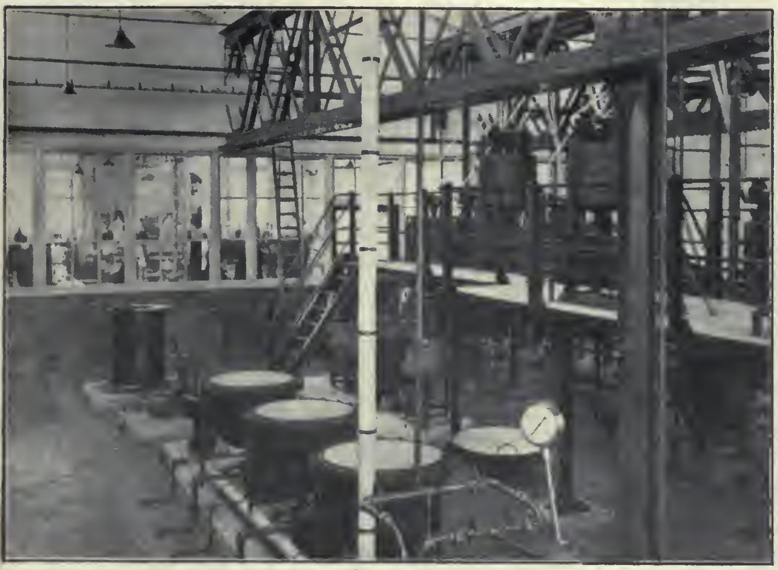

FIG. 2.—View towards S.E. showing evaporating pans, centrifuges, and box filters. Research laboratory through screen.

Regarding the second question, the operations carried out will lead to the production of material which can not only be used for further work on the intermediate scale, but will also be utilised in the small-scale laboratory for the ordinary students' preparations. It is more, however, in connection with the preparation of initial material for research that the new laboratory will be of the greatest service from both instructional and utilitarian points of view. No one who has conducted a school of research containing twenty or more research students can have failed to realise the waste of time entailed by having to go back to the beginning every time the supply of material is exhausted. It is evident that much time will be saved if large quantities of the initial material can be prepared as soon as the conditions for its preparation have been ascertained. The general design of the laboratory has been worked out in conjunction with the late Dr. J. C. Cain, after consultation with Mr. F. H. Carr, then in charge of Messrs. Boot's research laboratories at Nottingham. The general erection of the plant has been due to the skill and interest of Mr. James Robinson, of Messrs. Mather and Platt, Ltd.

Description of the Laboratory.

The laboratory occupies a floor-space 50 ft. by 47 ft., exclusive of the adjoining fitting-shop and research laboratory. It is 22 ft. high, and is covered by an asphalted ferro-concrete roof arranged for semi-indirect north lighting, the light being transmitted through safety (armoured) glass and reflected from the white ceilings and from the white glazed surface of the walls. The advantages of this type of lighting are well known, and in the present instance the success of the arrangement is complete, a clear, steady light being obtained throughout the day. The floor is water-tight and acid-proof. It is paved with red tiles laid in such a way as to shed into the two main drains (Figs. 1 and 2), which run parallel to each other throughout the length of the room. With this arrangement—a most necessary one in a laboratory of this kind—it is a simple matter to give the floor a wholesale wash-down with fire-hoses, six of which are situated at various convenient points.

The centre of the laboratory is occupied by a platform (Figs. 1 and 2), approximately 6 ft. by 40 ft., supported on stanchions 5 ft. above the floor. On and above this, fixed on suitable steel structures, are types of apparatus, such as open-top tubs, which, in general, are most conveniently emptied through a bottom run-off by gravity.

All fixed chemical apparatus, except that on the central platform, is set in concrete foundations carried to a height of 6 in. above the floor-level, whilst the motor, air compressor, and vacuum pumps are bedded in concrete blocks raised to 15–18 in. above the floor.

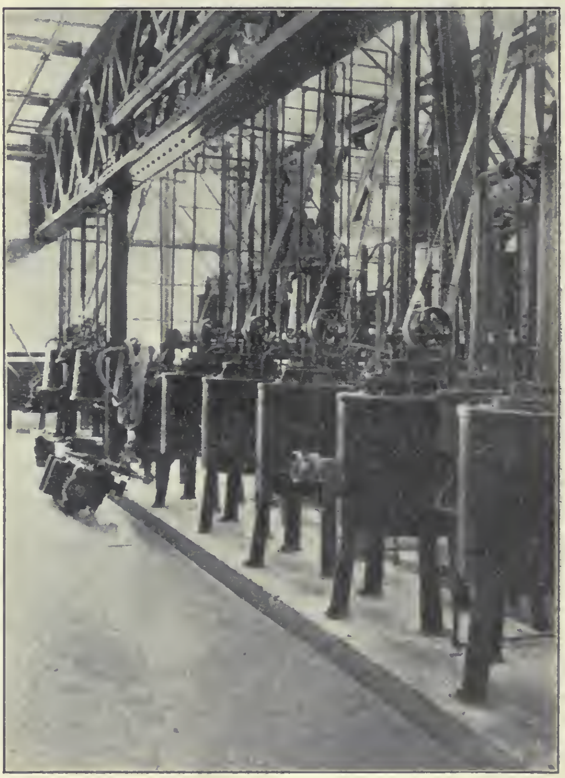

FIG. 3.—Series of general reaction pots.

The power for stirring, air compression, etc., is obtained from a 15-b.h.p. totally enclosed and ven-

tilated acid-proof motor, and is transmitted by two parallel lines of shafting hung in ball-bearings along the whole length of the laboratory and in the fitting-

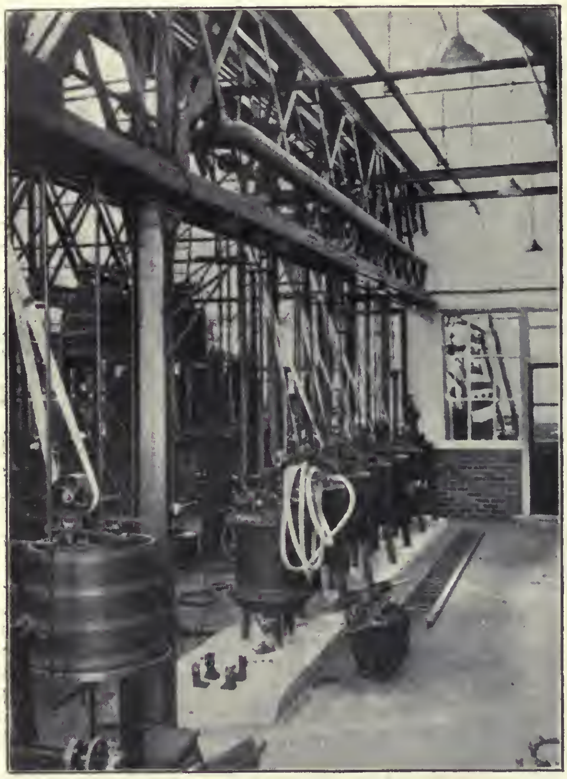

FIG. 4.—View showing distribution of high- and low-pressure air, hot and cold water, steam, vacuum, and gas services, with fitting-shop at back.

shop beyond. Resting on the shaft-brackets are the main pipes (showing through the lattice girder in Fig. 4) of the seven principal services :—Steam, 80-lb. air, 10-lb. air, vacuum, hot and cold water, and gas.

Both high- and low-pressure air are obtained from the same compressor (Fig. 5), which, by an appropriate arrangement of blow-off and reducing valves, delivers into two separate receivers at the required pressures. From these the air is led through high- and low-pressure mains to all parts of the laboratory, the former main being in permanent connection with the mild steel (lead lines) liquor receivers from which the filter-presses are charged, and the latter with most of the other apparatus in the laboratory; for it is the low-pressure air which is put to such general uses as blowing liquor from one vessel to another, stirring where mechanical stirring is inconvenient, blowpipe work, and so on.

The main vacuum pump (Fig. 5, at back), which exhausts a 40-gallon vacuum chamber to the vapour tension of water in about two minutes, is used not only for "sucking" the contents of open-top vessels into the liquor tanks, but also for vacuum distillation and for exhausting the vacuum drying ovens, which, however, are connected in addition to a small pump capable of maintaining a vacuum, once established in the ovens, for any length of time.

Steam, gas, and cold water enter the laboratory from without. Hot water is obtained by passing water and steam through Mather and Platt unit heaters, which raise the water to the boiling point as quickly as the pressure in the mains is able to force it through the delivery pipes.

The types of apparatus permanently fixed in the laboratory are intended to render possible on the greater scale all ordinary chemical operations. The digestors, for example (Figs. 3 and 4), include vessels suitable for nitration, sulphonation, fusion with alkalis, acid and alkaline reduction, acid and alkaline hydrolysis, esterification—in fact, almost every operation which in an ordinary laboratory one associates with a flask on a sand-bath. Heating under pressure is performed in gas-fired heavy mild steel autoclaves. The stills include an apparatus for distillation in a current of saturated or superheated steam, a gas-fired still with a Young's column, a vacuum still with an arrangement of receivers equivalent in its use to the Perkin triangle, and a pan for vacuum evaporation. The redwood tubs on the platform are fitted with stirring gear, and arranged suitably for such operations as diazotisation and coupling and for washing solid precipitates and oils; they are the beakers and separating funnels of the laboratory. Apparatus for the three chief methods of filtration, under pressure by filter-presses (on platform, Fig. 1), by vacuum in box-filters (Fig. 1, left), and by centrifuging (one small and one larger machine appear on the left in Fig. 2), is installed, and the principal operations involved in the later treatment of a filter-press cake—for instance, squeezing in a hydraulic press (Fig. 2) or in a screw press (Fig. 4, lying on floor), drying in evacuated steam-ovens, and grinding in an edge-runner mill (not shown)—are all provided for.

A word should be said regarding the steps which have been taken to solve the problem of ventilation. General ventilation is provided by a 36-in. fan work-

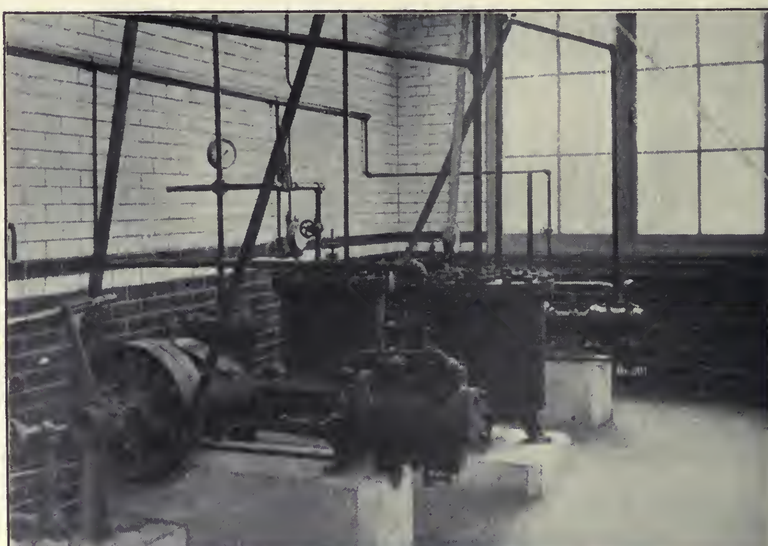

FIG. 5.—Vacuum and air-pressure services.

ing in an aperture in the wall. In addition, however, a main draught trunk, operated by a separate

fan, has been arranged to pick up vent-pipes and gas-flues from all digestors, as well as the exit pipes of the counterpoised draught-hoods which are pulled down over the evaporating pans when evaporations are in progress.

The surroundings of the laboratory are shown in some of the photographs. In Fig. 2 appears the adjoining research laboratory, whilst Fig. 4 shows a corner of the fitting-shop and engineering store. This invaluable adjunct contains a stock of pipes, fittings, and tools, some small power-driven machines, including a screw-cutting lathe, and working places for carpentering, fitting, and soldering. The chemical store, which is arranged to contain casks, drums, and carboys, as well as Winchesters, does not appear in the photographs.

With regard to the question of slinging and heavy work generally, the numerous overhead principals provide so many points from which a lifting block may be hung that it was not considered necessary to install a travelling crane. Two rubber-tyred bogeys, one of which has been specially designed, suffice for the carriage of all the heavier objects which we are likely to have to handle. J. F. T.

Great British Droughts.

By Chas. Harding.

It is fortunately seldom that such persistent dry weather has to be chronicled as that which has now continued for several months. A more complete history of the drought will doubtless be written when all possible facts have been collected.

At Greenwich Observatory the records show that the rainfall has been less than the normal for nine consecutive months, from October, 1920, to June, 1921. The total measurement for the whole period is 9·78 in., which is 7·74 in. below the average for the 100 years ending 1915, and only 56 per cent. of the normal. This is the driest period from October to June in the last 105 years; the next driest corresponding period occurred in 1879–80, when the measurement was 10·50 in. There is only one longer period at Greenwich—November, 1846, to January, 1848, a period of fifteen consecutive months—with the rainfall below the normal. The controlling factors of the weather have commonly been a low barometer in the north of the British Isles, and a relatively higher barometer with anticyclonic conditions in the South of England.

In addition to the Greenwich observations, those at Eastbourne have been chosen to represent the more southern portion of the kingdom. The drought at Eastbourne is scarcely so severe, since the rainfall for each of the months December, 1920, and January, 1921, was in excess of the average for the period of thirty-five years ending 1915, chosen as the normal by the Meteorological Office. The total rainfall for the nine months from October, 1920, to June, 1921, inclusive, is 15·62 in., which is 7·95 in. in defect, and 66 per cent. of the average fall. This is 10 per cent. of the average more than at Greenwich.

Attempts have been made from time to time to detect a weather cycle, but so far these have not been very successful. The favourite cycle with meteorologists is that corresponding with the periodicity of solar activity; but, so far as the general weather is concerned, it does not yield satisfactory results. Prof. Brückner, of Berne, has discussed the subject of periodic variations and changes of climate in detail, and his discussion is conducted on lines which perhaps might well be followed by others. For the fluctuations of rainfall he has made use of observations at 321 points on the earth's surface, and of these no fewer than 198 are in Europe. Prof. Brückner deals with averages for five years, and the period found for the cycle is thirty to thirty-five years. Continuing the cycle to the present time, a period of deficiency of rainfall is shown for the years 1921–25; the previous period of deficiency was 1891–95. The next period of excess should occur in 1936–40. The present deficiency of rain seems decidedly a fulfilment of Prof. Brückner's cycle.

An absolute drought is reckoned as more than fourteen consecutive days wholly without rain, and a partial drought is a period of more than twenty-eight consecutive days the aggregate rainfall of which does not exceed 0·01 in. per diem. No absolute drought has occurred at Greenwich this year, and the only partial drought was from February 1 to March 5, a period of thirty-three days during which the total rainfall was 0·24 in. The spring drought of 1893 is probably the most severe of recent years; the absolute drought continued for forty-four days, whilst the partial drought at Dungeness lasted for 127 days, and at North Ockenden, Romford, Essex, for 128 days. The abnormal summer of 1911 experienced three absolute droughts at Greenwich—April 11 to 24, fourteen days; July 1 to 23, twenty-three days; and August 2 to 18, seventeen days. There was an exceptionally long partial drought continuing for fifty days, from June 30 to August 18; the aggregate measurement of rain during the period was 0·33 in. As many as three absolute droughts occurred in London in the years 1868 and 1887, and four in the year 1858. In 1880 there was an absolute drought for twenty-eight days—from August 9 to September 5. In the year 1716 it is recorded that, in consequence of a long drought and a south-west wind, the River Thames became so low that thousands of persons passed across on foot under the arches of London Bridge.

There is a great diversity in the periodicity of rainfall, and two consecutive summers often differ widely from each other, as shown by the rains in 1920 and 1921. In 1903, a remarkably wet year, the aggregate measurement of rain at

Greenwich for the six months April to September was 22·21 in., whilst for the following summer, 1904, it was 8·69 in. "British Rainfall," dealing with observations from 1726 to 1891, shows that during the first forty years the rainfall in only nine years reached the average, and from 1738 to 1762, a period of twenty-five years, there is only one year above the average; this is a more persistent drought than has occurred in the nineteenth or twentieth century. There was a succession of wet years ending with 1882, and this was followed by a very dry period. In the twenty years 1883 to 1902 the Greenwich observations show an aggregate deficiency of rain amounting to more than 40 in. During this period there were sixteen years with a deficiency, one year with the average fall, and three years with an excess. Each year from 1895 to 1902 had a deficient rainfall, the total deficiency in the eight years amounting to 25·5 in.

The question of interest is now: When will the exceptional heat and drought of the present year cease? The absence of rain is continuing well into July, and each week the drought is becoming more serious over the whole country. The increased interest in meteorology, brought about by the late war, has added much to the staff and efficiency of the Meteorological Office. Every effort is being made to improve our knowledge of the weather changes, and probably in a few years it will become possible to predict the chief characteristic features of a season.

The Scarcity of Swallows.

By Dr. Walter E. Collinge.

For some years past certain ornithologists have directed attention to the decreasing number of swallows seen in the British Isles during the months from April to September. This diminution was particularly marked in 1918 and 1919, less so in 1920, but is still more apparent in the present year. For a time the scarcity was denied by many, or stated to be only of local occurrence, but the condition of affairs during the present season is sufficiently well marked to convince the most sceptical.

The swallow economically is one of our most valuable birds, its food consisting practically entirely of insects, and any scarcity of these birds removes a most important factor in the destruction of injurious insects. The causes which have led to this scarcity are not at present all known, but there are some which have been operating for a considerable time past, and their effects are now making themselves felt.

First, there is the deplorable mortality of migrants which takes place around our coasts in connection with the lighthouses and lightships, and, as has previously been pointed out, a considerable percentage of these birds might be saved. Something towards minimising this danger has already been done, but the swallow is a day-migrant, and so largely, if not entirely, escapes this danger.

The enormous increase of the house-sparrow during recent years has undoubtedly had much to do with the decrease of the swallow. Not only do the sparrows take up their abode in the swallows' nests, but they molest and persecute the birds during the whole period of incubation. In the United States there has of recent years been a very serious decrease in the number of house-martins due to this cause.

There are, however, other causes for the present scarcity which do not arise in this country. In 1918 and 1919 the continuous waves of June migrants were unobserved or of very short duration, and during the present season they have been still fewer, all of which clearly indicates a diminishing immigration. Moreover, in 1919 and 1920 the majority of the swallows commenced their southern migration early in August.

In view of the importance of the swallow economically, the question is one calling for immediate attention and investigation, and until we know more about the matter it might be well to place this bird and its eggs under stricter protection.

The King George V. Dock, London.

A function of special interest and importance in the history of the Port of London was performed on Friday last, when the King visited North Woolwich for the purpose of opening and naming the new dock of the Port of London Authority which has been under construction since 1912.

The addition to the enclosed water area of the port amounts to 64 acres, and as the depth of the dock is 38 ft., the new accommodation will prove extremely useful for large ocean-going vessels of the present day. The dock is entered by a lock 800 ft. long and 100 ft. wide, having a depth of 45 ft. over its sill at high water, and 20 ft. less at low water. The capacity of the chamber can be increased to a maximum length of 910 ft. by placing a *caisson* in a special recess instead of using the innermost pair of gates. The dock averages 600 ft. in width, but tapers from east to west. On the north side there is a concrete quay wall of the ordinary type. On the south side a somewhat novel arrangement has been adopted. Projecting into the dock, and parallel with the quay line at a distance of 54 ft. there-

from, is a series of seven jetties, 22 ft. wide, leaving an intervening space of 32 ft. in width between them and the quay. The object of this is to enable barges to pass on the inner side of the jetties, so that vessels may simultaneously discharge their cargoes into barges on both sides and, at the same time, land goods on the quay. The jetties are equipped with cranes which are able to command the vessel's hold, the inner barges, and the quay. It should be pointed out that a high proportion of the goods brought into the docks at London is conveyed by barge or lighter to their ultimate destination.

The north quay is to be flanked by double-story sheds, of which so far only one is constructed. These are designed in reinforced concrete, with brick panelling. On the south side seven single-story sheds of steel framing with corrugated-iron covering have already been provided.

At the western end of the new dock is a dry dock 750 ft. long with an entrance 100 ft. wide and a depth of water over sill of 35 ft.

Connection between the new dock and the adjoining Royal Albert and Victoria system is made by means of a passage 100 ft. in width.

The King graciously acceded to the request that the new dock should be called the King George V. Dock, and named it accordingly.

Notes.

THE Osiris prize of 100,000 francs has been awarded by the Academies of the Institute of France to Gen. Ferrié, C.M.G., Director-General of French Military Telegraphs, in recognition of his work in the development of wireless telegraphy for war purposes. Gen. Ferrié has been well known as an acknowledged authority on wireless matters for many years, and as the head of the French military wireless telegraph services it fell to him to initiate the whole organisation of the wireless arrangements in the fighting forces of France during a period when greater advances were being made than at any other time in its history. He was responsible for the equipment and working of the famous Eiffel Tower station and for the installation of the powerful station at Lyons in 1917, as well as for the completion of the still more powerful station near Bordeaux commenced during the war by the American Army. Gen. Ferrié had much to do with reducing the thermionic valve from a laboratory appliance to a piece of everyday wireless apparatus and in devising wireless equipment for aircraft, and in earlier days was one of the first successful experimenters with the electrolytic detector. In recognition of his work the honorary degree of D.Sc. has been conferred upon him by the University of Oxford.

SIR ROBERT HADFIELD has expanded his reply to the American deputation of engineers who attended in London to present him with the John Fritz medal into an address of thanks, which has just been printed in the form of a substantial pamphlet with numerous illustrations. The address sketches the services rendered by British and American engineers to the Allied cause during the war, outlines the record of the Institution of Civil Engineers, and gives an account of the members of the American deputation. The movement which has resulted in the establishment of the United Engineering Society of the United States is commended as having brought together a large number of distinct technical institutions, housed them in a common building, and provided a common library, so furnishing an excellent object-lesson in the organisation of scientific and technical effort. A description is then given of Sir Robert's own metallurgical research work, especially in regard to the invention of manganese steel, the alloy which possesses such an unusual combination of mechanical and magnetic properties, and of the alloy of iron and silicon, now so widely employed under the name of "low hysteresis steel" in the construction of transformers and other electrical appliances. The concluding sections of the address deal with the growth of science and the value of research to civilisation, the subject being illustrated by an account of the history of the Royal Society and of some of its more famous fellows. The present occasion is a good one for directing attention to the close bonds which unite men of science and technologists in our own country and in the United States, and to the advantages which are to be derived from an even closer co-operation in the future.

THE council of the Royal Society of Arts has decided that in future the Colonial section of the society shall be known as the "Dominions and Colonies Section."

MR. A. J. BALFOUR has been elected president of the British Academy in succession to Sir Frederic Kenyon. M. Henri Pirenne, past-president of the Belgian Academy, has been elected a corresponding fellow, and Bishop G. F. Browne, formerly Disney professor of archæology in the University of Cambridge, an honorary fellow of the academy.

THE following have been elected as officers and members of council of the North-East Coast Institution of Engineers and Shipbuilders for the session 1921–22:—*President:* Sir William J. Noble, Bart. *Vice-Presidents:* Mr. C. W. Cairns, Mr. A. Laing, Mr. C. D. Smith, and Mr. R. Wallis. *Members of Council:* Mr. B. C. Browne, Prof. C. J. Hawkes, Mr. R. Hinchliffe, Mr. H. Laing, and Dr. J. E. Stead. *Hon. Treasurer:* Mr. R. H. Winstanley.

IN accordance with the provisions of section 2 (6) of the Dyestuffs (Import Regulation) Act, 1920, the President of the Board of Trade has appointed a Committee to advise the Board with respect to the efficient and economical development of the dye-making industry. The members of the Committee are:—Mr. W. J. U. Woolcock, M.P. (chairman), Mr. Percy Ashley, C.B. (Board of Trade), Sir Henry

Birchenough, Mr. W. H. Dawson, Mr. G. Douglas, Mr. E. V. Evans, Dr. M. O. Forster, Mr. L. B. Holliday, Dr. Herbert Levinstein, Prof. G. T. Morgan, Mr. J. Morton, Mr. Max Muspratt, Mr. T. Taylor, Mr. N. Thomas (Admiralty), and Mr. G. S. Witham (War Office). An additional representative of dye-using interests is to be appointed shortly.

THE Royal Asiatic Society has decided to celebrate the centenary of the birth of the late Sir Richard F. Burton by the institution of an annual memorial lecture and a medal bearing his effigy. Burton was a pioneer and an explorer of the first rank who studied his fellow-men profoundly, and by his wonderful knowledge of the literature and life of the Arabs did much to bridge the gulf between East and West. His journeys to the forbidden cities of Mecca and Harer will long be remembered as exploits as full of daring as they were of scientific importance. A fund, to be known as the Burton Memorial Fund, has been opened and a national appeal for subscriptions is being made. The hon. secretaries of the memorial fund committee are Dr. F. Grenfell Baker and Mr. N. M. Penzer, and subscriptions should be dispatched to the Manager, the National Provincial Union Bank of England, Union Bank Branch, Oxford.

EMPHATIC corroboration of recent correspondence in our columns upon the supply and cost of German publications is provided by a letter addressed to the *Times* signed by the Vice-Chancellors of the Universities of Liverpool, Sheffield, and Manchester and the Principals of Armstrong College, Newcastle, and Birmingham University. At each of these institutions the librarians have found it impossible to obtain current German scientific literature by reason of the operation of the Reparations Act. There has been a complete stoppage of delivery through the Customs of books of German origin, while books which have been ordered direct from agents in Germany are delayed for an indefinite period. Even when it has been proved that the order was placed before the present Act came into operation and the 50 per cent. Customs charge has been paid under protest, books are still undelivered. The writers of the letter emphasise the fact that it cannot be regarded as patriotic to cut off from this country all knowledge of scientific progress in Germany; on the contrary, it is to the advantage of our trade and ultimate prosperity to know without delay every addition to knowledge made in Germany as in other countries. German journals of science and other publications devoted to the advance of knowledge cannot be regarded as entering into competition with British journals and books, and vigorous protest is made against the interpretation of the Act by the Board of Trade to include such articles.

THE University of Calcutta has published, as the first of its series of anthropological papers, an essay by Mr. Panchanan Mitra on the prehistoric arts and crafts of India. Beginning with stone implements, Mr. Mitra traces their development in the Palæolithic and Neolithic types. Then follows a chapter on cave paintings and carvings, containing much information which will be novel to English readers. These are held to indicate an Indo-Australian culture-contact from the late Palæolithic up to Neolithic times. On the general question of prehistoric arts and crafts the author accepts the view of Dr. Coomarswamy that "to this Mykenean facies belong all the implements of wood-work, weaving, metal-work, pottery, etc., together with a group of designs, including many of a remarkably Mediterranean aspect, others more likely originating in western Asia. The wide extension and consistency of this culture throughout Asia in the second millennium B.C. throw important light on ancient trade intercourse at a time when the eastern Mediterranean formed the western boundary of the civilised world." Thus the veil which has hitherto concealed the origins of ancient Indian culture is being gradually lifted, and the University of Calcutta is to be congratulated on its efforts to extend this knowledge by the aid of native scholars like Mr. Panchanan Mitra.

THE second part of Mr. Rhys Jenkins's paper, read before the Newcomen Society, on "The Rise and Fall of the Sussex Iron Industry" deals at some length with the technical aspects of the subject, although the historical material available is somewhat scanty. The ore most commonly used was a clay ironstone occurring in nodules and thin beds towards the bottom of the Wadhurst Clay. It was worked mainly by means of bell pits about 6 ft. in diameter at the top, which widened towards the bottom and were generally shallow, being rarely more than 20 ft. deep. These beds have been worked from Roman times onwards. Mr. Jenkins quotes in full the description of the process of iron-making published by John Ray in 1674. From this it is clear that the ironmasters always mixed together different kinds of ore. The roasting process is first described, and afterwards the method of charging and operating the blast-furnace. The period of six days was called the "Founday," and about eight tons of iron were made in this time. The methods of working the iron at the forge or hammer in the Finery and Chafery are also described. Mr. Jenkins concludes that the industry began to decline during the Commonwealth period, and became extinct about the end of the eighteenth century. He discusses possible reasons for this decay, and concludes that it was due neither to the competition of mineral fuel nor to a failure in the supply of charcoal. He appears to think that it may have been connected with the question of power used for working the bellows of the blast-furnace and the hammer of the forge. Water-power was used for this purpose throughout the country, and the Weald was inferior to, for instance, Shropshire as regards both rainfall and the head of water which could be utilised. The author also considers that foreign competition was more acutely felt in the Weald than in the northern districts.

THE June issue of the *Decimal Educator*, a quarterly publication of the Decimal Association, contains much interesting information respecting the progress of the metric system. The introduction of metric weights on the Chinese railways, which is now an accomplished fact, was effected without trouble and has given rise

to no complaints. A notice issued recently by the Government of Malta announced that the metric system was to come into force on July 1. It has been made obligatory in dealings with the Customs Department as a preliminary to enforcing its use in general trade in the island. The unsatisfactory manner in which decimals are taught in the United Kingdom is the subject of an instructive article in which it is stated that, although teachers as a body are supporters of the metric system, the accepted methods of teaching arithmetic place the decimal fraction in an unfavourable light by giving unnecessary prominence to conversion sums, and in this way seriously handicap decimal reform. It is urged that so far as possible all reference to vulgar fractions should be omitted from the teaching of decimals, and that the examples necessary to explain the meaning of decimals should be drawn from the metric system and decimal coinage, with an occasional sum involving such British measures or coins as are connected by decimal relations. A useful chart illustrates the progress made in the adoption of the metric system during the last hundred years. The consistently upward trend of the curve and the particularly sharp rise during the past ten years are noteworthy, and indicate that as each new country joins in the competition of international trade its national weights and measures are abandoned and the metric system adopted in preference.

THE National Institute of Agricultural Botany, which was organised with the object of improving the seed supply in the United Kingdom, is now making arrangements to conduct a comprehensive series of yield and quality trials of wheat, oats, and barley, to commence during the season 1921–22. The trials will be carried out on a uniform and scientific system in several parts of the country, and final reports, on which the granting of certificates of merit will be based, will be issued after the harvest of 1924. The trials will be open to all who can show that they have in their exclusive possession new or improved varieties or strains of any of these cereals, and undertake to refrain from placing them on the market previous to the issuing of the final report on their merits, except with the institute's consent. The testing fee will be limited to the actual cost of the trial. Full particulars of the scheme can be obtained from the Secretary, National Institute of Agricultural Botany, 10 Whitehall Place, London, S.W.1.

Nos. 1–9 in vol. vi. (1920) of the Entomological Series published by the Agricultural Research Institute, Pusa, are devoted to a series of papers on the life-histories of Indian Microlepidoptera by Mr. T. B. Fletcher. It is mainly within the last fifteen years that any serious attempt has been made to acquire a knowledge of the species of the small moths which occur in India. In 1889 only 225 had been enumerated, while at the present time 2422 species contained in about 458 genera are known. In spite of this large number, Mr. Fletcher remarks that we are merely beginning to learn what kinds exist in the Indian Empire, where there are still enormous areas absolutely unknown so far as Microlepidoptera are concerned. In this series of papers a great deal of scattered information is brought together in a convenient form, and short accounts are given of the life-histories of a very large number of species. Many of the latter, together with their larvæ and pupæ, are well figured in a series of sixty-eight plates which accompanies the letterpress.

DR. MARJORIE O'CONNELL (Bull. Amer. Museum Nat. Hist., vol. xlii., p. 643, 1920) describes Jurassic ammonites from Viñales, western Cuba, which prove the beds containing them to be of Oxfordian age. The author points out that in a recent paper by Dr. M. S. Roig previous descriptions of Mexican species have become included as though they came from Cuba. More may be expected, however, from Dr. Roig's extensive collections, and Dr. O'Connell will, no doubt, pursue her studies in this almost untouched field.

IN Bulletin 597 of the U.S. Geological Survey, with its large geological map on the scale of 1 : 250,000, Mr. B. K. Emerson provides a handbook to "The Geology of Massachusetts and Rhode Island," a region associated with Boston Bay, one of the most famous natural gateways of North America. Students at Harvard and citizens of Providence in the drowned valley of the Blackstone River, or of Pittsfield across the picturesque and dissected uplands of Berkshire, will welcome this record of the geological history of their States. Fascinating reproductions of the early Dinosaurs of Triassic times are given from models, including Stegomus, known from its armour only, and the bipedal Anchisaurus. The reader requires geological training, but this should not be lacking in the abundant secondary schools of Massachusetts.

SPECIAL interest attaches to a recently published Bulletin of the U.S. Geological Survey on "The Iron and Associated Industries of Lorraine, the Sarre District, Luxemburg, and Belgium," by Messrs. Alfred H. Brooks and Morris F. La Croix. The bulletin gives an exhaustive description of the position in these districts and of their future possibilities, and is full of valuable statistical information most carefully collected. At the moment the following passage, written with reference to the Sarre coalfield, is perhaps the most interesting for British readers:—"It has long been recognised in Germany that the Government mines were less efficiently operated than those in private hands. Evidence of this difference is found in the reported cost of production. The average cost per ton of coal mined in the years 1906 to 1910 was 11.54 francs for the private mines and 13.50 francs for the Government mines. This ratio of cost appears to have continued for 1913, when the average profit, as reported, was 2.50 francs per ton for private mines and 2.15 francs per ton for Government mines, in spite of the fact that the private operators sold their coal cheaper than the Government. . . . Further evidence of the better practice in the private mines is afforded by the annual coal recovery per miner, which in 1913 was 261 tons for private mines and 229 tons for Government mines."

PERTHSHIRE has been fortunate in that on two occasions when there was a fall of meteorites specimens and data of a trustworthy nature have been obtained.

In the latest issue of the Transactions and Proceedings of the Perthshire Society of Natural Science (vol. vii., part 2, 1919–20) Mr. Henry Coates describes fully all the data regarding the occurrence of the meteoritic fall in December, 1917, and the paper contains appendices regarding the fall of 1830, records of distances contained in tabulated form, and a report by Mr. W. F. Denning on the path of the meteor. The author has added eleven illustrations from photographs taken at the time and some diagrams. This part of the number also contains a short paper on the occurrence of the horned pond-weed (*Zannichellia palustris*, Linn.) in Keltie Loch, near Dunning, by Mr. J. R. Matthews.

ACCORDING to an article in *La Nature* for June 25, the French Navy, during the recovery of materials from many of the vessels sunk during the war, has greatly improved the oxy-acetylene torch of Picard so that it can be used under water. The addition which has rendered this possible is a small bell-shaped vessel surrounding the oxy-acetylene flame, which is kept supplied with compressed air. After the flame is alight and the stream of compressed air established the torch may be plunged into water without being extinguished. If by any accident it was extinguished, it was necessary for the diver to ascend to the air to light it again. Under the auspices of the French Department of Scientific and Industrial Research, M. Corne has recently made a further addition to the torch which makes it unnecessary to ascend to relight it. A tube containing an alkaline metal and an oxidiser is attached to the torch and can be moved to the mouth of the bell. On removing the cap from the end of the tube the chemical action of the water on the mixture produces a flame which relights the torch. The addition has greatly increased the number of under-water uses to which the torch can be put.

THE Journal of the Washington Academy of Sciences for April 4 contains two communications which deal with the steps taken by the United States to acquire a better knowledge of the properties and behaviour of the oceans which wash its shores. Under the auspices of the National Research Council a conference of representatives of the nations around the Pacific Ocean was held in Honolulu in August, 1920, to consider what knowledge with regard to that ocean was available and in what directions there was most urgent need of its extension. As a result, it is expected that during the present year several volumes dealing with the scientific exploration of the Pacific will be published. The opportunity afforded by the Ice Patrol of the Atlantic in 1920 was utilised by Mr. A. L. Thuras, of the Bureau of Standards, to test the trustworthiness of the method of determining the salinity of sea-water on board ship by measuring its electrical conductivity. It was found both trustworthy and convenient, and it is proposed to set up a self-recording apparatus based on the method which will give the temperature, density, and salinity of the water.

IN a paper read to the Physical Society on June 24 Mr. S. Butterworth discusses the errors due to capacity and eddy-current effects in inductometers. At low frequencies these errors are negligible, but at telephonic frequencies they have to be considered, and in radio-telegraphy the corrections which have to be applied are of the same order as the quantities measured. Making the assumption that the capacity effects in two coils having one end in common can be represented by two condensers shunting each coil and by another condenser joining their free ends, the author obtains formulæ which are in good agreement with experiment. When the secondary e.m.f. induced in a secondary circuit is in exact quadrature with the current in the primary the mutual inductance is "pure." This assumption is made in the proof of the Heaviside and Carey-Foster inductance bridges. The author works out the theory of these bridges on the assumption that the mutual inductance is not pure, but varies with the frequency. Experimental verifications of the theory are given.

IN the Journal of the Franklin Institute for May last L. W. Austin describes experiments made to determine the directions from which the atmospheric disturbances noticed in radio-telegraphy appear to come. The main observations were made in the West Indies, California, and Washington. The author concludes that on the Atlantic coast of the United States the disturbances come either from the direction of Mexico or from that of the Allegheny Mountains. On the Pacific coast the disturbances are much weaker and their direction is more variable. They seem to come from centres at much shorter distances, and generally in the direction of mountains. At Bremerton and Astoria most of the disturbances come from the direction of Mount Ranier, a lofty and isolated peak. In Porto Rico the disturbances were mainly of local origin and very diffuse. When they came from the sea there was generally land at no great distance in that direction. When the disturbances increase with increase of wave-length, as at Washington, they come from distant origins; when they vary little with wave-length, as at San Francisco and San Diego, the focus of the disturbance is near at hand. The origin of the disturbances seems to be in the upper atmosphere, probably between masses of air at different potentials. The results obtained indicate that a world-survey of these "static" disturbances would lead to important results.

IN electroculture it is customary for the high potential wires to be placed horizontally and parallel to one another above the growing crop. As the number of wires is limited the question arises as to how far the electric force at the ground level is uniform. In a paper to the Physical Society read on June 24 Dr. Chree gives simple formulæ showing how the potential gradient at the surface of zero potential (generally the ground level) depends on the height and spacing of the wires. These formulæ will be of use in practical work. It is probable that a high potential gradient is injurious, and a low potential gradient beneficial in certain cases. It is important therefore to obtain uniformity of conditions, for this should at least make it easier to draw conclusions as to the merits of electroculture. An immediately useful deduction from the author's formulæ is that a very uniform set of conditions can be secured

at crop level if the distance between adjacent wires does not exceed the height of the wires above the crop. It has to be remembered, however, that when there is an appreciable excess of ions of one sign in the atmosphere the values of the electric forces will be affected.

It is well known that Hooke's law of proportionality of force applied and deformation produced holds for solids only so long as the deformation is not large. The same may be said with regard to the corresponding law for the deformation of viscous liquids. In order to discover some more satisfactory form of relation between deformation and force in either case, Dr. P. G. Nutting has made observations of the shear of various materials between parallel plates 5 cm. by 10 cm. in area and 0·2 cm. apart; his results are given in the May issue of the Journal of the Franklin Institute. He finds that in all cases the deformation at a given temperature is proportional to a power of the force which varies for different materials from 0·74 to 3·5. Further, it is proportional to a power of the time of application of the force, which varies for different materials from 0·2 to 0·91, the low value being characteristic of solids and the high one of liquids. Dr. Nutting finds that the new law is applicable in other than mechanical fields. In a dielectric, for example, the electrical displacement is proportional to a power of the applied electric field, which varies from 0·54 for paper to 1·16 for xylene, and also to a power of the time of application of the field, which varies from 0·74 for bakelite to −0·2 for mica. For the best technical insulating materials the power of the force is nearly 1·0 and the power of the time nearly zero.

About six months ago Lüppo-Cramer published his discovery that phenosafranine has the remarkable property of desensitising photographic plates without interfering with the developable image that has been impressed on them, as in the course of ordinary exposure. We have already referred to this and to the solution that Messrs. Ilford have put upon the market that enables the most sensitive plates to be developed with no more precaution as to the safety of the light than would be necessary if the plates were one two-hundredth, more or less, as sensitive as they are. In the *British Journal of Photography* for June 17 and 24 Messrs. A. and L. Lumière and A. Seyewetz give details of experiments they have made on this subject. They have examined the desensitising action of a large number of other safranines, and find that while several are comparable in this matter to phenosafranine, none show any appreciable advantage to it, except that cresosafranine is more easy to wash out of a gelatine film. Many other organic bodies show a notable, and even useful, degree of desensitising effect, but for general purposes phenosafranine is superior to them all. There appears to be no well-defined relation between the constitution of dyes and their desensitising properties. Phenosafranine does not act merely as a light-filter, for it transmits red and violet, for both of which it desensitises. But if the plate is washed after treatment with the desensitiser, as the dye disappears the original sensitiveness is restored. It is therefore assumed that the dye forms an adsorption complex of much lower sensitiveness than the original silver bromide, and that this complex is unstable enough to be gradually decomposed by water. The authors have also examined plates treated with various typical desensitisers by exposing them in a spectrograph and estimating the loss of sensitiveness to light of different wave-lengths.

The summer meeting of the Association of Science Teachers was held at Cambridge on July 9. In the afternoon Dr. Aston gave a lecture at the Cavendish Laboratory on "Atoms and Isotopes." Early ideas of the structure of matter, leading up to the formulation by Dalton of the atomic theory, were reviewed, and it was shown that the progress made in chemistry during the nineteenth century, which depended on the exact work done in the determination of atomic weights, had been inspired by Dalton's postulates. In order to explain fractional atomic weights, Crookes had suggested that an element might be a mixture of atoms of varying weight, but this was regarded as unlikely until in 1910 Sir Ernest Rutherford's work on radio-activity showed that various forms of lead obtained by radio-active changes had slightly different atomic weights, though their chemical properties were identical. To these substances Prof. Soddy gave the name of "isotopes." The method of positive-ray analysis due to Sir J. J. Thomson was then utilised. By this means it was found that neon—atomic weight 20·2—was probably a mixture of two isotopes of atomic weights 20 and 22, and after much labour a gas was obtained differing in density by 0·7 per cent. from the original, the experimental error being 0·2 per cent. This was not conclusive, but more exact methods of positive-ray analysis have shown that neon is made up of two constituents of atomic weight 20 and 22 in the ratio of about 9 to 1. Similarly, chlorine has been shown to consist of at least two isotopes of weights 35 and 37, and quite recently they have been separated. The work done shows clearly that the important property of an element is the atomic number or the positive charge on the nucleus of the atom, and it is this alone which determines the chemical properties of the element.

The Journal of the British Science Guild for June contains an article by Sir Richard A. S. Redmayne on the world-position in relation to coal. Great Britain has been unfortunate in her recent experiences. Prior to the war she exported about 73,000,000 tons of coal *plus* 21,500,000 tons shipped as bunker coal, making 94,500,000 tons, or 32 per cent. of her total output. But in 1919 this total was only 47·3 million tons, 20·6 per cent. of the production. In the present year the figures will doubtless be still more unsatisfactory. Other countries have also produced less coal. The entry of China as a competitor in the coal markets of the West is significant. Oil, it is stated,

cannot become a real menace to the coal trade, as the amount available is only one-sixteenth of that needed to displace coal, and much of this is required for other purposes. A summary of addresses delivered at the annual dinner of the Guild by Field-Marshal Sir William Robertson, Col. Sir Ronald Ross, the Very Rev. Dean Inge, the Right Hon. Lord Rayleigh, and the Right Hon. Lord Bledisloe is also included in this issue of the Journal. Sir William Robertson made some illuminating comparisons between military experience of the past and the scientific warfare of the present day. He remarked that the day of the amateur is past, and that those who aspire to exercise Ministerial control over the destinies of this country should attach greater importance to the value of science. The administrative activities of the Guild fill a considerable portion of the issue. Special importance attaches to the report of the Committee on the Utilisation of Science in Public Departments, attention being directed to the position of scientific research workers in regard to tenure of service, salary, superannuation, etc. The attitude adopted by the Scientific Research Department of the Admiralty towards the individual university worker whose researches bear on Admiralty requirements is spoken of with approval.

A FAVOURABLE opportunity of obtaining books in general literature and on scientific subjects in new condition at prices considerably below those at which they were published is presented by Messrs. W. Heffer and Sons, Ltd., Cambridge, in their "Remainder" catalogue (No. 201), which has just been issued. It contains 485 titles, and is worthy of perusal.

THE most recent catalogue of Mr. F. Edwards, 83 High Street, Marylebone, W.1, is No. 416, entitled "Australasia and the South Seas." It gives particulars of some 813 works relating to Australia, New Zealand, Tasmania, New Guinea, and the islands of the Pacific. Some very choice and rare volumes are included.

Our Astronomical Column.

RECENT METEORS.—Mr. Denning writes:—"On July 5 there were two showers in prominent activity, supplying large, slow-moving meteors. The radiants were at $243°+65°$ and $228°+58°$. These positions are some distance east of the radiant point computed for Pons-Winnecke's comet, but it is possible the comet and meteors may be associated, the discordances having been brought about by perturbations. Fireballs were observed at Bristol on July 5 11h. 40m. G.M.T. from radiant $243°+65°$, on July 9 11h. 54m. from radiant $238°+18°$, and 12h. 47m. from radiant $343°+12°$. A well-defined shower of swift, streaking meteors was observed from the latter position on the night of July 9."

ANOTHER PLAN OF CALENDAR REFORM.—Prof. René Baire (Dijon) contributes an article to *Revue Scientifique*, 1921, No. 9, in which he points out several drawbacks (chiefly from a statistical point of view) attaching to the proposal to place certain days in each year outside the weekly and monthly reckoning. His plan of evading the difficulty is bold and novel, and consists in shortening the greater number of weeks to six days. A Saturday would occur only on the thirty-first day of the month—that is, five times in the year or six times in leap-year. The months are left nearly as at present, but the missing days of February are supplied. The following is the suggested table:—January 30, February 30, March 31, April 30, May 31, June 30, July 30, August 31, September 30, October 31, November 30, December 31. In leap-year July has 31 days.

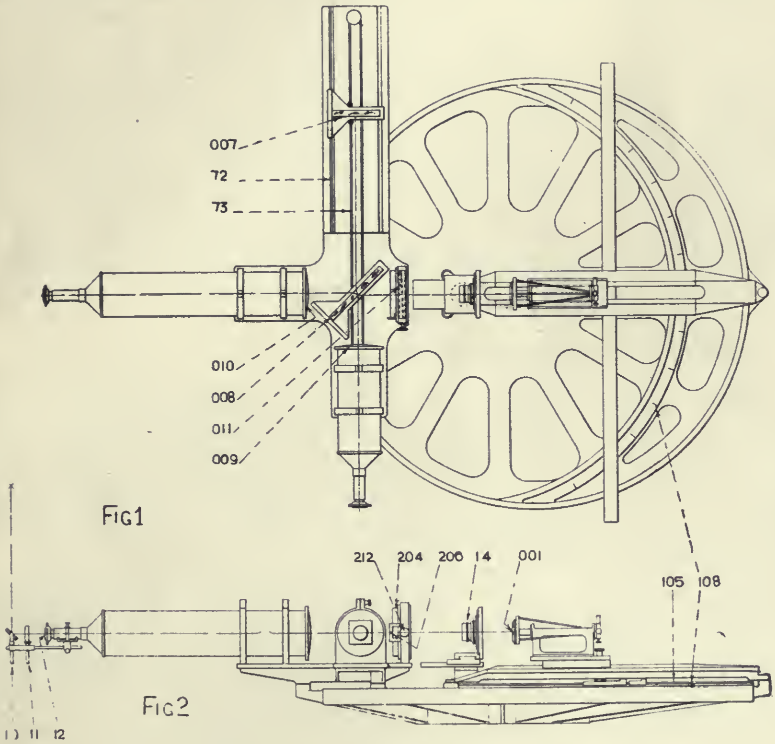
The 1st, 7th, 13th, 19th, and 25th days of each month would be Sundays; there would thus be sixty Sundays in the year instead of the present fifty-two or fifty-three. The author seeks to disarm ecclesiastical criticism by pointing to this increased number; he also notes that the feasts of January 1, November 1, and December 25 would always occur on Sunday, while if Easter were fixed to the date April 1 it would be preceded by a Saturday. It is proposed that the additional Sundays should take the place of the present Bank Holidays, thus making the number of working days in the year much the same as at present.

While the scheme has some obvious advantages, it is doubtful whether public opinion could be brought to sanction such a revolutionary change.

THE VARIABLE NEBULA IN CORONA AUSTRALIS.—Bulletin 20 of the Helwan Observatory contains a photographic research by the director, H. Knox Shaw, of the variability of this nebula and the neighbouring star R Coronæ Australis. The star magnitudes were deduced by comparison with standard fields at the same altitude, the incidental result being derived that the graph connecting magnitude with diameter of image shows decided curvature in the direction of enlargement of the image of the fainter stars. There are five variables in the field besides R Coronæ, viz. S and T Coronæ, C.P.D. $-37·8450°$ (shown by Mr. Innes to be an Algol variable with period just under twenty-six days; a minimum of this star was observed at Helwan in 1915 August 9) and two other stars. Except for the Innes star, the variations appear to be irregular, and Mr. Knox Shaw conjectures that they may be due, wholly or in part, to the absorbing medium which he assumes to cover the whole region, as its star density is distinctly less than that of the neighbouring sky. The variability of the nebula is next discussed. Its structure is shown to be made up of a series of rings and knots, which apparently remain *in situ*, but alter in relative brightness. This is analogous to the behaviour of the nebulosity round Nova Persei, and Mr. Knox Shaw has examined the results to see if there is any connection between the changes of the star R Coronæ and those of the nebula. There is suspicion that the nebular changes follow those of the star at a ten-day interval, but the interruptions of the series of photographs by moonlight render it difficult to confirm this. If correct, and if it be due to an emanation travelling from the star with the velocity of light, the distance of the object would be about 100 light-years. It is pointed out that Hind's and Hubble's variable nebulæ are also near variable stars, and in regions of the sky that give evidence of the intervention of absorbing matter.

An Interferometer for Testing Camera Lenses.[1]

INTERFEROMETERS for the testing and correction of prisms and of lenses (for axial pencils) have been described in the *Philosophical Magazine* (vol. xxxv., January, 1918, p. 49). In its simplest form the instrument resembles the well-known Michelson interferometer, the essential optical difference being that the two interfering beams of light are brought to a focus at the eye of the observer. The principles of the prism interferometer have been applied to photographic lens testing in the camera lens interferometer recently constructed by Messrs. Adam Hilger, Ltd. A plan of the instrument is shown in Fig. 1, and a side elevation in Fig. 2. Light from a suitable source is reflected by a mirror 10 into the interferometer. A convex spherical mirror 001 is so disposed that its centre of curvature coincides with the focus of the lens 14 which is under test. In these circumstances, a beam the wave-front of which is a plane perpendicular to the axis of the lens will, after passage through the lens, be reflected back on its own path by the convex mirror, and if the lens be free from spherical aberration the reflected beam will, after passage through the lens, once more have a plane wave-front. If it has not, then the departure from planeness will produce interference bands which form a contour map of the corrections which will have to be applied to the lens to make its performance perfect.



FIGS. 1 and 2.—Plan and side-elevation of lens interferometer.

An apparatus which will test for axial pencils only is, of course, of little use for testing camera lenses. The modifications essential for the latter purpose are (1) means of rotating the lens about a line at right angles to the axis and passing through the second principal point, and (2) mechanism whereby, simultaneously with the above rotation of the lens, the convex back-reflecting mirror is automatically moved away from the lens in such a way that its centre of curvature always falls on the plane, perpendicular to the axis of the lens, on which the lens is desired to form its image. The rotation of the lens carriage is effected by means of a bar 105 parallel to the axis of the lens and extending to the outer edge of the interferometer. The second requirement is fulfilled by a flexible connection being led from the carriage on which the mirror is adjustably mounted and over a pulley to a weight, and by there being upon the carriage a roller which by the action of the weight is retained in contact with a cross-bar mounted on the axial bar 105 and at right angles to it.

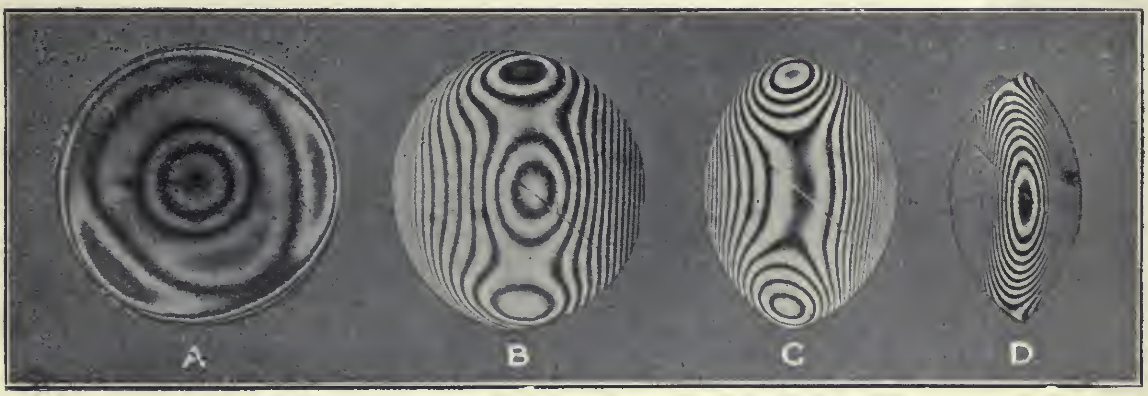


FIG. 3.—Interferograms of a photographic lens for axial and oblique beams.

[1] Abstract of a paper read before the Optical Society on April 14 by F. Twyman.

Adjustments are provided for bringing the second principal point of the lens under test on to the axis about which it is rotated by the bar, and also for bringing the centre of curvature of the mirror exactly on the axis of the roller above-mentioned and on the optical axis of the lens. The distance from the centre of the roller in the axial position to the axis of rotation of the lens is measured by a vernier. When all adjustments have been made, this vernier gives the focal length of the lens to an accuracy of about 0·001 in.

The apparatus measures the degree to which the wave-front, impressed by the lens on light from a distant point source, differs from a spherical wave-front. The indications are given in aberrations of wave-front to a scale of wave-lengths, the aberration shown being in every case twice that present in the once transmitted beam which normally forms the image of a distant point. The form in which the indications are presented is that of a series of interference fringes which are lines of equal aberration of wave-front. These interferometer pictures can be translated into terms of geometric optics by an observer who has had a little practice with the instrument. The various types of aberration and their chromatic variations produce characteristic interference patterns, and thus they can be readily differentiated and measured in terms of wave-length. By means of the pair of deflectors on a measurement of the distortion can also be obtained.

With a suitable source of light and a suitable camera the interference patterns can be photographed, and a complete photographic record can be obtained of the performance of any camera lens. Fig. 3 is a photographic reproduction of the interferograms of a well-known lens of high repute for the green mercury radiation ($546\mu\mu$) for the axial beam and for obliquities of 5°, 10° and 15°. It will be seen that even the best photographic lenses—of which this is a fair example—are very far indeed from perfection.

Mutations and Evolution.

In the series of articles by Dr. Ruggles Gates appearing under the above title in a *New Phytologist* Reprint (No. 12), published by Messrs. Wheldon and Wesley, Ltd., we have the most recent attempt to present a reasoned and comprehensive statement of the problem of evolution. As the author tells us, his aim has been to show that though germinal (by which apparently we may understand chromosomal) changes are of importance in the evolutionary process, they cannot be considered as all-sufficing; that only from the Neo-Lamarckian point of view is it possible to explain a large class of organic phenomena. From this point he sets out to show how the Darwinian doctrine and Mendelian conceptions in combination may furnish us with a solution. To this end, however, it scarcely seems necessary to maintain, as the author is at pains to reiterate, that in the application of Mendelian principles we are merely putting into use a refinement of the theory of natural selection. Nor does any point appear to be gained by this insistence on accord, since, by the author's own showing, the underlying difference between Darwinism and Mendelism—the difference, namely, between the idea of continuity and discontinuity—is profound enough to have divided biologists into two opposite camps. One feels that what is common ground might more easily be made apparent if an attempt were made to define more strictly, or else to abandon, terms which are used to cover an ever-increasing complex of ideas. It will be obvious, for example, that a fresh analysis of evolutionary processes should be couched in terms which clearly differentiate the causes (=true factors) to which variation is presumably due from the mechanism by which variations, once having appeared, are perpetuated, and from conditions which permit or limit the occurrence of variation. That the author evidently has in mind the necessity for precision in this connection appears from the fact that he is careful to point out that isolation due to geographical barriers must be regarded as a *condition*, and not as a *factor*, yet he fails to draw this distinction when dealing with natural selection.

The important point which Dr. Gates seeks to establish is that a new character may arise in *two* different ways: (1) as the result of what we have still to term *spontaneous* nuclear (=karyogenetic) mutations; (2) from a so-called organismal change, *i.e.* a change due either to environmental effects on the cytoplasm or to the morphological principle known as orthogenesis. In the first case the mutation is perpetuated through the *whole* cell-lineage, and the associated character is inherited as a unit. In the second *a localised region or a particular stage in the life-cycle* only is usually affected. Perpetuation of an organismal modification connotes the inheritance of acquired characters.

Mutations.—The more striking observations of Morgan and other American workers on Drosophila and of de Vries, the author, and others on Œnothera, which indicate a direct relation between chromosomal behaviour and somatic appearance, are set forth. Definite zygote characters are shown to be constantly associated with definite irregularities in the meiotic division, as, *e.g.*, the *lata* habit in Œnothera with the presence of an extra chromosome. The author brings forward evidence of independent sporadic appearances of this form, and a parallel mutation has been obtained in cultures of other Œnothera species. In every case the number of chromosomes was found to be 15 instead of the typical complement 14. The occasional occurrence of an 8–6 instead of a 7–7 separation of the chromosomes in another mutant form supplied the clue to the mode of origin of these 15-chromosome forms. In another instance a particular strain of Drosophila, indistinguishable in general from the normal but showing an aberrant type of inheritance, led Bridges to infer the duplication of a sex-chromosome—a prediction which later investigation proved to be correct. These forms with an extra chromosome are found seldom, if ever, to breed true. Their importance, according to the author, lies in the support which they give to the conception of the origin of a zygotic character from a nuclear mutation rather than in their significance in evolution. It is held to be otherwise, however, when the whole chromosomal equipment is duplicated (tetraploidy) and associated with a characteristic giant habit as in Primula and Œnothera.

The separate class of Mendelian mutations is regarded as due also to a nuclear change (in this case possibly chemical) which is presumed, however, to affect only a particular locus or element in the chromosome. It is clear, however, from Bridges's observation cited above, and from Heribert-Nilsson's work on Salix (which the author does not discuss), that, on one hand, duplication of chromosomes *need not* be accompanied by any gross change in the organism, and, on

the other, that a Mendelian mutation *may* produce an alteration in habit as marked as that which characterises the Œnothera forms with an extra chromosome. This being so, what becomes of the author's scheme of classification?

Organismal Characters.—The conception of organismal characters has been developed primarily, apparently, to account for the phenomenon known as recapitulation, *i.e.* the appearance in the individual of ancestral structures in a reduced or functionless form. In his treatment of this part of the subject the author is not easy to follow. Much of the argument advanced appears, and is admitted, to be inconclusive. The reader is left wondering why the "species cell" concept which has sufficed as a basis of explanation for karyogenetic mutations is here abandoned, and why physiological considerations are ignored. The essence of the conception of the "species cell" is, we are told, that when a new form arises it does so in consequence of some antecedent change in a (germ) cell unit. The individual derived from such a mutated germ-cell will exhibit the associated character in all its parts. The reasoning from this point onwards seems to be as follows:—If organisms were entirely composed of such cell units, then germinal mutations might supply the whole basis for evolution. But regions or structures occur in the organism in which the cell unit is ill-defined or non-existent, therefore some other type of evolution must take place [!] It does not appear, however, that it is in these regions or structures that the postulated environmental effect is felt. In fact, the line of argument now seems to lose touch with the cell altogether, and to work backwards from the other end, thus:—Recapitulation occurs, therefore at some point a lengthening of the life-cycle must have taken place. This can have come about only through additional cell-divisions taking place either at the end or in the course of the original cycle. Having laid it down that a *germinal* mutation is required to produce a new character, the author is driven to conclude that this extension of the life-cycle cannot be due to a change in a cell unit, "but must rather be the result of the organism, as it were, overcoming its cell-shackles and by its own energy [not, be it noted, through an environmental effect, as by the definition we are led to expect] producing new developments, though such novel additions are themselves cellular in structure." Somewhat earlier in his argument the author chides those who "desert science for obscurantism," but what are we to call this?

Though it may be that the reader will not feel that the author's conceptions of evolutionary processes materially advance the position, he will, nevertheless, find in these articles a useful collection of pertinent data.

University and Educational Intelligence.

LIVERPOOL.—Following the recent transfer of the Port Erin Biological Station to the University (Department of Oceanography), Mr. Herbert C. Chadwick, who has been curator under the Liverpool Marine Biology Committee for the last twenty-four years, has now resigned, but remains on the staff of the institution as research assistant. Mr. J. Ronald Bruce has been appointed naturalist-in-charge, and official letters should be sent to him.

ST. ANDREWS.—The following honorary degrees were conferred at the annual graduation ceremony on July 12:—*LL.D.:* Prof. W. M. Bayliss, professor of general physiology in University College, London; Sir William Henderson, chairman of Dundee Technical College; Emeritus Prof. D. MacEwen, Dundee; and Prof. A. N. Whitehead, professor of applied mathematics in the Imperial College of Science and Technology.

AMONG the bequests of the late Dr. H. Barnes, vice-president and a former president of the British Medical Association, are his medical books to the Royal Society of Medicine, and, conditionally, 2500*l.* to Edinburgh University for a scholarship for clinical medicine and 1500*l.* to Epsom College for a similar scholarship.

THE Paton-Figgis scholarship, value 50*l.* for a year and renewable, is being offered by the South-Eastern Agricultural College, Wye, Kent. Candidates must be reading for the B.Sc. (Agric.) degree, and reside outside the counties of Kent, Surrey, and Sussex. The latest date for applications to reach the Principal of the college is August 14.

THE following appointments have been made at the University College of Swansea:—Mr. F. A. Cavenagh to the chair of education; Dr. Florence A. Mockeridge, lecturer in botany and head of the department of biology; Mr. L. B. Pfeil, assistant lecturer in metallurgy; Mr. A. Stuart, assistant lecturer in geology; and Mr. J. S. Caswell, demonstrator in engineering for one year.

THE Ellen Richards research prize of 1000 dollars (200*l.*) is being offered by the Association to Aid Scientific Research by Women. Theses by women, based on independent laboratory research, are eligible for competition if received by the committee before February 25, 1922. Further information and application forms are obtainable from Dr. Lilian Welsh, Goucher College, Baltimore, Maryland, U.S.A.

Two Royal School of Mines Frecheville research fellowships, in aid of research in connection with mining, mining geology, metallurgy, or the technology of oil, are being offered by the Imperial College of Science and Technology, South Kensington, S.W.7. The fellowships are of the annual value of 300*l.*, tenable for one year, with a possible renewal for a second year. Applications, giving particulars of the candidate's proposed investigation, his qualifications and references, must be sent to the Secretary of the college before September 1 next.

WE have received from Mr. G. D. Dunkerley, hon. secretary of the Secondary School Teachers' War Relief Fund, the report of the last year's working. The object of the fund is to supplement the pensions and allowances of soldiers, sailors, nurses, and their dependents, and to secure that the families of the fallen and disabled secondary-school teachers shall suffer to the least possible extent in material circumstances. A total of 9874*l.* has been collected, and allowances are now being made to the extent of 481*l.* per annum. Thus the present capital fully safeguards the present allowances, and leaves a margin for additional help. The committee has therefore decided to maintain the payments from capital and interest combined without appealing for further funds, the capital diminishing as the necessity for the allowances ceases. Every opportunity will be taken of helping the children of fallen teachers at future stages in their careers, and although it has been decided to close the subscription list in its present form, the committee will gratefully accept legacies or donations for this special purpose. The chairman of the committee is Mr. A. A. Somerville, of Eton College; the hon. treasurer is Mr. J. Hart-Smith, of the County Secondary School, Battersea, and donations should be sent to him, c/o Barclay's Bank, 835 Wandsworth Road, S.W.8.

Calendar of Scientific Pioneers.

July 14, 1827. Augustin Jean Fresnel died.—An officer in the Corps des Ponts et Chaussées, Fresnel during the last twelve years of his life devoted himself to experimental and mathematical researches in optics. Like Young, he did much to establish the undulatory theory of light.

July 14, 1879. Sir Thomas Maclear died.—Trained as a doctor, through Admiral Smyth Maclear took up astronomy, and from 1833 to 1870 was Royal Astronomer at the Cape of Good Hope. Among other work was his extension of Lacaille's arc of meridian.

July 14, 1907. Sir William Henry Perkin died.—The discoverer in 1856 of the first of the aniline dyes, aniline purple or mauve, Perkin established a factory for its manufacture, and thus became the founder of the great coal-tar colour industry. His success, especially with the manufacture of alizarin, enabled him in 1874 to retire, after which he made important investigations of questions of chemical constitution. He was knighted at the jubilee of his great discovery.

July 17, 1878. Thomas Oldham died.—After holding the chair of geology at Trinity College, Dublin, Oldham in 1850 was appointed by the East India Company the first Superintendent of the Geological Survey of India.

July 17, 1899. Charles Graves died.—The successor of McCullagh in the chair of mathematics in Trinity College, Dublin, Graves contributed mathematical memoirs to *Crelle's Journal*, and served as president of the Royal Irish Academy.

July 17, 1912. Jules Henri Poincaré died.—Born in Nancy in 1854, Poincaré in 1908 was elected president of the Academy of Sciences of Paris, by which time he had written 1300 books and memoirs relating to pure mathematics, mathematical physics, astronomy, and philosophy.

July 18, 1650. Christoph Scheiner died.—A member of the Society of Jesus and an opponent of the views of Copernicus and Galileo, Scheiner was one of the earliest observers of sun-spots. He taught at Freiburg (Baden), Rome, and Ingolstadt, and was rector of a Jesuit college in Silesia.

July 18, 1819. Barthélemy Faujas de Saint-Fond died.—Attracted to natural history by Buffon, Faujas de Saint-Fond became professor of geology in the Jardin des Plantes. He travelled much, wrote a valuable work on extinct volcanoes, and was the first scientific writer to direct attention to the basalt pillars of the Isle of Staffa.

July 19, 1814. Matthew Flinders died.—Known for his important survey of the Australian coast, Flinders made observations on the compass, and to him we owe the "Flinders bar" for neutralising a ship's magnetism.

July 19, 1838. Pierre Louis Dulong died.—Dulong was director of studies at the Ecole Polytechnique, and in 1832 became one of the secretaries of the Paris Academy of Sciences. In 1819 with Petit he enunciated the law connecting the atomic weight of a substance with its specific heat.

July 19, 1882. Francis Maitland Balfour died.—Killed at the age of thirty-one when climbing Mont Blanc, Balfour had just been appointed to a newly created chair of animal morphology at Cambridge. His "Comparative Embryology" appeared in 1880–81.

July 20, 1819. John Playfair died.—An Edinburgh professor, Playfair's principal contribution to science was his "Illustrations of the Huttonian Theory of the Earth."

July 20, 1866. Georg Friedrich Bernhard Riemann died.—Successor of Dirichlet in the chair of mathematics at Göttingen, Riemann was one of the most profound mathematicians of his time. E. C. S.

Societies and Academies.

London.

Geological Society, June 22.—Mr. R. D. Oldham, president, in the chair.—Dr. C. T. **Trechmann** and L. F. **Spath**: The Jurassic of New Zealand. The Jurassic beds of New Zealand comprise an important set of sediments, probably 10,000 ft. in thickness, exposed at certain points extending over the length of the North and South Islands. They follow the Trias with apparently perfect conformity. The affinities of the fossils from the Lower Lias to the Upper Jurassic formations are with those occurring in the Jurassic of the Argentine Andes, Western Australia, the Sula Islands, the Spiti Shales of the Himalayas, and the Jurassic deposits of Kutch. Descriptions of New Zealand ammonites from the British Museum collections, notably a small fauna of typically Mediterranean aspect, which is referred to the Middle Lias, were given.—F. **Dixey**: The norite of Sierra Leone. The norite of Sierra Leone constitutes a complex of which the oldest and most important member is an olivine-norite. The complex forms the mountainous mass which, with a narrow coastal plane of Pleistocene sediments, makes up the Sierra Leone peninsula. The norite was intruded in the form of a huge stock; it has no marginal or basic modifications, while its junction with older rocks is obscured by the Pleistocene sediments. The complex is probably somewhat later than Pre-Cambrian in age. The main intrusion of norite was invaded in succession by minor intrusions of younger norites, norite-pegmatite, beerbachite, norite-aplite, and dolerite. Features of the older norite are well-developed flow-banding, a series of binary and ternary intergrowths of the common minerals, and metamorphism due to the minor intrusions. Iron-ores occur in the norite as small masses, narrow schlieren, and disseminated grains; they are highly titaniferous. Sulphides and other economic minerals are rare or absent.

Edinburgh.

Royal Society, July 4.—Prof. F. O. Bower, president, in the chair.—C. T. R. **Wilson**: Recent work on lightning and thunderstorms. A thundercloud may be regarded as a great electrical machine, and suggests such questions as the electromotive force developed by the machine, the current which passes through it, and the external distribution of the current. It is at present mainly from a study of the electric force at the ground during thunderstorms that we obtain information on these points. Records were shown of the changes in the electric field due to thunderstorms at a distance, and of the sudden changes produced by lightning discharges. From the results of automatic records of this kind it is concluded that in an average lightning flash a quantity of electricity amounting to about 20 coulombs passes, and that the potential difference required to cause the discharges is of the order of one thousand million volts. In addition to lightning discharges there may be considerable continuous currents maintained by the thundercloud. The electrical energy going to waste in a thunderstorm may amount to a million horse-power. A large part of the current maintained by the thundercloud may pass through the cloud from the ground to the conducting upper atmosphere, or from the upper atmosphere to the ground, and produce effects which are of importance in connection with the atmospheric electricity of fine weather, and possibly with terrestrial magnetism.—Prof. H. **Briggs**: The adsorption of gas under pressure. The author describes a series of experiments

with different gases and with different adsorptive substances to ascertain the volume of gas adsorbed at pressures up to 100 atmospheres. The tests show that it is possible to increase the gas capacity of a cylinder, holding the gas under compression, if the cylinder be completely filled with coconut charcoal before the gas is pumped in. The reason for certain sudden outbursts of fire-damp in coal mines is stated to be due to the adsorption of that gas under pressure by the coal. In some cases millions of cubic feet of fire-damp have been suddenly discharged in mines when the equilibrium was disturbed.—Miss Elizabeth **Gilchrist**: The utilisation of solid caustic soda and the absorption of carbon dioxide. The experiments aimed at ascertaining the optimum condition for the absorption of carbon dioxide by solid caustic soda granules, especially with the object of improving that action in mine rescue apparatus. The absorption diminishes at temperatures approaching 0° C. and at temperatures exceeding 100° C. The behaviour of a caustic granule at or near the optimum condition is described, it being shown how the granule swells gradually, eventually becoming a shell of carbonate hollow within.—Miss Augusta **Lamont**: The development of the feathers of the duck during the incubation period. The external appearance and the internal structure of the feather-papillæ are figured and described, and special stress is laid on the distinction between pennaceous and plumaceous feathers during their earliest stages. The work is preliminary to further researches.—A. G. **Ramage**: Note on the conditions for mirage on the Queensferry Road. The surface of the road was remade in the spring of 1919 with road metal and liberal supplies of bitumen, and small pieces of quartz scattered on the top of the bitumen, the whole being rolled by a steam-roller. After this had been done no signs of the mirage, so common on this road the previous summer, made their appearance until August, and then but faintly. During the summers of 1920 and 1921, on bright days, mirage was again much in evidence, showing that a newly made road is not conducive to the appearance of the mirage phenomenon.

Dublin.

Royal Dublin Society, June 28.—Dr. F. E. Hackett in the chair.—Prof. T. **Johnson** and Jane G. **Gilmore**: The occurrence of a Sequoia at Washing Bay, Co. Tyrone. The conifer was found in the core of the coal-bore, especially in the zone between 890–930 ft. It is represented by wood, by shoots showing dimorphic foliage, by cones and pollen-grains. The authors find it to agree in all respects with *S. Couttsiae*, Heer, from the upper Oligocene of Bovey Tracey, Devonshire. They have also examined Baily's type material of *S. du Noyeri*, and refer it to *S. Couttsiae* as a possible variety. They describe one specimen showing the two types of foliage on the same shoot. The paper also contains an account of the distribution and characters of the stomata in Sequoias, recent and fossil.—P. A. **Murphy**: The sources of infection of potato tubers with the blight fungus, *Phytophthora infestans*. The results of field experiments in Canada and Ireland on the decay caused by the blight fungus in potato tubers, with particular reference to the rot which sets in after digging, are detailed. When blight rot is found in quantity in the pits in winter it does not owe its origin to the spreading of the disease from a few initially infected tubers. Many tubers not visibly diseased carry the infection with them to the pits. The source of infection has been traced to contact of the tubers at digging time with blighted, but partially living, foliage, and with contaminated surface soil. The conidia live in the soil for at least two weeks after the death of the tops, and such soil may be a dangerous source of infection.

Paris.

Academy of Sciences, June 20.—M. Georges Lemoine in the chair.—H. **Andoyer**: The direct demonstration of a theorem of Tisserand relating to the development of the perturbation function.—E. **Haug**: The tectonic of the coast region between Saint-Cyr and Hyères.—C. **Richet**, Mlle. Eudonie **Bachrach**, and H. **Cardot**: The alternations between tolerance and anaphylaxy. Studies on the lactic ferment. Successive generations of the bacillus show at first a decrease in activity by small proportions of mercuric chloride in the culture media, then get accustomed and increase in activity (measured by the lactic acid formed), but lose this tolerance later, become sensitive, and are killed. With smaller doses of the poison there is at first an acceleration, then an anaphylactic phase, and finally death of the organism.—C. **Depéret** and M. **Solignac**: The Sahalian of northern Tunis.—M. **de Sparre**: The yield of turbines working with a variable head.—W. **Kilian** and F. **Blanchet**: The presence of a sub-alluvial sheet of thermal or mineralised water in the bed of the Durance, at Serre-Ponçon. These hot springs were discovered in the course of work carried out in connection with the construction of a hydro-electric power station. The water was saline, temperature 47° to 49° C.—B. **Gambier**: The deformation of surfaces and the Laplace equation.—L. **Dunoyer**: The complete chronophotographic determination of trajectories. The method is based on the simultaneous photography from two determined positions of the path of a luminous projectile.—A. **Sanfourche**: The absorption of the oxides of nitrogen by sulphuric and nitric acids.—L. **Guillet** and M. **Ballay**: Critical points due to hardening caused by wire-drawing. The hardened wire has a part annealed, and the electrical resistances of the annealed and unannealed portions are compared at various temperatures; the results are recorded on a differential curve. This electrical method is superior to the dilatometric and other methods in use.—A. C. **Vournazos**: A new magnesian hydraulic cement. A description of the preparation and properties of some cements produced from magnesia (magnesite calcined at a low temperature) and powdered pumice or silica. —M. **Baille-Barrelle**: Contribution to the study of the coking of Saar coals.—A. **Mailhe**: The catalytic decomposition of the polyhalogen derivatives of the paraffins. A study of the reduction of tetrachloroacetylene, tetrabromoacetylene, chlorodibromopropane, dichlorodibromoacetylene, and trichlorodibromoacetylene by hydrogen in presence of reduced nickel and barium chloride as catalysts. The product is always a halogen-substituted ethylene. When there are different halogens the bromine is first removed by the hydrogen.—J. B. **Senderens** and J. **Aboulenc**: The catalytic decomposition of the bromoacetic acids and of mixtures of bromine and acetic acid.—J. **Savornin**: Observations on the Palæozoic of Rabat, Morocco.—P. **Bonnet**: Mesocretaceous volcanic eruptions and their relations with the distribution of the facies in the Caucasian geosynclinals.—J. **Cvijić**: River platforms and erosion steps.—Mlle. Y. Boisse **de Black**: The "frane" of the Cère Valley.—A. **Treuthardt**: Some new measurements of the density of the air at Geneva. Some results of measurements carried out in 1917. The deviations observed are larger than the experimental error, and the values below the average (1·29269) were obtained when the barometric pressure was above the

mean pressure for Geneva.—E. **Moles**, T. **Batuccas**, and M. **Payà**: The density of the air at Madrid and its small variations. The results of thirty series of measurements are given, each series comprising two or three observations. The mean is 1·29303, and the deviations are regarded as being outside the experimental error. In agreement with the Loomis-Morley hypothesis, the minima of density correspond with the maximum of atmospheric pressure and conversely.—L. **Blaringhem**: The pollen of flax and the degenerescence of the varieties cultivated for the fibre. The study of the quality of the pollen of isolated pedigrees, followed during several generations, is recommended for the selection of flax grown for the fibre.—C. **Porcher** and A. **Chevallier**: The distribution of the saline substances and the mineral elements in milk.—W. **Mestrezat** and Mlle. S. **Ledebt**: The compensating *rôle* of chlorides in its relations with the chemical composition of the body fluids.—P. **Chailley-Bert**, R. **Faillie**, and J. P. **Langlois**: The "second wind" of runners. Experiments are given showing that the "second wind" is brought about by a diminution in the respiratory exchanges, and that this diminution, the work remaining constant, is the result of a better adaptation of the subject, an improvement in the yield of the human machine.—H. **Piéron**: The importance of the peripheral phase in the margin of the variation of the times of sensorial latency as a function of the intensities of stimulation.—A. **Vandel**: The question of cellular specificity in *Polycelis cornuta*.—F. **Picard**: The determination of egg-production in *Pimpla instigator*. Experiments proving that the sight plays no part in the act of depositing the egg.—P. **Remy**: The action of the vapours of chloropicrin on *Argas reflexus*. This parasite of the pigeon has proved to be extremely difficult to destroy by the ordinary insecticides; it is now proved to be destroyed by the vapours of chloropicrin, the amounts required being small enough for practical use.—A. **Goris** and A. **Liot**: Observations on the culture of the pyocyanic bacillus on artificially defined media.—E. **Sergent** and M. **Béguet**: The mycosic nature of a new disease of the date-palm threatening the Morocco oases.

SYDNEY.

Linnean Society of New South Wales, May 25.—Mr. G. A. Waterhouse, president, in the chair.—T. G. **Sloane**: Revisional notes on Australian Carabidæ, pt. vi. The tribe Bembidiini is reviewed so far as the Australian fauna is concerned. The synonymy is given, and seven species of Tachys are described as new. The tribe, as represented in Australia, consists of five genera, of which only Illaphanus is peculiar to Australia; the five genera comprise fifty-eight species.—Dr. A. J. **Turner**: Revision of Australian Lepidoptera—Hypsidæ, Anthelidæ. Six genera, one of which is new, and fourteen species of Hypsidæ and seven genera and forty-seven species (twelve new) of Anthelidæ are described.—T. **Steel**: Ulmite, a constituent of black sandstone. A black friable sandstone which outcrops frequently on the coast of New South Wales consists of sand grains with a thin, dark-coloured coating. This coating is identical with humus extracted from soil.—W. P. **Hiern**: A new species and a new variety of Diospyros. A new species is described from New Caledonia, and a new variety of *D. samoënsis* from Apia, Samoa.

The Tuberculosis Problem.

THE forthcoming international conference on tuberculosis, which is to be held in London on July 26–28, is likely to provide some considerable additions to our knowledge of this chief of diseases, and may, it is hoped, serve also to give heart to those engaged in the preventive and curative work which has stood the test of trial. The president of the International Union against Tuberculosis is the eminent French jurist and statesman, M. Léon Bourgeois, and it is significant of the double *rôle* of the conference that Prof. A. Calmette, of Lille, will open a discussion on the modes of diffusion of tuberculosis throughout the races of the world, while an English physician, Sir H. Rolleston, will open another discussion on the duty—too much neglected—of the medical profession in the prevention of tuberculosis.

On the first subject much additional light has been thrown by the investigations of Metchnikoff and of Prof. Calmette himself, and by the further evidence marshalled, a few months ago, in an interesting contribution by Prof. Cumming, of the University of Wales, to the *International Journal of Hygiene*. In a recent volume on "The Epidemiology of Pulmonary Tuberculosis," Col. Bushnell, of the U.S. Army Medical Service, who will take part in the London conference, has collected a mass of evidence on the racial incidence of tuberculosis, which enables us to approach to a definite understanding of the remarkable differences in the death-rate from tuberculosis in different races. Briefly and, therefore, imperfectly summarised, the general trend of facts indicates that the differences displayed between different races are largely, if not entirely, explicable by consideration of the age at which exposure to infection by tubercle bacilli first occurs, by the dosage of infection which is received, and by the social and sanitary circumstances in which populations are infected. There may be—and it is not improbable that there are—true racial differences in susceptibility to infection, due to the fact that certain races have not experienced the selective effect of exposure during many generations to infection. Nevertheless, although this factor cannot be excluded by any directly available evidence, it is scarcely consistent with its operation on a large scale that there exist remarkable differences in respect of mortality from tuberculosis between persons in various social strata and industrial occupations and between communities the members of which have all been exposed for many generations to the ravages of this disease.

Whatever view is taken of the selective influence of exposure to tuberculosis in successive generations, epidemiological facts show clearly that the amount of tuberculosis in adult negroes, for instance, is determined in large measure by their past individual experience in respect of exposure to the infection of this disease. In Army experience, negroes who have previously lived under urban conditions have had little more tuberculosis than white men under similar conditions. In the past much error has arisen from not comparing white and coloured populations of corresponding social status. Negroes commonly live in overcrowded houses, are badly fed, and are extremely dirty in their habits; comparison should therefore be between them and the occupants of common lodging-houses, rather than between them and the average white population.

When, however, negroes who have previously lived in remote parts where tuberculosis is not prevalent are exposed to infection, they suffer to an extraordinary extent. The same remarks apply to Red Indians and other races having a similar antecedent experience. This difference between persons not exposed in early life to infection and others who have been so exposed holds good, as is well known in Army experience, for measles. Adults, whether coloured or white, who have not previously been exposed to measles suffer much more severely from this disease than the average adult. In this instance, also, the

operation of natural selection is conceivable, but it may be that the *differentia* between the two classes lies in the acquired immunity due to attacks in early life, or to the vaccinal influence of small repeated doses of the specific contagium. There is little doubt, however, that at the forthcoming conference Prof. Calmette and others will marshal the evidence bearing on this and allied disputed points.

It is too little known that, even in a country like England, in which tuberculosis has long been endemic, the highest death-rate from this disease occurs during the first five years of life. In the first year after birth one death out of every twenty-six from all causes is certified to be due to tuberculosis; the real proportion is much higher, many deaths returned as due to pneumonia or bronchitis being cases of acute tuberculosis. Landouzy has stated that 27 per cent. of the deaths in the first two years of life are caused by tuberculosis. The practical lesson from these facts is that in childhood in every race there is but little resistance to the infection of this disease. If, therefore, the total human death-roll at all ages from tuberculosis is to be lowered, it is of supreme importance to prevent children from being exposed to infection during the first five years, and especially during the first two of these years.

The heavy child mortality from tuberculosis is followed by a lull in the incidence of the disease. Then there occurs a second peak of heavy mortality from tuberculosis in its pulmonary form, which in some communities is as high as, or even higher than, that in childhood. Dr. Brownlee has made some ingenious suggestions as to the reasons for the different ages at which this second peak reaches its maximum in various sections of the country, and it is to be hoped that this subject will receive adequate discussion at the forthcoming conference. Dr. Brownlee's suggestion that male adult-tuberculosis has a different origin, according to the shape of the curve, must be tested by the construction of similar curves of female mortality. Moreover, it remains to be shown that the varying age-incidence of maximum mortality from tuberculosis in different areas is not the result of varying exposure to infection and to circumstances calling latent tuberculosis into activity, rather than of a different etiology.

The double age curve of tuberculosis mortality in civilised urban communities throws light on the excessive mortality from tuberculosis among native races. In this country children who have received (and possibly continue to receive) small doses of infection not competent to produce active disease acquire a relative immunity, which is overcome only when irritating dust, excessive fatigue, alcoholism, or an acute illness lowers personal resistance to a dangerous point. There was ample experience of these causes of excessive tuberculosis during the Great War. If native races are not thus "salted" in early life, they suffer excessively when exposed to tuberculosis in later life. Hence, as already indicated, the importance of safeguarding young children against protracted exposure to infection, and in later life of the segregation of bedridden cases of tuberculosis and of other patients living in unhygienic circumstances. In addition there are general measures of hygiene and improved nutrition the value of which in reducing tuberculosis is beyond question.

The practical aspect of special tuberculosis work will doubtless be discussed from many points of view at the London conference. It is common ground that the notification of tuberculosis to the Medical Officer of Health is an indispensable link in the chain of preventive measures. Unfortunately, it is well known that notification is imperfectly carried out by a large proportion of medical practitioners, who often do not notify cases for several months after they have come under their care. Thus the possibility of the more active preventive measures necessary is delayed.

The general relationship of the private practitioner to the prevention of disease is of fundamental importance if rapid progress is to be made. How to harness him to public health work is perhaps the most difficult, as well as the most important, problem of State medicine. At present he is often a hinderer of progress, though in other instances he is the most valuable of State servants. This subject also will doubtless be discussed at the forthcoming conference.

It cannot be said that the medical machinery of the National Health Insurance Act has helped. When we recall the fact that, even in present circumstances, a panel doctor may sometimes have as many as 3000 insured persons on his list, for whom he receives the annual payment of 1650*l.*, while he is also allowed to take other private patients, it cannot be expected that the adequate examination of all suspected cases of tuberculosis and their early treatment can be satisfactorily undertaken.

The essential point to be realised in practice—

and we are far from this at present—is that we cannot expect complete success in anti-tuberculosis work until we are in a position to say that "we are exercising complete supervision over, and making provision for, the whole of the sick life of the consumptive, whether he is trending towards complete recovery or towards death." There is not a single community in Great Britain concerning which that statement can be affirmed. The nearest approach to it is what is known as the Framingham experiment, which has been going on for four or five years in a small town in Massachusetts, and of which a valuable account has been published by the American Tuberculosis Association. It is to be hoped that a full account of this experiment, and the results which have been obtained, will form part of the proceedings of the forthcoming conference in London.

The Foundations of Physics.

Physics: The Elements. By Dr. Norman R. Campbell. Pp. ix + 565. (Cambridge: At the University Press, 1920.) 40*s.* net.

DR. CAMPBELL has attempted with great courage a very ambitious task—that of discussing critically the fundamental conceptions, propositions, and methods of the science of physics. A rough idea of the nature of his work may be given by saying that he attempts to do for the foundations of physics what Peano, Whitehead, Russell, and others of the modern critical school have done for the central principles of mathematics. The spirit, however, rather than the exact method of these mathematical philosophers is what he emulates, for, apparently, one of the factors which determined him to write this book was a lively dissatisfaction caused by the fact that hitherto all inquiry of this nature in physics has been carried out by mathematicians rather than by experimenters. Mach, of course, in spite of Dr. Campbell's implication, was an experimenter of note, as well as a mathematician and philosopher, but our author aspires to a somewhat more complete and general discussion than that carried out by Mach for certain branches of physics, and wishes to include recent developments. Again, he is more anxious to win the confidence of the man in the laboratory (who, as he says, is often "not merely uninterested in fundamental criticism, but positively hostile to it"), while at the same time desiring to meet the logicians on their own ground, if not with their own weapons. From a window in his study he looks down with sympathy upon the laboratory, and writes with one eye on the bust of Mr. Bertrand Russell, serene above the conflict, and with the other on the working physicist, who is cursing alternately his electrometer and the theory of errors.

Dr. Campbell realises clearly that the physicist is not necessarily either logical or consistent when he is most efficient. This realisation is an important feature of the book, and distinguishes the author from his predecessors. "It is undoubted," he says, "that we can study science with perfect satisfaction to ourselves . . . although we commit the heinous offence of using ambiguous terms. And this fact is simply an indication that we do not use in the course of our study any processes which require words to be unambiguous." "Illogical is not synonymous with erroneous." Again, he insists more strongly upon the fundamental importance of analogy than do most writers on the principles of science, contending that analogies are not so much aids to the establishment of theories—the usual view—as essential parts of the theories. The theories are systematic expressions of analogies. Here, we think, he will not only interest all physicists, but also carry them with him. On the other hand, his discussion of such points as how we can define, say, silver, and his conclusion that all logical difficulties can be avoided by stating "silver exists," will not, possibly, appeal to the experimenter. The experimenter has never felt the need of a formal definition of his materials; Dr. Campbell agrees, but labours the point at considerable length, whereas the question of modern conceptions of isomers and isotopes, which will bear much discussion, receives little attention.

The book before us (the preface informs us that further volumes have been contemplated) is divided into two parts, one dealing with the propositions of science, and the other with measurement. The first consists in the main of a discussion of the nature of laws, hypotheses, and theories, of what is meant in physics by these terms, and of the possibility of obtaining more or less formal definitions of them. Dr. Campbell's debating often tends to show the difficulty of arriving at conclusions rather than to lead us to convincing conclusions—a fact attributable to the difficulty of the subject. For instance, he suggests that the decision as to whether a given proposition is or is not a law has to be left to the judgment of serious students of science—which is sound, but not sensational. Throughout the book the word "important" plays a large part, and obviously to reduce a question to terms of relative importance is to raise fresh points. The discussion of

theories, comparing as it does, in particular, the services of mechanical and mathematical theories, is of great interest. The aspect of a theory brought out so strongly by Mendeléeff's words, "By a theory I mean a conclusion drawn from the accumulated facts we now possess which enables us to foresee new facts which we do not yet know," might, perhaps, have been more emphasised.

Of Mill's canons of induction our author disposes in a very workmanlike manner. The chapter on chance and probability seems to us to contain some very sound and valuable remarks on the fundamental assumptions of this difficult study. An example in this chapter has already drawn down the wrath of an eminent mathematician; this example, which deals with the drawing of a given ace from a piquet and a whist pack side by side, at first sight appears to be made the ground of a somewhat perverse comment on ordinary reasoning, since it is admitted that the ordinary estimate of the probability is "right"; but actually it leads up to a point of some importance. The usual assumption is that the choice of either pack in the first instance is equally probable; but this does not follow from first principles unless further conditions as to blindfolding, and so on, are introduced. Actually, the chooser might well be considerably influenced in his choice by the relative size of the packs; and what is really the probability of drawing a given ace is a matter for experiment under conditions rigorously specified. The point brought out, though perhaps not that on which most stress is laid, is that the given conditions are often not stated precisely enough in problems of this nature.

The discussion on probability is continued in the second part, where the subject of errors of measurement is investigated. The criticism here is searching, but is not likely to be accepted in its entirety without debate: the suggestion that the physicist will more frequently find distributions in his notebooks which give a curve like the letter "A" with its top removed than a Gaussian curve will scarcely be accepted. No doubt his arguments will receive more detailed consideration from the experts than is possible here.

The chapter on units and dimensions deserves particular attention. It contains valuable observations on no-dimensional magnitudes and formal constants, as well as some startling suggestions, including what seems to be an implication that the arrangement of the terms in a dimensional equation is of importance.

Dr. Campbell writes with enthusiasm and seeks the combat where it is thickest. The chief fault of his style arises from a desire to deal with every possible comment that might be raised and hence to labour points which are sufficiently obvious. There is a certain lack of co-ordination, which he acknowledges; in fact, one of the things which render it an ungracious task to criticise is that the author is keenly alive to deficiencies in the book, and is always anxious to point them out himself. The work gives the impression of brilliant and informed table-talk on the basis of physics carried on evening after evening, the amount of thought devoted to any particular point depending largely on the mood of the moment. There is little doubt that most readers will find Dr. Campbell provocative in parts, but, whatever else he may provoke, he provokes thought. Finally, it is a great feat to have assembled so much interesting matter, and to have put together a book containing so much fresh thought on a subject of fundamental interest. It is to be hoped that the interest taken in this book will prove amply sufficient to encourage the author to bring out the contemplated remainder of the treatise.

E. N. DA C. ANDRADE.

Mind and Brain.

In Search of the Soul and the Mechanism of Thought, Emotion, and Conduct. By Dr. B. Hollander. Vol. i.: *The History of Philosophy and Science from Ancient Times to the Present Day.* Pp. x+516. Vol. ii.: *The Origin of the Mental Capacities and Dispositions of Man and their Normal, Abnormal, and Supernormal Manifestations.* Pp. vii+361. (London: Kegan Paul, Trench, Trubner, and Co., Ltd.; New York: E. P. Dutton and Co., n.d.) 2*l*. 2*s*. net two vols.

THAT the psychological phenomena loosely grouped together under the term "mind" are in some way correlated with the physiological activities of the brain is a proposition which may be regarded as having been generally accepted for more than a century past; the question, however, as to what is the nature of that correlation still remains unsolved. The fact that this particular question must be allowed to lie in abeyance does not militate against the very legitimate attempt to locate differentiated mental functions in relation to the various structural parts of the brain, and as a matter of course many observers have sought to produce a psycho-physiology of the brain.

The human brain is chiefly remarkable, from the point of view of comparative anatomy, for the extraordinary development of the cerebral hemispheres, which conceal practically all the other portions of the brain. They constitute virtually a great pall consisting of a grey surface or cortex, composed of many layers of innumerable nerve-

cells, and a white medulla or stalk, composed of millions of nerve-fibres which connect the cortical cells with one another, with other structures in the brain, and with the body tissues generally. Conceive this mantle with a surface divided up by a very constant pattern of grooves and elevations the marvellously complex and unique structure of which had just come to light; then, bearing in mind the "faculty" psychology which was generally held a century ago, it is easy to comprehend the high hopes entertained and the attempts that were made to parcel out the faculties on to the surface so naturally prepared. From these attempts to localise the higher mental functions before the nature of cerebral physiology was at all understood arose the cult of phrenology and all the charlatanism to which it gave rise.

To the serious student, phrenology, the lore of telling the character from the prominences of the skull, became quickly discredited because it was obvious that, as the thickness of the skull bones varied irregularly, the external configuration of the skull bore no definite relation to the surface of the brain underneath. This circumstance did not interfere with the followers of the mental localisation theory, but they themselves soon began to experience difficulties of their own. To obtain any agreement on the matter of localisation, it was first of all necessary that each observer should hold precisely the same views as to the division of the mind into faculties, and this essential preliminary gave rise to much difficulty, because very few persons were agreed on the subject. Many schemes were propounded and much argument took place until it was seen that, from the purely psychological point of view, the "faculty" conception of psychology was untenable. From regarding, for instance, the quality of aggressiveness as a separate entity, the opinion was formed that it was a trend of the personality as a whole. Moreover, the independent experiments of the physiologists and the observations of the neurologists began to take definite shape, quite apart from the speculations of the philosophical psychologists.

A great deal of knowledge has now accumulated, and modern opinion, which is supported by the vast amount of detail derived from the many cases of head injury in the war, is very definitely against any possible cortical localisation of separate mental faculties. The modern theory is embraced by the broad statement that the cortex is to be considered as a vast associational mechanism functioning as a whole, the chief purpose of which is one of inhibition of the lower activities of the nervous system; in other words, it is the mechanism whereby a considered intellectual activity is substituted for an emotional reflexive type of reaction to environment. The cortex contains the termini of the various sensory streams of nerve-fibres arising in all parts of the body, and also the origin of the motor nerve-fibres going out to the muscles of the body. Apart from these connections, which have now been mapped with fair accuracy and are termed the sensory and motor areas respectively, there is no question of there being any real mental localisation. If the cortex be injured outside one of these areas, the individual becomes generally irritable or lacks control, and at the same time loses to a certain extent the capacity for intellectual thought.

Dr. Hollander, so one gathers from his book, does not agree with modern opinions. He prefers to stand by the old "faculty" psychology and the corresponding physiological ideas, and he has produced a monumental work in support of his views. In the very interesting first volume of his book he takes the reader right from the beginning of recorded philosophical speculation up to present-day knowledge of the mind and brain, extracts being given from and personal references made to practically every writer on the subjects under discussion. This mass of information, collated with a care that the reader will appreciate, must have involved a tremendous literary research and labour. It is only marred by the fact that the author stresses or belittles the facts to so great an extent in the effort to establish his point. His defence of the physiologist Gall, who was one of the first to take up the matter of cerebral localisation, is masterly; so much so that one sighs that such energy, ingenuity, and thought should have been expended in the resuscitation of a bygone stage of knowledge when there is so much new ground to be explored.

The second volume is disappointing. Here we have Dr. Hollander's views on many things; too many things really to be included within the same cover. A considerable portion of this volume is devoted to the development of his argument on behalf of the cerebral localisation of mental function, and to this end he lays down his psychology, which is of the faculty type and singularly lacking in reference to the most recent developments; *e.g.* there is no mention of such illuminating conceptions as that of the defence mechanisms or of the influence of the sympathetic and endocrine systems upon the mind. His treatment of the question of insanity is in the style of a very commonplace abridged text-book, not at all what one would have expected in a book of this kind; while some of his statements, though they may safely be left to the judgment of the

professional reader, require a little criticism for the benefit of the layman in these matters.

Dr. Hollander, like all enthusiasts, is inclined to lay the onus of failure of vision on those who do not agree with him. He disposes of his opponents on the ground that they do not follow out his system; but he must realise that some of the greatest intellects in science have been busy on these problems, and that they cannot all be wrong and only he be right. He must give a little credit to the labours of such men as Sir Frederick Mott, Sir Victor Horsley, and many others one might mention. Again, the difficulty the physicians of our mental hospitals have to face is not the fact that they are not allowed to fulfil their duty—they have every opportunity to do that in the very efficient and well-equipped modern mental hospital—but the attitude of the friends and relatives of the mental patient who, for sentimental reasons, oppose any effort to place the patient under proper care in the early stages of the disorder. As regards the question of treatment, of course everyone is entitled to whatever opinion he chooses, but it may be as well to point out that the consensus of modern opinion is that the day has not yet dawned when mental disorder can be treated by the surgeon. In a few cases of very definite brain injury an operation might be considered, but, even so, it is often found that the patient's last state is no better than the first.

Space does not permit of any detailed criticism of the remaining chapters of the book; it must suffice to say that the author passes on from criminology to thought reading and allied subjects, and ends upon a metaphysical note. The book is well written and well arranged; every credit must be given for the truly immense labour involved in its compilation; but it is to be feared that it is too much out of joint with the times to exercise much effect on the opinion of the day on these matters.

Mineralogy for Students.

(1) *Economic Mineralogy: A Practical Guide to the Study of Useful Minerals.* By T. Crook. Pp. xi+492. (London: Longmans, Green, and Co., 1921.) 25*s.* net.

(2) *Mineralogy: An Introduction to the Study of Minerals and Crystals.* By Prof. E. H. Kraus and Dr. W. F. Hunt. Pp. xiv+561. (New York and London: McGraw-Hill Book Co., Inc., 1920.) 27*s.*

EACH of these books is intended both as a text-book for students and as a work of reference for practical men.

(1) In Mr. Crook's case the reader has the advantage of his life-long employment on the economic investigation of minerals, while his experience as a lecturer enables him to appreciate the difficulties of the beginner. He carefully avoids unnecessary excursions into theoretical considerations, but his explanations, so far as they extend, are exceptionally clear and simple. He gives considerable attention to the optical examination of crystals, on account of its value in recognising minerals; and there is a helpful chapter on the use of the blowpipe and chemical methods generally. Another chapter is concerned with the physical analysis of crushed rocks and loose detrital sediments, a subject that the author has made peculiarly his own; and the short account of the geology of mineral deposits should be of use to the prospector.

The greater portion of the book is, however, devoted to a detailed description of the minerals of practical importance. The arrangement and treatment are frankly based on economic considerations, which should be a recommendation to all who are engaged in the commercial development of mineral resources. Moreover, Mr. Crook does not confine his attention to minerals in the strictly scientific meaning of the word, but includes all that is covered by the legal and technical definition of the term—everything which is mined for its economic value—so that coal, asphalt, and petroleum find their place in his survey. He also deals briefly with building materials and road metal. The volume concludes with some useful determinative tables, which are set out in such a manner that it is possible to glance rapidly through them in search of the information required. The text is illustrated by clear diagrams, and by excellent photographs of minerals taken by the author himself.

(2) Prof. Kraus and Dr. Hunt present us with a treatise of a somewhat more elaborate character, largely compiled from previous publications of one or both of the authors. Considerable attention is devoted to crystallography, and there are detailed tables for determining minerals. In the general description of the commoner minerals they are arranged according to the usual chemical classification, but there is a separate chapter on gem-stones, and another in which the minerals are classified according to the elements to which they owe their economic value. Monazite, however, appears in this section under cerium, which, although present in considerable amount, is of little commercial importance, instead of under thorium, for which it is almost exclusively worked. The use of tetra- (instead of tetarto-) in referring to a quarter-pyramid in the triclinic

system should be corrected in another edition, as should also a few misprints (especially on p. 319). These are, however, matters of minor importance.

Taken as a whole, the book appears to be carefully and attractively written, and is illustrated by photographs of both minerals and crystal models, though it is doubtful whether the latter are really more effective than the line drawings that accompany them. There are also photographs of distinguished mineralogists, past and present, but a *caveat* must be entered to the claim that Werner was the first to place mineralogy on a scientific basis. The credit of the foundation of the science must be shared by some of his predecessors, such as Cronstedt, as well as by contemporaries like Kirwan.

JOHN W. EVANS.

Our Bookshelf.

Elements of the Mathematical Theory of Electricity and Magnetism. By Sir J. J. Thomson. Fifth edition. Pp. viii+410. (Cambridge: At the University Press, 1921.) 30*s.* net.

EARLIER editions of this book were fully reviewed in NATURE, but the alterations and improvements in the present edition deserve special notice. One change—that in the treatment of hysteresis—makes the subject of energy dissipated in the magnetic field much clearer to the student. A piece of iron is put through a magnetic cycle and it is imagined as being displaced from one position in the field to another. The thing emphasised is the work done in effecting a displacement of a magnetic element in the field, which is $la I \delta H$, where H is the field intensity, I the intensity of magnetisation, and la the volume of the element. The former way of putting the matter puzzled the thoughtful student, while the thoughtless person accepted it without analysis of its meaning. It was said that "the diminution in the potential energy when the magnet moves into the stronger field is $Ial\delta H$." The change in potential energy was not this, but $la(I\delta H + H\delta I)$, and the thinker naturally wondered what had become of the term $la H\delta I$.

The most natural and convincing method of considering this matter is that due to the late Dr. John Hopkinson, and given when an attempt was made (not in this book) to demonstrate the hysteresis formula by juggling with the terms of the variation of a perfect differential. This method of Hopkinson's is to be found on p. 339. It considers the work thrown into the field from the battery when the magnetisation is changed by a magnetising current.

An interesting discussion of a gas the molecules of which are small magnets has also been added.

On the whole this edition of a sound and popular book is brought well up to date. All the alterations will be thoroughly appreciated by the student except that in the price, which has made a prodigious leap. It is a difficult time, as everyone knows, but many a student who would have willingly added this book to his own little stock of standard works will have to content himself with borrowing it.

A. GRAY.

Metabolism and Growth from Birth to Puberty. By F. G. Benedict and F. B. Talbot. (Publication No. 302.) Pp. vi+213. (Washington: The Carnegie Institution of Washington, 1921.)

BENEDICT and Talbot's work on the "Metabolism and Growth from Birth to Puberty" of children of both sexes aged from one week up to fifteen years is a continuation of that on new-born infants published six years ago. The children were all physiologically normal, and some of the data are from the same children at different ages. Measurements of the weight, height, pulse-rate, and body-temperature are recorded, as well as the basal metabolism figures—*i.e.* the heat evolved in twenty-four hours in the subject at quiet repose and in the post-absorptive condition. These conditions were not easy to attain in the case of infants; there was not usually quiet repose unless some food was in the alimentary tract, but occasionally measurements were made as long as nine hours after a meal. The data are thus rather above the real basal figures than below. The basal metabolism is referred to age, weight, height, and body surface in a series of curves. The body surface was calculated by the Du Bois formula from actual measurements. Weight and height run parallel with age, and the basal metabolism increased from approximately 150 to 1100 Calories. In comparison with body surface the basal metabolism rose rapidly during the first year; after this age there was a continual decrease. There was no marked difference between the sexes, but after reaching the weight of 11 kilograms boys had a slightly higher metabolism than girls. All the data for basal metabolism are lower than those recorded by previous investigators. The publication is a valuable contribution to physiological literature.

Chemistry. By G. H. J. Adlam. ("Science for All" Series.) Pp. x+238. (London: John Murray, 1921.) 3*s.* 6*d.* net.

THE book under notice is intended for a beginner who is "guided and inspired by a competent teacher." Many recent discoveries are included and the material is, on the whole, presented in an accurate and readable form. Several minor errors are, however, noticeable. Glaziers' "diamonds" are not "splinters" (p. 110); oxygen is not used in determining the flash-point of an oil (p. 119); the experiment described on p. 157 seems unlikely to succeed; the recovery of sulphur from alkali-waste is not without value (p. 170); and the carbon arc is not used in the fixation of nitrogen (p. 184). The atomic theory is explained only at the end of the book, although the method of counting the α-particles expelled from radium is referred to on p. 10.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Radiation from the Carbon Arc.

AN application of Merton and Nicholson's form of the wedge method has been made to the study of the intensity distribution in typical stellar spectra. In the late type spectra (including the sun), which are sufficiently bright at the red end, the energy curves give a marked depression from 0·50–0·67μ—a result not obtained by other observers. As the spectrum of the carbon arc, assumed to radiate as a black body at a temperature of 3750° Abs., is used to remove the colour curve of the plate, a possible cause of this depression, which is common to all stellar spectra that have been observed in the red, would lie in an intensity distribution in the carbon arc differing from that assumed.

In order to determine the intensity distribution in the spectrum of the positive crater of the carbon arc, the acetylene flame was used as a standard. The intensity distribution in a cylindrical flame of specified dimensions burning acetylene generated from commercial calcium carbide has been carefully determined by Coblentz with the bolometer (Bureau of Standards, Scientific Papers No. 279, 1916, and No. 362, 1920). To reproduce as closely as possible the conditions employed by Coblentz, a burner was used giving a cylindrical flame of the specified dimensions, and the acetylene used was obtained from three different sources: two cylinders containing acetylene compressed in acetone and a simple gasometer which generated gas from commercial calcium carbide. From 0·40–0·60μ the intensity distributions in the flames from these three sources were in good agreement. From 0·60–0·675μ there were systematic differences with a range of 8 per cent., due probably to the varying quality of the acetylene. In this part of the spectrum mean intensities were used as giving the closest approximation to Coblentz's conditions. Some initial experimental difficulties were encountered owing to non-uniform illumination of the wedge by the flame which could not be detected by the usual methods. It was found that reversal of the wedge on the slit furnished a very sensitive test of uniformity, and by the use of this method an arrangement of apparatus was secured which gave uniformity of illumination within the limits of the accidental errors of the wedge method.

When the initial difficulties had been overcome a series of eight spectra of the acetylene flame was obtained on Ilford panchromatic plates. At the same time five spectra of the positive crater of the carbon arc were secured, cored carbons being used with a current of 5·7 amperes. The heights of these wedge spectra were measured to two different densities at various wave-lengths by means of a simple form of microphotometer devised for that purpose. The two series of measures differed by less than 2 per cent. The final mean absolute intensities of the carbon arc for various wave-lengths are shown in Fig. 1 by black circles. The mean probable error of these intensities is 1·7 per cent., the mean probable error of a single plate being 5·7 per cent. These mean probable errors would be considerably reduced if the intensity at 0·675μ were not used, the intensity at this point being subject to large accidental errors on account of the rapidly changing colour-curve of the plate.

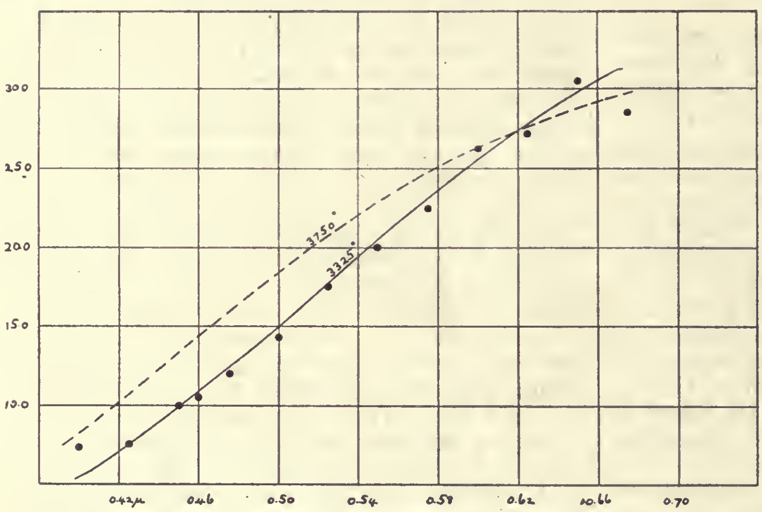

FIG. 1.—Intensity distribution in spectrum of positive crater carbon arc.

It will be noticed that the observed intensities depart considerably from the intensities computed on the assumption of black-body radiation at a temperature of 3750° Abs. (shown by the dotted curve). The use of the observed values of the intensity distribution gives results for stellar spectra more in accord with those obtained by previous observers. There is still outstanding, however, in the case of the sun a depression requiring further investigation.

Two hypotheses may be advanced to account for the observed intensity distribution:—

(1) The carbon arc radiates as a black body at a temperature of 3750° Abs., but there is an absorption band with its centre at 0·50μ, due possibly to the incandescent carbon particles in the arc flame. Coblentz has shown that at 2360° Abs. these carbon particles have an absorption band with centre at 0·60μ (Bureau of Standards, Scientific Paper No. 156, 1911). At the temperature of the arc flame this absorption band would suffer a shift to the violet, bringing its centre approximately in the observed place. The advantage of this hypothesis is that it is in accord with previous determinations of the arc temperature by such various methods as (*a*) the calorimetric method used by Violle, (*b*) the wave-length of maximum energy used by Lummer and Pringsheim, (*c*) Féry's determination from the total radiation, and (*d*) various determinations by optical pyrometers using an approximately monochromatic band in the red. This hypothesis is represented graphically in Fig. 1 by the dotted curve showing the intensity distribution of a black body at 3750° Abs. computed from Wien's law, so as to bring it into approximate agreement with the observed values from 0·600–0·675μ.

(2) The carbon arc radiates as a black body at a temperature of 3325° Abs. This hypothesis is represented by the full curve in Fig. 1, which fits the observed values fairly well. It can be brought into accord with previous work only by supposing that the commercial cored carbons used burned at a lower temperature than those carbons used by other investigators. Wanner has found differences of 200° depending upon the carbons used.

It is evident, if the carbon arc is to be used as a standard of intensity distribution for photographic spectrophotometry—and it is a very convenient standard—that its intensity distribution should be very carefully determined against a laboratory black body.

The Discovery of Large Quartzite Implements of Rostro-carinate and Early Palæolithic Types in Uganda.

THROUGH the kindness of Mr. E. J. Wayland, of the Geological Department, Entebbe, Uganda, I have become acquainted with an important discovery, made by him in Uganda, of a considerable number of large quartzite implements of rostro-carinate and Early Palæolithic types. Mr. Wayland has asked me to publish my opinion of the cultural relationship of the specimens, of which he sends me drawings, to the beak-shaped implements found beneath the Red Crag of East Anglia, and I may say at once that there would seem to be little doubt that the latter, though possibly more ancient, are clearly "related" to the East African artefacts.

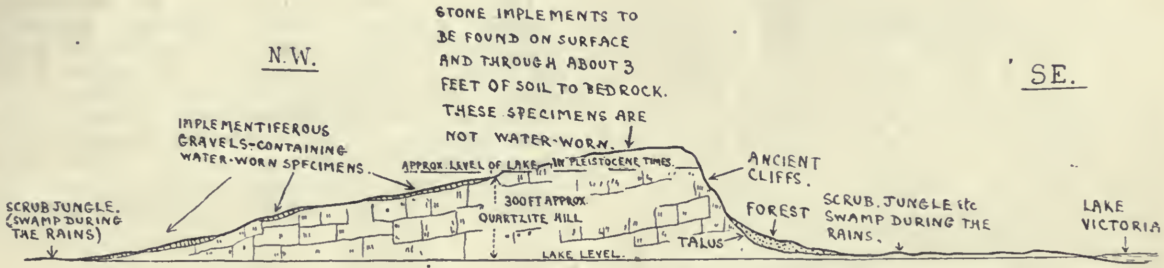

FIG. 1.—Rough diagrammatic sections (not drawn to scale) through Msozi Hill, Sango Bay, Buddu, Uganda.

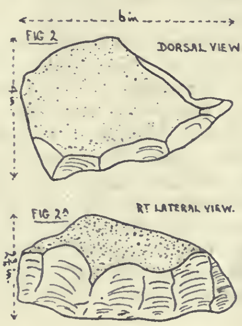
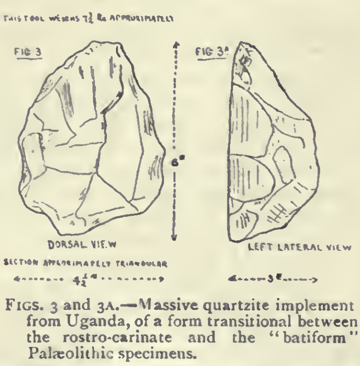
The exact localities where these new discoveries have been made are: (*a*) on the slopes and upon the summit of Msozi Hill, Sango Bay, Buddu, Uganda, and (*b*) at Kisiba, Tanganyika Territory. The accompanying diagrammatic cross-section (Fig. 1), copied from the drawing sent to me by Mr. Wayland, will make clear the positions in which the quartzite implements of Msozi Hill are found, and explain their discoverer's views as to the geological age of the specimens. As will be seen from an examination of Fig. 1, there are deposits of gravel on the slopes of Msozi Hill ("Quartzite Hill" of diagram) containing water-worn implements. On the summit of the hill, however, no gravel occurs, but Mr. Wayland finds upon the surface, and scattered through about 3 ft., of the soil, which there covers the bedrock, a number of specimens (of the same types as those found in the gravel) which are not water-worn. He observes, further, that the surface of Lake Victoria (shown to the right in Fig. 1) now rests at, approximately, 300 ft. lower than the level at which the unrolled implements occur, and he draws the conclusion that, when the people lived who fashioned the implements he has found, "Lake Victoria was 300 ft. above its present altitude, a state of things which, according to my showing, obtained during the Pleistocene Glacial period." It is thus clear that Mr. Wayland regards the quartzite specimens with which this letter deals as of considerable geological antiquity, a conclusion which, in my judgment, appears to be sound and in accord with the evidence he puts forward. From the numerous drawings of implements which have been sent to me, I have selected five which, while being representative of the majority of the implements figured, will, I think, enable me to fulfil Mr. Wayland's request that I should demonstrate the relationship of the Uganda specimens to the sub-Crag rostro-carinates of East Anglia.

The implement illustrated in Figs. 2 and 2A is, without any question, similar to many which have been found in the sub-Crag detritus-bed, and exhibits the characteristics of a broad, low rostro-carinate of primitive form, in which the keel, or carina, does not extend far back towards the posterior region of the specimen (Fig. 2A), and the dorsal surface (Fig. 2) is composed of unflaked "cortex." Figs. 3 and 3A illustrate a massive specimen—weighing approximately $7\frac{3}{4}$ lb.—which is somewhat similar in form to the



FIGS. 2 and 2A.—Rostro-carinate implement in quartzite, from Uganda.

implement just described. As will be noticed, the more or less flat ventral surface, together with the

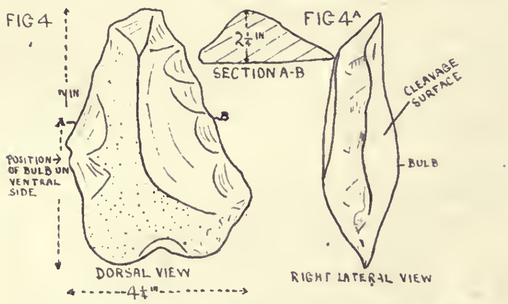


FIGS. 3 and 3A.—Massive quartzite implement from Uganda, of a form transitional between the rostro-carinate and the "batiform" Palæolithic specimens.

profile of the rostro-carinate form (Fig. 3A), is retained, but the dorsal surface (Fig. 3) is composed

almost entirely of flake-scars, while the keel, or carina, is not a very marked feature.

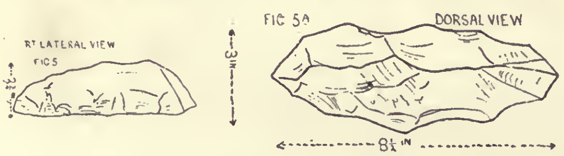
The implement illustrated in Figs. 4 and 4A is quite comparable, in its general outline and form, with that shown in Figs. 3 and 3A. Both these specimens, made from "chunks" of quartzite struck from still larger masses, are of great interest and importance as showing a transitional stage between the typical rostro-carinate form, with its prominent and functional keel, and the "batiform" Palæolithic implement, in which, while the simple triangular section is retained, the keel has become "depressed" and almost obliterated, thus ceasing to have any functional purpose. I have already described how, by the gradual "depression" of the carina, the rostro-



FIGS. 4 and 4A.—Massive quartzite implement from Uganda, of a form transitional between the rostro-carinate and the "batiform" Palæolithic specimens.

carinate developed into the "batiform" implement of Early Palæolithic times (Phil. Trans., series B, vol. ccix., 1920).

The specimen illustrated in Figs. 5 and 5A represents another form of the rostro-carinate, in which the keel extends continuously, and approximately, in the middle line, from the anterior to the posterior region of the dorsal surface. I have suggested in my Phil. Trans. paper that such specimens might have been used as "side-choppers," the more or less flat ventral area resting against the palm of the hand, while the prepared keel would be utilised as a cutting edge. It is, of course, possible that, in addition to such use, implements of the type shown in Figs. 5 and 5A might be used as picks. Figs. 6, 6A, and 6B illus-

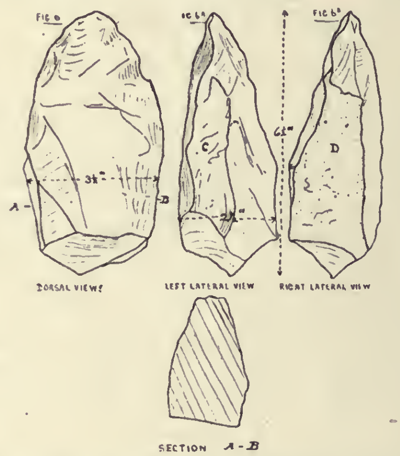


FIGS. 5 and 5A.—Quartzite implement of rostro-carinate form from Uganda, in which the keel extends over the whole length of the dorsal surface.

trate a specimen of well-known Early Palæolithic type, to which, at the suggestion of Sir Ray Lankester, I have given the descriptive name "platessiform." In this form of implement, in which the keel of the rostro-carinate becomes one of the cutting edges, while the more or less flat ventral surface is flaked away to form another cutting edge opposite to the keel (Phil. Trans., series B, vol. ccix., 1920), the method of manufacture is entirely different from that adopted in the making of a "batiform" implement. In the former the specimen is, as was pointed out by Sir Ray Lankester, so to speak, *compressed* from side to side, and the keel retained as a leading feature in its development, while in the latter the implement is, as it were, *depressed*—from above downwards—and the keel becomes functionless. The specimen illustrated (Figs. 6, 6A, and 6B) is of interest as showing, as do so many Early Chellean implements of similar form found in this country, the retention of portions of the original striking platforms (C and D in Figs. 6A and 6B), the dorsal and ventral surfaces of the ancestral rostro-carinate form.

From the above description it will be seen that I am of opinion that the specimens found by Mr. Wayland in Uganda are "related" to the rostro-carinate implements found beneath the Red Crag of East Anglia. It is clear, also, that the method of manufacture adopted in the case of these Uganda specimens is the same as was followed by the Early Chellean people living in this part of the world, and described by me in the Phil. Trans. paper quoted above.

The large collection made by Mr. Wayland in Uganda comprises certain well-made hand-axes, scrapers, and other forms of implements, of which, no doubt, a detailed description will appear in due course. But the majority of the relics found are, it seems, massive examples of Early Palæolithic artefacts, which appear to me to be very similar, in their forms, size, and technique, to those recently found by me at Cromer (NATURE, February 10, 1921). Mr. Wayland is to be warmly congratulated upon the



FIGS. 6, 6A, and 6B.—Quartzite implement of Early Palæolithic "platessiform" type from Uganda, showing portions of the original striking platforms retained (C and D in Figs. 6A and 6B).

important discovery he has made, which throws a new and welcome light upon the antiquity of man in Uganda. The outlines of the implements figured are not drawn to any special scale, but the approximate dimensions are indicated by the side of each drawing.

Measuring with High Powers of the Microscope.

UNDER a high power it is extremely troublesome to move the object so that one of its boundaries coincides exactly with a division of the micrometer-scale. But when the object is small this very greatly increases the accuracy; otherwise two estimated fractions of a division may constitute the greater part of the length measured.

Coincidence may be effected easily and with great exactness by gentle lateral pressure from the tip of the finger on the tube of the microscope; in this way the boundary of a well-defined image can easily be made to bisect a black line on the micrometer. If a

micrometer with lines 60μ apart be used over a 2-mm. objective with No. 8 eyepiece, each division represents 0.7μ, and a fifth part of a division corresponds to only 1/175,000th of an inch on the slide, which is therefore at the tube's centre the extent of the necessary distortion for bracket and bearing. The original position is recovered completely when pressure is removed. Probably everyone who uses high powers of wide angle has acquired the habit of effecting similarly extremely fine adjustments of focus by pressure on the stage.

With a lower power it is often helpful to press slightly on the nosepiece instead of moving the slide. For quick, rough measurements in the course of other work Prof. Dixon's "ghost micrometer" is very valuable (my friend Dr. W. R. G. Atkins introduced me to it). When the light is taken from a window the image of a piece of wire-gauze leaning against the pane can be brought on the object by a turn of the mirror, and removed again without losing sight of the object.

It may be worth adding that in measuring a distance in the line of sight (thickness) by the scale on the fine adjustment, one notch of the milling on the fine-adjustment head corresponds in my Zeiss to 1/10th of a division, or to 1μ (1.5μ with a dry objective). The notches can be read opposite the pointer through a lens, with a probable total error of 0.4μ for the single measurement of thickness.

In measuring the width or thickness of a calcite spicule the optic axis of which is parallel to the plane of the slide, or in examining an object above or below the spicule, greater accuracy can be obtained by placing on the ocular a Nicol with the plane of polarisation at right angles to the optic axis of the spicule, so that the high refraction of the ordinary ray is abolished. Ebner (*S. B. Ak. Wiss.*, Vienna, vol. xcv., p. 73) recommended to spongologists the use of the single Nicol for determining the direction of the optic axis of spicules.

Interference-colours between Nicols.—The measurement of thickness in these sponge-spicules is very difficult, and I hope to substitute for it the mere reading of the spicule's colour between Nicols. Empirically, the colour of all but the two "limbs" of the cylinder appears to be closely that of a calcite plate of equal thickness, and to be irrespective of the angular aperture of the objective (0·20 to 1·40) and of the presence or absence of an Abbe condenser between the polariser and the object. These are, to me, unexpected results in view of the much longer path in the spicule taken by the ordinary ray as compared with the almost unrefracted extraordinary ray. As it is difficult to exclude a 5 per cent. error from determinations of either the thickness or the retardation, and as it has been disputed whether the carbonate of lime in a spicule be wholly calcite, I shall be very grateful if a physicist will supply the theory of the colour of a cylinder (elliptical or circular) of calcite in Canada balsam. The diameter of the cylinder ranges upwards from a wavelength of light to 10μ or so; the lowest Δ I have determined accurately is $134 \pm 4\mu\mu$ for the middle band of a spicule, which is a right cylinder since its optic axis is parallel to its length, and the width of which is $830 \pm 40\mu\mu$.

Ocean Tides.

IN the letter in NATURE of May 26 (p. 393) under the above heading, by Mr. H. A. Marmer, of the U.S. Coast and Geodetic Survey, it is pointed out that tidal observations would be greatly enhanced in value if permanent bench-marks were established in connection with them, not only for the correlation of any future tidal observations at the same places, but also for the determination of the rate of elevation or subsidence of the land relatively to the sea.

It may be of interest to note that this question was taken up some fifteen years ago by the Academy of Sciences of Paris, when a prize was offered for the best determinations of mean sea-level from tidal observations in any country bordering on the North Atlantic as a basis for such relative change in elevation on its coast-line. This prize was awarded to the present writer as superintendent of the Survey of Tides and Currents in Canada, as it was found that we had already tidal data available for this purpose, because referred to permanent bench-marks, on an extent of eight degrees of latitude from southern Nova Scotia to Belle Isle Strait.

Although this survey was primarily organised in the interests of navigation, its practice of establishing local bench-marks from the outset in 1894 is also bearing fruit in other directions. It has afforded to the Geodetic Survey of Canada, more recently organised, determinations of mean sea-level on both Atlantic and Pacific coasts as a basis ready to hand for extended levelling throughout Canada. Our Geological Survey also refers its contoured maps to mean sea-level, and in several regions it has been possible to give that survey an independent starting-point for these contours from tidal observations already obtained at a locality in the region, as they were referred to a local bench-mark.

As it is not often that the same superintendent remains in charge of a survey for so long as twenty-seven years, it may be allowable to give these examples in our experience of the advantages of the practice recommended by Mr. Marmer, which may accrue years afterwards.

W. BELL DAWSON.

Ottawa, Canada, June 22.

American and British Superannuation Systems.

THE writer of the leading article on this subject in NATURE of June 30 may have misled your readers by the last paragraph but one in his article, because:—

(1) No money can go into the pockets of shareholders of mutual insurance companies; there are no shareholders.

(2) If an endowment assurance is taken under the Federated System the benefits are increased by the share of profits, which, in the case of a mutual company, means a full share of all profits made.

(3) The expenses of the selected insurance companies are probably little more than those necessitated by a separate "association" when we bear in mind that the premiums charged under the Federated System allow for the saving of "commission to agents" by those offices that usually employ agents.

(4) The Federated System obtains the advantage of the experience of insurance companies in investing money expeditiously on a large scale.

The objection quoted as having been made by Mr. Fisher on the second reading of the School Teachers (Superannuation) Bill, 1918, to the effect that public money would go in "dividends to the shareholders" is met by (1) and (2) above. The real difficulty of placing his pension arrangements in the hands of insurance companies is that they cannot assess the invalidity risk or the future salaries on which the pensions in the Bill depend. The invalidity risk, the future salary scale, and the longevity of pensioners have necessitated far heavier contributions to pension funds than had been expected when the funds were started, and the difficulty of keeping private pension funds in a solvent condition is so well known

to actuaries who have practical experience of them that the writer of the article may have thought it too obvious for reference. It is, however, an important aspect of the problem of providing pensions which ought not to be overlooked.

W. PALIN ELDERTON.

Mansion House Street, E.C.2, July 4.

[THE insurance companies selected by the council of the Federated Superannuation System are not all mutual companies, and, in consequence, there are shareholders and dividends to be taken into account. Apart from this, even among mutual companies such matters as directors' fees, palatial buildings, and highly paid officials are not unknown, not to speak of expenses, often heavy, of advertising. If Mr. Elderton wishes to maintain the position that insurance companies are purely philanthropic institutions, we fear he has taken on an impossible task.—ED.]

Cup and Ring Markings.

MAY I query Mr. Carus-Wilson's opinions in his letter in NATURE of June 23 (p. 523)? I have, alas! seen only one case (at Ilkley) of these markings, but have long been interested in the peculiar weathering of mortar which is common on the north side of old buildings near the sea. My view is that it is quite distinct from the cup and rings. The change in mortar is, I suspect, one of adsorptive precipitation, so well explained by Mr. S. C. Bradford in NATURE of March 23, 1916, and elsewhere.

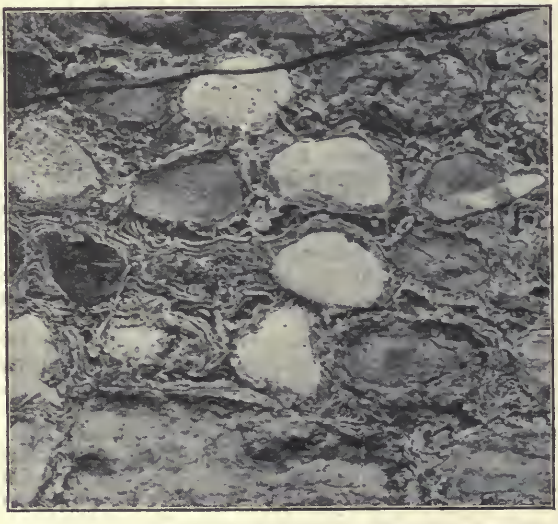

FIG. 1.

After saturation by rain, when drying takes place the lime forms into parallel lines with intermediate spaces, and those sand-grains which are thus robbed of their cement are speedily removed by the wind. The accompanying photograph (Fig. 1) is of an old stable wall built of local sandstones and limestones at the Military Arms Inn, The Nothe, Weymouth, and was taken in 1904. The scale is 1/10. I presume the cracks, etc., in old oil paintings are also quite unlike either of the above.

GEORGE ABBOTT.

June 26.

A New Acoustical Phenomenon.

WITH regard to Dr. Erskine-Murray's observation of the behaviour of aeroplane sounds (NATURE, June 16, p. 490), attention may be directed to the fact that any combination of confused noises will behave in the same manner, such, for example, as the noise of rustling leaves, escaping steam, a shower of rain on trees or tin roofs, or of a distant train in motion. If one stoops towards the road or approaches a reflecting wall while any of these noises are going on, the pitch of the sound rises, and when one is in the act of standing up, or of withdrawing from the wall, it descends. The grating of carriage-wheels on the road, or rather the noises reflected downwards from the body of the carriage, have a like effect when the observer is standing perfectly still. In this case, however, for some reason not clear to the writer, careful listening shows that the pitch falls as the vehicle nears the observer, and rises as it recedes from him. If the sound is a single continuous note, such as that of a whistle blown by a bicyclist riding past the observer, beats are heard as the whistle advances and also as it recedes, these being due to interference between the direct sound-waves and those reflected from the road. The occurrence of beats in such circumstances is perhaps not generally recognised.

F. M. WEST.

11 Downshire Square, Reading, July 12.

Magnetism and Atomic Structure.

ON the cubical atom theory developed by Lewis and Langmuir it appears that the molecules of CO_2 and N_2O have almost identical electron configurations. A. O. Rankine has shown from viscosity data that each electron system is equivalent to that of three adjoining neon atoms in line. The writer is not aware that attention has been directed to the fact that the specific susceptibilities of gaseous CO_2 and N_2O are $-0{\cdot}423\times10^{-6}$ and $-0{\cdot}429\times10^{-6}$ (Také Soné, Science Reports, Tôhoku, vol. viii., p. 162, 1919, and Proc. Phys. and Math. Soc. Japan, vol. ii., p. 84, 1920) and their molecular susceptibilities $-18{\cdot}6\times10^{-6}$ and $-18{\cdot}8\times10^{-6}$ respectively.

The electron systems of the two molecules are apparently identical, but the net positive charges on the atomic nuclei are $8-6-8$ for CO_2 and $7-8-7$ for N_2O. If, therefore, atomic nuclei possess rotations and are a source of magnetic moment, it must be assumed that the redistribution of the positive charges in the manner indicated involves no change of angular momentum.

A. E. OXLEY.

Shirley Institute, Didsbury, Manchester, July 14.

An Algebraical Identity.

WITH reference to the letters in NATURE of June 9 and July 7 by Dr. G. B. Mathews, Dr. H. C. Pocklington, and the Rev. J. Cullen on the polynomials $Y(x)$, $Z(x)$ satisfying the identity

$$Y(x)^2-(-)^{(p-1)/2}Z(x)^2=4(x^p-1)/(x-1),$$

may I point out that $Y(x)$, $Z(x)$ are tabulated as far as $p=101$ in Dr. Hermann Teege's inaugural dissertation, "Ueber die $\frac{1}{2}(p-1)$ gliedrigen Gaussischen Perioden" (Kiel, Peters, 1900)? Connected with these polynomials there is a further point which, so far as I am aware, has not yet been settled. When $x=1$ and $p\equiv1$ (mod. 4), $Y(x)=py$, $Z(x)=z$, and $py^2-z^2=4$.

I have verified from Dr. Teege's results that (y, z) is the primitive solution of $pu^2-t^2=4$, and consequently $\frac{1}{2}(z+y\sqrt{p})$ the primitive unit of the quadratic field $[\sqrt{p}]$ as far as $p=101$; but the question whether this unit is always primitive needs further investigation.

The University, Leeds.

The Air and its Ways.[1]

By SIR NAPIER SHAW, F.R.S.

THE physical problems of the weather map have not been solved, for the subject is inherently difficult. In the first place, the atmosphere is on such an immense scale that its behaviour is not to be brought under the principles of physics without much trouble, and, I may add, many mistakes. The most confident theories of the past are flatly contradicted by facts which have come to light since the investigation of the atmosphere was extended to the upper air by balloons, kites, kite-balloons, and more recently by airships and aeroplanes. We have now many facts about the atmosphere up to 20 kilometres at our disposal. They are, of course, not necessary for the formation of a correct theory, because no new principles are involved, but they are invaluable for the purpose of the verification or contradiction by which hypotheses get moulded into consistent theory.

The behaviour of air in bulk is so entirely different from that of the laboratory sample that the ways of the air are, indeed, as peculiar as those of "the heathen Chinee." The air as we know it in the laboratory is a very mobile fluid, yet in the atmosphere it manages to take on a sufficiency of the character of an elastic solid. It does not go in the way it is pushed; pushed north it goes east, and pushed east it goes south. The condition for getting it to go north is that it should be pushed west. If you blow a jet of air straight upward you may find that part of the effect is a vortex whirling around you. In front of its fire—the sun—the air will very likely get colder instead of warmer; losing heat by exposure to the clear sky on a cold night, it may get warmer. In spite of all that is taught in the laboratory about the levitating effect of warmth, cold air floats above us with warmer air beneath. If you tell the air that warm air rises, it winks an eye and interjects an "if" and a "when." If the Olympian gods felt cold and thought to make themselves warmer by stirring up their chilly air with the warmer air enjoyed by mortals down below them, they would be disappointed. Stirring would make them colder and us warmer. Shake air up violently, water falls out of it; and if the shaking went on long enough the air would become intolerably dry, very cold at the top and very warm at the bottom. Not only has the air the innate capacity for these conjuring tricks, but it never, or scarcely ever, fails to use them.

The General Problem of the Science of Meteorology.

Yet, underlying the work that is done in meteorology officially or unofficially, there is, and has been all the time, a definite purpose to bring our knowledge of the air into relation with the laws of physics as established in the laboratory, and, therefore, particularly with the laws of energy.

The Fundamental Facts.

There are two sides to the study of the air and its ways which can be pursued by different people who may never meet each other. One is the observation and collection of the facts about the weather from every part of the world; the other is the interpretation of facts by dynamical and physical reasoning. Nothing—at least nothing useful—can be done without real facts; but real facts do not, as a rule, explain themselves. The composition of air at different levels has been computed, and the results for one hundred kilometres are different according to Humphreys, Wegener, and Chapman. Below the level of 20 km. we are not troubled with changes of composition except those in the amount of water-vapour. The meteorological facts may be expressed by maps showing coast lines and orographic features, surface-temperature in January and July and its discontinuities at the coast lines, water-vapour at the surface in July, cloud, rainfall over the land, winds over the sea, and pressure over the globe in the same month.

Winds and temperatures in the upper air can be illustrated by models in cardboard. That for temperature shows the general run of the isothermal surfaces and the modifications caused by the introduction of local cyclones and anticyclones.

The Atmosphere a Great Steam Engine.

We are all agreed that the atmosphere is in reality a great engine, partly an air engine, but more effectively a steam engine, or at least a moist-air engine. Now the essential parts of a steam engine are a boiler to supply it with heat, a condenser at a lower temperature to absorb the surplus heat, and a fly-wheel to maintain the continuity and uniformity of its action. We describe the action of the engine as taking a supply of heat from the boiler, giving out heat to the condenser, and converting into work, useful or otherwise, the difference between the heat taken in and that given out.

Can we rightly use such language about the atmosphere and usefully contemplate the ways of the air from that point of view? I think we can, though the analysis of the phenomena from that point of view is difficult. The boiler is certainly there; I have shown it to you in the distribution of temperature with the great warmth of the equatorial regions. In the map of the distribution of water-vapour I have shown you where the steam is raised. The condenser is there also, partly in the shape of the vast cooling surfaces of the high lands of the arctic and antarctic regions, and of snow-covered mountains generally; but perhaps more effectively in the upper air, particularly in the stratosphere, which at a temperature of

[1] Abridged from the Rede Lecture at Cambridge on June 9.

190a. to 240a. (*i.e.* from 60 to 150 Fahrenheit degrees below freezing point) is certainly cold enough for the purpose, and, for certain reasons which I will not now expound, must be regarded as an effective means of getting rid of heat by radiating it into space.

The Fly-wheel of the Atmospheric Engine.

And what of the fly-wheel and the work done by the engine? Surely the winds, whether of the general circulation or of the local circulation of cyclonic depressions, are a fair representation of the fly-wheel. At the risk of laying myself open to the unpardonable sin of punning, I will point out that the fly-wheel is of enormous importance to flying, because the flyer can either attach himself to it and be carried along with it, or he may have to labour to make headway against it. The choice of these alternatives depends upon the airman's knowledge of its habits and behaviour—of its ways, in fact. The constituent parts of the fly-wheel at any time are the natural air-ways of the world. It was by hanging on to one part of the fly-wheel in the fifteenth century that Columbus discovered America, and by the aid of another portion, just two years ago (June 14, 1919), Sir John Alcock crossed the Atlantic in 16½ hours, and on July 13 of the same year Air Commodore Maitland landed R.34 at Pulham after a journey from New York in 3 days and 3 hours. Its total energy is tremendous, of the order of 100 billion horse-power-hours.

The Polar and Equatorial Circulations in the Upper Air as Parts of the Fly-wheel.

One of the immediate results of the thermal operations is to maintain the great fly-wheel or to start new sections of it in the form of local cyclonic circulations. Omitting these for the moment, I want to put before you some information about that part of the fly-wheel which is expressed by the general circulation. We can do so by distinguishing and ultimately isolating those portions of the atmosphere which represent permanent parts of the general circulation. Our best method of procedure is by way of pressure. We can compute the distribution of pressure for successive levels and verify the computation by the occasional observations of pressure at the various points of observation. We can thence calculate winds to correspond therewith in accordance with the general principle of the relation of pressure to wind, to which reference has already been made, and which finds partial expression in Buys Ballot's law.

A glass model expresses the results most clearly. It is made to show simultaneously on concentric hemispherical glass shades maps of pressure for 2000, 6000, and 10,000 metres. They disclose an enormous body of air extending at the higher levels from the pole or thereabout to latitude 40°, with a protuberance to the equator in the lower levels of the monsoon region. The air circulates about the polar axis in curves not exactly coincident with circles of latitude, but not very different therefrom. This mass of moving air constitutes a very considerable fly-wheel.

The maps also disclose a collection of anticyclonic circulations in the intertropical region lying between a stream of westward-moving air at the equator and a stream of eastward-moving air at about latitude 35°. Thus the margins of the anticyclones form a sort of chain-drive pulling the air from east to west on the equatorial side and pushing the polar circulation eastward. These vast local areas of high pressure are interesting in relation to the tracks of hurricanes, the normal path of which for this part of the year is marked thereon. The lines which separate the high-pressure areas are at the coast lines, and emphasise the meteorological importance of those lines; with one of them the hurricane track is evidently associated.

Local Cyclonic Circulations as Parts of the Fly-wheel.

Among the products of the working of the aerial engine we have included the energy of the circulation of local cyclonic depressions, whether they take the form of the hurricanes of tropical countries or of the milder depressions of our own latitudes. I anticipate no objection to the suggestion that these phenomena are part of the working of the general atmospheric engine; but there is so far no general agreement as to the precise way in which the engine operates to produce these results.

I have recently suggested that the development of a vortex of revolving fluid may be due to the "injector-effect," or, as I prefer to call it, the "eviction-effect," of rising air or falling rain or both combined, and I have put together an apparatus designed to test the effect of the various possible causes in producing a cyclonic vortex when the conditions of relative motion are favourable. I have come to the conclusion that the air is much more easily moved to take up cyclonic circulation than has hitherto been supposed, and, in fact, cyclonic circulation is the natural expression of a part of the kinetic energy of rising air or falling rain, requiring only favourable local conditions for its obvious manifestation. Perhaps I may add that on that ground a volcano in explosive eruption ought naturally to cause a local tornado. The energy of cyclonic motion can therefore be added to the other parts of the atmosphere's fly-wheel with some confidence that it is in accordance with natural fact.

An Indicator Diagram for the Atmospheric Engine.

If this view of the atmosphere is a reasonable one, then we ought to be able to refer the operations of the air to what Maxwell calls an *indicator diagram*, expressing by the area of a closed figure the work done by the air in the course of a cycle of operations represented by the outline of the figure. During the past forty years I have been

trying to get that diagram in continuation of the work that I used to do with a class at the Cavendish Laboratory, and now I believe I have succeeded, with the assistance of Mr. E. V. Newnham, of the Meteorological Office. The result is not exactly in the form which is familiar to readers of Maxwell, but in the form of an entropy-temperature diagram such as Sir Alfred Ewing uses in his work on the steam engine. With the diagram it ought to be possible to make a reasonable diagnosis of the ways by which air can ascend from the surface, and descend again to be prepared for a repetition of its cycle. We should then replace by reason the guesswork which has hitherto done duty for it. Further, according to the diagram, the best which you can expect from the steam-laden air of the equatorial region, working between the surface and the stratosphere under favourable conditions, is a "brake-horse-power efficiency of 25 per cent." Operations conducted elsewhere will have less efficiency than that. On the whole, it is not very high, but the energy available as indicated by the equivalent of the amount of rain which falls is so enormous that there is no reason to doubt the capacity of the air as a steam engine to develop and maintain the effects which are included in all our varied experience of the air and its ways.

Congress of the Universities of the Empire.

THE second Congress of the Universities of the Empire, which met in Oxford on July 5–8, was as successful as the Congress of 1912. Higher tribute could not be paid to the skill of those who were responsible for its organisation. Thirty-seven overseas universities were represented by ninety-four delegates and twenty-two "representatives," of whom the very large majority had come to England for the express purpose of attending the Congress. The total number of members, including Oxford residents, was about 600. In the printed list we find amongst the delegates the chancellor of New Zealand, the ex-vice-chancellor of Calcutta; the presidents of Alberta, British Columbia, Dalhousie, McGill, Queen's, Kingston, Saskatchewan, and Toronto; the vice-presidents of Montreal and St. Francis Xavier; and the principals of the University Colleges of Pretoria and Johannesburg and of several Indian colleges. When the present cost of ocean travel is taken into consideration, these figures bear eloquent testimony to the belief of the universities of the Empire in their essential unity and to their faith in their common mission.

In one respect the Congress of 1921 far surpassed that of 1912 in attractiveness, and probably in value also. With the greatest generosity the members of the University of Oxford offered the hospitality of their colleges and their homes to all members of the Congress. The meeting together in common rooms and in the houses of their hosts gave great pleasure to the men and women who had come from the most distant parts of the King's Dominions. The opportunities thus afforded of intercourse and of informal discussion are likely to produce results more important in their bearing upon the practice of teaching and administration than the speeches made in the South Hall of the Examination Schools.

Opportunities of consultation and of the comparison of experience are being further enlarged by the application of a scheme of visits which was tried on a smaller scale and in a somewhat tentative way in 1912. For a month all delegates from overseas are the guests of the home universities. Before Congress met they were given the choice of visiting Reading, Bristol and Cardiff, or Dublin and Belfast. Returning to London, as the guests of the University, they visited its schools and colleges on June 30 and July 1 and 2. On July 4 the Government entertained them, together with the delegates of the home universities, at a luncheon over which Mr. A. J. Balfour presided. On the following morning they travelled by special train to Oxford, where the congress was opened by the chancellor of the University, Lord Curzon. From Oxford the delegates from overseas proceeded to Cambridge and thence to either Edinburgh and St. Andrews, or Glasgow and Aberdeen. They will return in three parties *via* Durham, Newcastle, or Sheffield to Manchester or Liverpool, and will end their tour either in Birmingham or in Leeds.

As the proceedings of Congress have been reported in the daily Press, it will suffice here to mention only some points of special interest to men of science. As was fitting at a meeting in Oxford, the first session was devoted to the consideration of the balance of studies—the place of the humanities in the education of men of science, and of the physical and natural sciences in general education. Many wise things were said by the champions of a literary education. Prof. Desch and Prof. Whitehead spoke for those concerned with the education of students of science. Prof. Desch urged the necessity of including a large measure of humanistic instruction and study in the training of men of science, but proposed that it should take a novel form. In place of balancing the specialised courses in science by a certain number of equally specialised courses in the humanities, he would endeavour to bring the two into closer relationship by making the teaching of science historical, literary, and sociological. If scientifically trained men are to take their proper position in the community they must have "a vision of knowledge in its true proportions and perspective." "The most important safeguard against a limited vision is to be found in the historical spirit." Teachers should show to their students how their sciences grew, should

interest them in the lives of their founders and chief exponents, and, in favourable cases, in their original writings. In pure science the student should be shown how each discovery was related to the state of intellectual development at the time when it arose; in technology the opportunity should be taken of bringing discoveries and inventions into relation with the events of history and with the condition of society at different periods. The training of a scientific man could not, as a rule, include the study of dead languages; but modern scientific thought has its roots in ancient Greece.

Prof. Whitehead dealt with the preparation of schoolboys for scientific study at the university. "The main structure of successful education is formed out of the accurate accomplishment of a succession of detailed tasks." This must be ever kept in mind, since the enthusiasm of reformers so naturally dwells on "the rhetoric of education." The cynic is apt to proclaim that it does not make much difference what the detailed tasks may be; the one important thing is to get children into the habit of concentrating their thoughts and of doing what they are told. On the contrary, the wise selection of the detailed tasks is of prime importance. "Every subject in the preliminary training must be so conceived and shaped as yielding, during that period, general aptitude, general ideas, and knowledge of special facts, which, taken in conjunction, form a body of acquirement essential to educated people. Furthermore, it must be shown that the valuable part of that body of acquirement could not be more easily and quickly gained in some other way by some other combination of subjects." The hard element in a scientific curriculum consists in the attainment of exact knowledge based on first-hand observation. The soft element comprises two factors, of which the more important is browsing, with the very slightest external direction, and mainly dependent on the wayward impulses of a student's inward springs of interest. The second factor should consist of descriptive lectures, designed for the purpose of exciting general interest in the various sciences.

The afternoon session on July 6 was devoted to the consideration of "The Universities and Technological Education." Lord Crewe, the chairman, sounded the keynote of the discussion. No longer is it a question as to whether the universities should or should not provide training of the type defined as technological, but as to how far they should go in promoting studies which lead men and women on to employment in the fields of industry and commerce, or engage them in continued scientific research. "The universities exist because they satisfy the needs of the country—moral, intellectual, and practical—and the nature of the teaching they supply is conditioned by those needs. When, therefore, the conductors of an increasing number of industries assert that their methods depend for development and practical success upon scientific knowledge, and that it is only from the appropriate departments of different universities that such knowledge is forthcoming at its best, the universities have no choice." Lord Crewe directed attention to the outstanding success of the schools of agriculture of the two ancient universities.

Sir Arthur Currie gave an account of the highly organised courses for engineers at McGill. These courses extend over four sessions, and include economics, finance, and industrial law. During the three intervening summers students obtain practical experience in works. In virtue of their superior education, they are fitted, when they go into the active practice of their profession, to rise to positions in which they will lead and direct. Advanced courses in which students are taught how to conduct investigations are also arranged, the Canadian Government providing forty-five scholarships for graduates who show aptitude for research.

In the course of an able paper Prof. Smithells said: "I have always thought that our difficulties with technology have arisen chiefly from the belated and stinted cultivation of natural science in the ancient universities." "If natural science as it arose had been gathered to the older studies and had flowed in its natural courses, the mechanical arts and those who follow them would surely have been brought long since into a very different relation with the academic world." "It would be excusable, perhaps, to make this the occasion to preach the urgency of technology. But that is not my intention; I am far more anxious to raise my voice against its unbridled pursuit, to direct attention to the restraints under which it should be fostered, and to plead for what seems indispensable to its worth." Of the Department of Scientific and Industrial Research his experience led him to say: "I hope I exhibit some capability of seeing what is good in this new State Department. Of what appears not good I will only say this, that there seems most room for anxiety in the creation of isolated institutes for technological research, which may detach from universities a most valuable type of studies and of men that will themselves suffer from their isolation."

Mr. J. C. Maxwell Garnett contended that "the provision of the highest technological education by universities, instead of by separate institutions, tends also to benefit the industries by harmonising the ideals and purposes of leaders of the people in many different walks of life, by widening the interests of the future captains of industry, and by accustoming them to an atmosphere of scientific inquiry, so that in due course they will encourage research, well understanding that research is something more than experimental tests—more even than attempts to discover immediate industrial applications of established facts."

Prof. W. W. Watts, after sketching the purpose of technological education and the aims of the universities and other institutions which set themselves to prepare men for industrial life, said: "The scheme of education that will be evolved . . . will not greatly differ in its method from the older

forms of literary or scientific learning, nor will its value be less as an instrument for equipping the intellect and training the mind." On the subject of touch with industry, he continued: "Until the student knows some of the features of the industry in which he will be engaged, he finds it difficult to realise the significance of many parts of his training. . . . In my opinion, the advantages of early touch outweigh its disadvantages." "The type of men which it should be the aim of the universities to turn out . . . must be willing to study all the conditions of their problems before they are sufficiently satisfied with their solutions to carry them into effect. These conditions require, not a solution, but the solution which can be brought into operation with the least possible disturbance of the things that are, without needless change of raw material, machinery, or *personnel*, but with the advantage of diminished cost, enlarged production, and increased value or efficiency."

Presiding over the morning session on July 8, which was devoted to the consideration of "The Universities and Research," Lord Robert Cecil spoke of his friendship with Lord Rayleigh and of his astonishment at the freshness with which he retained until the last days of his life his interest in the advance of knowledge.

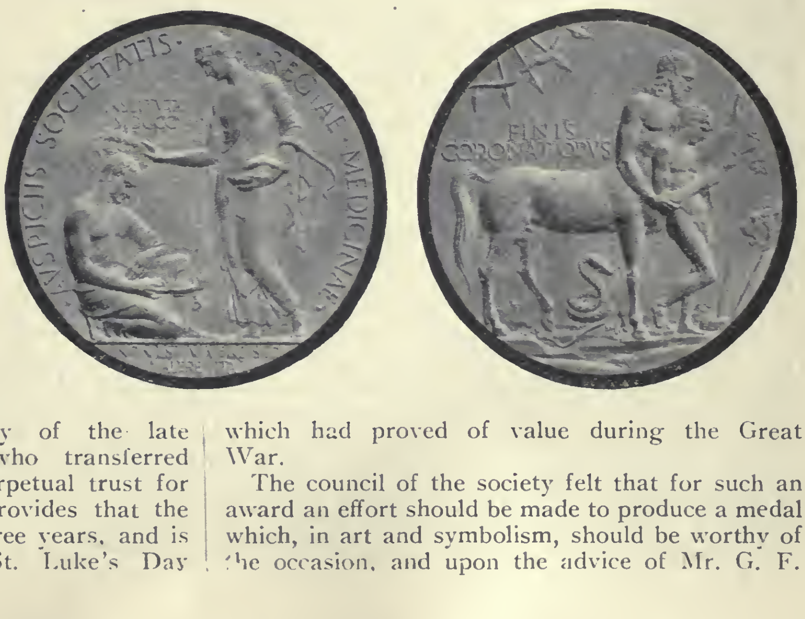
After a paper by Sir Frederic Kenyon on humanistic research, and one by Prof. Firth on historical research and university teaching, Prof. Joly spoke on scientific research. He recalled the fact that it was in Oxford that the Royal Society, the greatest of research societies, had its origin in the endeavours of such diverse spirits as Wilkins, Boyle, Wren, Seth Ward, and Wallis. "The argument for research in universities rests upon the broad basis of the value of the intellectual progress of mankind. I think I am correct in saying that most men who have adopted a life of research, or have made research the object of their special interest, have acquired their intellectual ideals in the days of their college life." If his teachers are without interest in research, the enthusiasm to create new knowledge is not implanted in the student. "Perhaps the most striking feature of American universities, as viewed by the British visitor, is the prevalence of research, and the lavish provision made for its prosecution. It extends into every branch of university work." "The American recognises to the full the value of the mental attitude induced by research, and this recognition is not confined to the university professor, from whom it may be expected, but extends, so far as I could gather, everywhere throughout the States."

The discussions of the Congress, which were carried on with great vigour, are likely to prove fruitful in the minds of those who heard them. The permanent, and perhaps more important, outcome will be the full Report of the Proceedings of the Congress, which will be published by Messrs. G. Bell and Sons in the autumn.

Gold Medal of the Royal Society of Medicine.

AWARD TO SIR ALMROTH WRIGHT.

At the recent annual meeting of the fellows of the Royal Society of Medicine the president, Sir John Bland-Sutton, announced that the recently founded gold medal of the society had been awarded to Sir Almroth Wright in recognition of the value of his important contributions to medical science, and particularly of those made during the war. Unfortunately, Sir Almroth Wright, who had been compelled to go abroad, was unable to be present, but had written very cordially thanking the council of the society and expressing his great appreciation of the honour bestowed upon him. In his absence, the medal was handed to his brother, Dr. Hagberg Wright.



The council of the society was enabled to institute the gold medal by the generosity of the late Dr. Robert Murray Leslie, who transferred to the society investments in perpetual trust for the purpose. The trust deed provides that the medal is to be awarded every three years, and is hereafter to be presented on St. Luke's Day (October 18) to a scientific worker, man or woman, who has made valuable contributions to the science and art of medicine. It was specially provided that the first award should, if possible, be made for original or other work in connection with military medicine and surgery which had proved of value during the Great War.

The council of the society felt that for such an award an effort should be made to produce a medal which, in art and symbolism, should be worthy of the occasion, and upon the advice of Mr. G. F.

Hill, keeper of the medals in the British Museum, the work was entrusted to Mr. Carter Preston, who has produced the beautiful design shown in the accompanying reproductions of photographs.

The obverse shows Hygieia, daughter of Æsculapius, placing a wreath upon a figure kneeling before her holding a lamp, signifying Research. The reverse shows the centaur Chiron instructing the young Æsculapius in the elements of medicine.

Obituary.

Henry Rondel Le Sueur.

Henry Rondel Le Sueur was born on January 1, 1872, the son of F. C. Le Sueur, of Trinity, Jersey. He attended a private school until 1887, and then for two years was in the laboratory of a Jersey analyst, Mr. F. W. Thoms. Thence in 1889 he proceeded to University College, London, taking the B.Sc. degree of the University of London (Honours in Chemistry) in 1893, and the D.Sc. degree in 1901.

Le Sueur's teaching experience was entirely connected with one institution—namely, the Medical School of St. Thomas's Hospital, where he was appointed demonstrator in 1894, and lecturer in 1904, a post which he was holding at the time of his death on July 9. There was but one break in his connection with the hospital—namely, that caused by the war. In July, 1915, he was commissioned major in the Royal Engineers, and ordered to Gallipoli to advise on chemical warfare problems, and the complaint which he contracted there was probably in no small degree responsible for his final illness. On his return to England he was one of those originally appointed to the Gas Warfare Experimental Station at Porton, Wilts., where he remained until the end of 1917, when he was ordered to the United States to assist in the preparation of the American Gas Warfare Experimental Station.

Le Sueur was one of the secretaries of the Chemical Society, and most of his original papers are to be found in the society's journal. He was a most capable experimenter, who found it necessary to satisfy himself on the minutest detail. This probably accounts for the fact that the number of his communications (twenty-four) was not large, but they are characterised by a thoroughness which can be rightly appreciated only by those who knew his methods of work. It was, however, as a teacher that Le Sueur shone as a particularly bright star. His capacity for imparting knowledge to others was most pronounced and quite exceptional, and among his students in the laboratory he was at his best.

Le Sueur's most marked characteristic as a man was his unfailing loyalty, whether to the science of his adoption, to his colleagues and students, or to his friends. Certainly the island of Jersey never possessed a more loyal or truer son. His efforts to mask a natural shyness and reserve of manner did not always meet with the success which would allow strangers to recognise the true qualities of the man himself, but those who knew him intimately realise that by his untimely death the science of chemistry has lost a devoted servant, and they have lost a true and loving friend.

A. C.

We notice with much regret the announcement in the *British Medical Journal* for July 16 of the death of Sir George Savage on July 5 at the age of seventy-eight years. Sir George was educated at Brighton and Guy's Hospital, where he won the treasurer's gold medal. He received the degree of M.D. (Lond.) in 1867, and in 1878 he was elected to a fellowship of the Royal College of Physicians. For seventeen years—from 1872 to 1889—he was connected with the Bethlem Royal Hospital, and it was during this period that his reputation as a psychiatrist was established. In 1886 he was president of the Medico-Psychological Association, and in succeeding years he presided over the Neurological Society and the section of psychiatry of the Royal Society of Medicine when this section was founded in 1912. In the same year he received his knighthood. For a number of years he was co-editor with Dr. D. Hack Tuke of the *Journal of Mental Science*. In 1907 he was elected Lumleian lecturer of the Royal College of Physicians, and two years later he became Harveian orator, taking as his subject experimental psychology and hypnotism. Sir George published one text-book, "Insanity and Allied Neuroses," which has become a standard work, in addition to numerous papers contributed to both English and American medical journals.

We record with regret the death of Sir Herbert Babington Rowell, which occurred suddenly on June 23. Sir Herbert, we learn from *Engineering* for July 1, was born in 1860, and finished his professional education at Glasgow University, where he studied naval architecture under Profs. Elgar and Jenkins. After experience with various shipbuilding firms, he became manager of the Hebburn shipyard of Messrs. R. and W. Hawthorn, Leslie, and Co., Ltd., and in 1916 became managing director of this firm. Sir Herbert was the first lecturer in naval architecture at Armstrong College, Newcastle. He was also a member of the council of the Institution of Naval Architects, and a member of the Institution of Civil Engineers. From 1912 to 1914 he was president of the Shipbuilding Employers' Federation, and from 1915 to 1917 president of the North-East Coast Institution of Engineers and Shipbuilders. In addition he was a member of Lloyd's Tech-

nical Committee, and filled many other public appointments. He received the honour of knighthood in 1918.

It is with great regret that we learn of the death of Prof. Gabriel Lippmann, Foreign Member of the Royal Society, on July 14 on board the liner *La France* while on his way from Canada, where he had formed part of the French Mission under Marshal Fayolle. Prof. Lippmann was born in 1845 and educated in Paris. His work there was concerned mainly with the relation between electrical and capillary phenomena, the outcome of which was his capillary electrometer and other instruments. His process of colour photography, announced in 1891, is widely known. In 1908 he was awarded the Nobel prize for physics, and in 1912 became president of the Paris Academy of Sciences.

We announce with much regret the death, on June 1, at the age of seventy-nine years, of Mr. Charles Pickering Bowditch, associate of the Peabody Museum of American Archæology and Ethnology, Cambridge, Mass. Mr. Bowditch was well known for his work on Mexican and Maya codices and inscriptions.

We regret to announce the death of Prof. J. A. Menzies, professor of physiology at Durham University School of Medicine, Newcastle-upon-Tyne.

Notes.

The Civil List pensions granted during the year ended March 31, 1921, amounted to 1200*l.*, and include the following:—Mrs. Frederick Enock, in recognition of her husband's services to natural science and entomology (September 7, 1920), 100*l.*; Mr. Edward Greenly, in recognition of his services in the geological survey of Anglesey (September 7, 1920), 80*l.*; Mrs. J. A. McClelland, in recognition of her husband's distinguished services as an investigator in physical science (September 7, 1920), 100*l.*; Mrs. and Miss Sharman, in recognition of Mr. George Sharman's valuable services in palæontological science (September 7, 1920), 80*l.*; Mr. John Nugent Fitch, in recognition of his long services to the cause of botany, horticulture, and natural history (September 15, 1920), 75*l.*; Mr. W. R. Hodgkinson, in recognition of his valuable scientific work in the public service (March 24, 1921), 100*l.*; and Mr. Herbert Tomlinson, in recognition of his services as a teacher, and of his valuable and distinguished contributions to physical science (March 24, 1921), 100*l.*

The popular fallacy that explosions can precipitate rainfall found expression in the question asked by Major Morrison-Bell in the House of Commons on July 13 as to whether the Government would be prepared to initiate experiments which might possibly have the result of precipitating a downpour of rain. The answer given was to the effect that from past experiments meteorologists were of opinion that explosions would not induce a fall of rain, and rightly so; for experiments were conducted on a vast scale, not, it is true, with that particular end in view, on the Western Front during the Great War. The collation of statistics of rainfall with the gunfire failed to show any certain connection. The only way in which the water-vapour in the atmosphere can be condensed into rainclouds is by cooling. Unless an explosion can produce a cold current, or cause to any appreciable extent such a disturbance in the atmosphere as will bring about the mixture of a stratum bearing a cold current with that carrying a warmer current, it cannot produce rain. The compression in the air produced by a bursting shell is propagated as a sound-wave. The amplitude of the motion, therefore, diminishes as the square of the distance from the origin, so that at the distance of a quarter of a mile it would probably be no greater than 1/10,000th of an inch. In 1917 M. Angot, Director of the French Meteorological Office, showed that in the extreme case of two equal masses of saturated air, one at 0° C. and the other at 20° C., it would be necessary, in order to produce rain of even so small an amount as 1 mm. (0·04 in.), for the two masses rapidly and thoroughly to mix throughout an atmospheric layer of 6850 metres (about 4 miles) in thickness. Nor are dust particles and ions, which form the nuclei of raindrops, sufficient of themselves to cause precipitation unless there be a concomitant reduction of temperature.

By a resolution of the Swedish Riksdag passed on May 18 last, it has been decided to establish an institute for the investigation of the problems of racial biology. To Sweden, therefore, falls the honour of being the first country to establish a State-supported institute of this kind. The history of the movement which led up to this decision is related in a pamphlet, written in English, entitled "The Swedish State Institute for Race Biological Investigation," which has just been published by Dr. Hjalmar Anderson. The success of the movement has been due largely to the indefatigable exertions of one man, Dr. Herman Lundborg, who was the first to direct attention in Sweden to the national importance of the study of eugenics in a lecture which he delivered to the Upsala Physicians' Society in 1904. After much strenuous advocacy on the part of Dr. Lundborg and other prominent men of science, the question was brought to the notice of the Riksdag, and a report was called for. As a result of the opinions then expressed, the Government took up the matter, and Dr. B. Bergvist, the Minister of Education, drew up a recommendation, which received the Royal sanction, in which it was proposed to found an institute with an annual appropriation of 80,000 crowns. In the meantime Dr. Lundborg, with a self-sacrifice worthy of all praise, had rejected an alternative proposal to establish a

chair for him in Upsala University, on the ground that a subsidy granted to an individual gave no assurance for the continued study of the subject in the future. The Riksdag, therefore, although unable to adopt the full recommendation as to the appropriation in view of the present financial situation, decided, as already stated, to establish a State institute, of which Dr. Lundborg will be the director.

In a letter referring to the leading article on "Internationalism" in Nature for July 7, p. 577, a correspondent writes to urge the necessity for a deeper and wider investigation of this complex question. In this connection attention may be directed to a little book recently published by Prof. H. J. Fleure, entitled "The Treaty Settlement of Europe" (Oxford University Press, 2*s.* 6*d.*), in which the author examines the provisions of the settlement from the ethnographic and geographical aspects. In his introductory chapter, after an admirable survey of the historical development of the conditions of life in Europe, Prof. Fleure points out that the treaties, using a framework which is largely linguistic, have attempted to apply to Europe the idea of the sovereign nation-State as it has arisen in the West; whereas, he holds, the coincidence of nation and State has been by no means close east of the Rhine. His chief and most weighty criticism of the treaties is that they tend to perpetuate conditions, and in particular the linear frontier, which have too often led to hostilities and disputes. He maintains that frontiers are really broad zones, and, further, that our politicians have failed to realise fully and to work out the implications of the fact that "in Europe we can only have unity in diversity." Prof. Fleure is perhaps inclined to attach too little weight to racial and nationalist feelings in the peoples of eastern Europe. The racial spirit of the Serb and the nationalism of the Greek are intense and deep-rooted, while in the more stolid Bulgar both sentiments are strong, if less demonstrative. Further east, in the Caucasus, which is beyond Prof. Fleure's province, in the case of the three republics which resulted from the Treaty of Brest-Litovsk, two, namely, Georgia and Erivan (Armenia), were the expression of a popular desire for a national existence which lent support to the political ambitions of their leaders.

In a letter to the *Times* of July 12 Mr. Robert Donald suggests that a corporation organised on commercial lines should be formed to conduct a general inter-Empire scheme for radio communication, the shareholders being the Governments of the States of the Empire, each represented in proportion to the capital it subscribes. The corporation should be directed by a small executive committee consisting of business men and engineers. The chain of radio stations could be built under contract, the corporation retaining ownership. The working of the system, however, should be leased to a company on attractive terms. In addition to directors appointed by the Governments, the British Radio Corporation should have on its board representatives of the Admiralty, War Office, Air Ministry, and Post Office. The advantages of this scheme are State ownership of an indispensable public service and private enterprise without monopolistic control. A company can also enter into international trade much more readily than can a union of States. The capital required for a few high-power stations with a working range of 6000 miles and low-power stations with a continuous working range of 2000 miles would not be great. The Compagnie Radio France has been constituted on somewhat similar lines. As the scheme is commercially feasible we hope that the Government will seriously consider it.

An interesting ceremony took place a few days ago at Lacock Abbey, near Bath, when, on behalf of Miss M. Talbot, a granddaughter of the late W. H. Fox Talbot and the present owner of Lacock Abbey, a large and historical collection of photographic apparatus was formally handed to Dr. G. H. Rodman, president of the Royal Photographic Society, for preservation in the society's museum at 35 Russell Square, W.C. It was Miss Talbot's desire that the collection should be placed in the care of the Royal Photographic Society, where it will be fittingly conserved with the important Hurter and Driffield collection and other photographic apparatus of national interest. The debt which modern photography owes to Fox Talbot, the brilliant scientific investigator, is not acknowledged so universally as it deserves, and although the credit for the discovery of photography may justly be attributed to the French pioneers, Niepce and Daguerre, Fox Talbot's discovery a short time afterwards revolutionised their process and made photography as it is practised to-day possible. The French process was completely different, and practically died out when wet plates were introduced. Fox Talbot was the first to produce positives from negatives, and as the inventor of the "Calotype" process he earned a title to undying fame. The collection of historical photographic apparatus which has now been entrusted to the care of the Royal Photographic Society includes a camera lucida, a sketching camera, and other scientific instruments which Fox Talbot used in his experiments, and will be specially shown during the approaching annual exhibition of the society, which will be opened to the public on September 19 next.

Some urgent appeals on behalf of Russian men of science have been received recently in Finland, and the University of Helsingfors has appointed a committee, which is endeavouring to give much-needed assistance. The frontier between Finland and Russia having been partially reopened, some Finns have been able to visit Petrograd and verify the accounts received. Already several wagon-loads of foodstuffs have been dispatched for distribution in Petrograd among men of science and their families, but it is feared that the present grave food shortage in Russian towns will become more acute in the immediate future. Supplies will therefore be required for some months, and the committee fears that the resources of Finland may not be equal to the task. In consequence, an appeal for help in this work is made to men of science throughout the world, and the committee has offered to act as an intermediary in conveying supplies to their destination. Gifts of food, clothing, and books are urgently needed, and the com-

mittee at Helsingfors guarantees that all packages entrusted to its care, which should be addressed to Prof. Mikkola, University of Helsingfors, will be delivered to the men for whom they are intended.

A DISPATCH from Col. Howard-Bury, leader of the Mount Everest Expedition, published in the *Times*, describes the course of the party from Kampa Dzong to Tingri Dzong, where they arrived on June 23. The illness of Mr. H. Raeburn, following on the death of Dr. A. M. Kellas, is a blow to the expedition. Mr. Raeburn was sent back to Lachen, in Sikkim, where his speedy recovery is anticipated. The march westward from Kampa Dzong does not appear to have been difficult except at times for transport troubles. The inhabitants were generally helpful. Col. Bury describes the ascent of the easy Tinki Pass leading to the wide valley of the Yaru, a tributary of the Arun. After fording the Yaru some difficulty was experienced in crossing an area of quicksands during a violent sandstorm, but no accident occurred. At Tingri Dzong the expedition was within 50 miles of Mount Everest and on the verge of the real work of exploration.

AT the annual autumn meeting of the Institute of Metals to be held in Birmingham on September 21–23, a number of papers dealing with the constitution and properties of metals and their alloys will be presented. The morning sessions will be devoted to the reading and discussion of papers, and the afternoon sessions will be spent in visits to works and factories of interest in the neighbourhood. The coming meeting will be the first visit paid by the institute to its old home, and the present membership of more than 1300 is significant of the great progress made by the institute since its foundation thirteen years ago, when its membership was 200. A ballot for the election of members desirous of attending the Birmingham meeting is being arranged, and full particulars can be obtained from the Secretary, 36 Victoria Street, London, S.W.1.

WE have received from the National Council of Public Morals (Rhondda House, 60 Gower Street, W.C.1) a pamphlet entitled "To Save the British Race," in which an outline of the activities of the council is given. The Birth-Rate Commission, a Special Committee on Venereal Diseases, an Adolescent Inquiry, and an Education Committee in relation to the kinematograph are some of the inquiries undertaken by the council, and valuable reports have already been published respecting some of these.

AN advisory body, the Scientific Research Committee, has recently been instituted by the Sudan Government for the collection and distribution of scientific information of local interest, which will be published in *Sudan Notes and Records*. In vol. iv., No. 1, of this publication Mr. R. E. Massey has a note on the maintenance of quality of cotton grown in the Sudan, showing that there has been no deterioration over a period of years; while Mr. H. H. King discusses means for the control of the Spanish sparrow, which has become a pest in Dongola Province.

M. V. GALIPPE, who is well known for his papers on micro-organisms, recently claimed (*Comptes rendus*, vol. clxxi., p. 754, October 18, 1920) that "microzymas et bacilles ovoïdes," endowed with movement, could be found in powdered fossils, even after treatment of the fragment used with a Bunsen flame and sterilised liquid reagents. No movement, however, was observed in ferruginous fossils. In co-operation with Mme. G. Souffland, M. Galippe now finds (*Comptes rendus*, vol. clxxii., p. 1252, May 17, 1921) that the same results may be obtained from meteorites and from a variety of igneous rocks, including those erupted by Mont Pelé. The authors are, of course, aware of the difficulties imported into their observations by the phenomenon of Brownian movement; but they state that their ovoid organisms move, while mineral particles of finer grain remain at rest. They believe that organic tissue and water are lost during fossilisation of the organisms, but that these are recovered during the experiments. The processes adopted will seem to most workers distinctly adverse to resurrection. The authors conclude that, if all living things were swept away from the surface of the earth, life would revive, thanks to the existence of the organisms entombed in every kind of rock. It is to be feared that few workers with the microscope will trouble to repeat these experiments, remembering Dr. Hann's observations on the structure of meteorites, and Mr. R. Kirkpatrick's more recent essay on "The Nummulosphere" (NATURE, vol. xci., p. 92, 1913); yet it is possible that the work of M. Galippe may lead to further study of Brownian movement among mineral particles.

THE results of investigations on the froghopper-blight of sugar-cane in Trinidad are given in a memoir of the Department of Agriculture of Trinidad and Tobago by Mr. C. B. Williams. The causative insect, *Tomaspis saccharina*, its life-history, and the nature of the damage done are described, and a section is devoted to the relation of the froghopper to its natural enemies. The sugar-cane is the second important agricultural crop in the island, and during 1917–18 it suffered a loss owing to blight of 300,000*l*. The causes accounting for the heavy outbreak of blight are due to a complicated interworking of many factors. The introduction of the mongoose to the island would not appear to be an important contributory cause. The preliminary conclusions arrived at open up a wide field of fundamental research on the relation between the outbreak of blight and rainfall, the geological contour of certain districts, soil conditions, temperature, rainfall, drainage, manurial treatment, tillage methods, and the relative resistance of varieties of sugar-canes. Direct control is also discussed. The author is to be congratulated on the way in which the results of his investigations are presented. It is highly desirable that sections of the report should be extended by further experimental research.

MEMOIR 122 of the Canadian Geological Survey has recently reached us, and it contains a comprehensive account of the Sheep River gas- and oil-field of Alberta, situated about 50 miles south of Calgary. Prior to 1915 a great deal of development work had

already been carried out by several companies, but owing to a variety of circumstances, largely influenced by the war, operations practically ceased in that year, though production has since been maintained intermittently by a few companies. The geology of the area is essentially Cretaceous, and the structures are typical of the eastern foothill ranges of the Rocky Mountains, consisting of sharp folds broken by powerful faulting consequent on long-continued earth stress. The main tectonic feature is that of the Turner Valley anticline, from which the bulk of the oil and gas has been obtained; this involves the Kootenay-Dakota, Benton, and Belly River series (in ascending order); petroliferous horizons are principally confined to the older rocks, four distinct oil-sands being recognised. Water-bearing beds were not penetrated by any of the wells put down, although two of these reached a depth of 3900 ft. The yield of gas is as much as 5,000,000 cub. ft. per day in some cases, while the best oil well (South Alberta Oil Co., No. 1) produces 30 barrels per day. The gas has an average composition of 70 per cent. of methane, the rest being ethane and nitrogen; the oil has a specific gravity of 0·736 (example from the second oil-sand), and is described as a high-grade oil; the yield of petrol, however, varies considerably. As a technical publication this memoir maintains the high standard of excellence characteristic of Canadian official literature.

METEOROLOGICAL results for 1920 at the Falmouth Observatory, a station which is financially assisted by the Meteorological Office, show that bright sunshine was registered for 1508 hours, or 245 hours fewer than the average for the past forty years. A deficiency of sunshine occurred in each month except December. Bright sunshine was registered on 308 days, a figure which is four days above the mean. The mean temperature for the year was 51·4° F., or 0·7° above the average. The absolute maximum for the year was 70·1° F. in August, which is the lowest annual maximum since observations were started fifty years ago. Rainfall was 2·08 in. above the average for the last fifty years. The relative distribution of the wind was in good agreement with the normal. A fifty years' average, 1871–1920, is given for atmospheric pressure, air temperature, rainfall, humidity, and direction of wind for each month and for the year; these add much to the valuable work which is being done at the station.

IN the July issue of the *Philosophical Magazine* Mr. E. C. Kemble, of Harvard University, reviews the evidence now available for testing the various suggestions which have been made as to the constitution of the helium atom. Bohr's hypothesis that it contains two electrons revolving in a common circular orbit is not in keeping with the known value of the ionisation potential. The models of Landé and of Franck and Reiche involve an outer and an inner electron each with its own orbit. Such an outer electron would, on the theories of Langmuir and of Sir Joseph Thomson, determine the chemical behaviour of the atom, and it would be difficult to reconcile the chemical properties of helium with those of the alkali metals. These models also give wrong values for the ionisation potential, and do not harmonise with the spectroscopic observations of Fricke and Lyman. In all the models the average angular momentum of an electron is taken to be an integral multiple of the unit, and, according to Bohr's principle, an electron on changing its orbit emits one or more units of radiation. Mr. Kemble shows that the principle cannot be applied in all cases without leading to inconsistencies, and comes to the conclusion that it must be abandoned.

IN *Science* for May 20 Dr. S. J. Barnett, of the Terrestrial Magnetism Department of the Carnegie Institution, Washington, reviews recent progress in the theory of magnetism and its simplest applications. He shows how the Weber-Langevin theory, according to which the magnetic element contains a permanent whirl of electricity with a definite magnetic moment, is incapable of explaining the known facts of dia-, para-, and ferro-magnetism, and that the magnetic element, or magneton, must be taken as having an angular velocity of its own about some axis which may or may not be an axis of figure. In these circumstances the magneton will behave as a gyrostat, and a rotation impressed on the body of which the magneton forms part will tend to make the magneton set its axis more in the direction of that of rotation of the body, and thus impart to it a magnetisation along the axis of rotation. The gyrostatic magneton in the hands of Ganz and of Honda and Okuba has yielded results which follow very closely the experimental facts, the theory of Ganz covering a wide range of cases, and in particular reproducing accurately the behaviour of dense paramagnetic bodies at low temperatures.

SIR WILLIAM ABNEY'S career as a scientific photographer forms the subject of a memorial lecture delivered by Mr. Chapman Jones before the Royal Photographic Society, and published in the *Photographic Journal* for July. From his youth Sir William Abney had more than a liking for scientific subjects, but photography was his first choice. At that time the spectroscope was beginning to take its proper place as an instrument of investigation, and he was one of the first to enter this new field and to apply the spectroscope to the elucidation of photographic problems. He took advantage of the fact that the exposure effect in a chromated gelatine film, if merely started by light, will continue to grow, and showed how the bugbear of the carbon printers could be turned to useful account. In 1871, if not earlier, Abney devoted his attention to the preparation of photographic emulsions and sensitive films, and later on obtained results from which the modern P.O.P. originated. During about twenty-four years he investigated the nature of the developable image and the course of development. By 1880 he had worked out various methods for printing by development. He made a series of experiments on developing agents, and introduced the use of hydroquinone and the ferrous-citro-oxalate developer, which need no restrainer. One of Abney's most important discoveries he called "the failure of a photographic law." He proved that the time of exposure did not vary exactly inversely to the

intensity of light. It was not until 1893, after the subject had been considered for twenty-two years, that he gave details of his investigation of it. He made many successful experiments on photography in natural colours, but his greatest self-contained achievement was his photography of the infra-red. The normal spectrum as photographed on his plates was more than five times the length of the visible spectrum, for they were sensitive to the ultra-violet right away through the visible spectrum to a wave-length of 2200$\mu\mu$. Abney was accustomed to quantitative work from the first, and perhaps the most important service he rendered was the introduction of methods of measurement into scientific photography.

THE *Comptes rendus* of the Paris Academy of Sciences for June 20 contains a note by M. Baille-Barrelle on the production of coke from Sarre coal. By the usual method of coking, this coal is well known to give a poor coke, but M. Baille-Barrelle shows that, by a special mode of heating, Sarre coal can be made to yield a coke comparable with the finest cokes from Ruhr coal. The experiments were made on a semi-industrial scale (charge of 500 kg.), and preliminary work on the extension to a full commercial scale has been commenced. The coal is first maintained at a temperature of 320° C. for some time; then the temperature is slowly raised uniformly to a final temperature of 750° C., or about 200° C. below the usual coking temperature. Figures for the resistance to crushing and shaking are given. It is also claimed that the by-products obtained are superior to those given by the ordinary coke oven, and an investigation into their nature is in progress. The yield of ammonia was unexpectedly high, about double that obtained when the coal is coked in the ordinary way; owing to the lower temperature a reduced quantity of ammonia was anticipated. It is probable that the actual quantity of ammonia produced was less, and that the increased yield was due to the lessened amount decomposed into nitrogen and hydrogen. If the process is successful on the large scale, the Lorraine iron industry will be freed from the necessity of using Ruhr coke.

THE National Physical Laboratory has issued a pamphlet dealing with "Tests on Volumetric Glassware Used in Dairy Chemistry," single copies of which may be obtained free of charge on application to the Director, Metrology (Glass Testing) Department, National Physical Laboratory, Teddington. The pamphlet contains specifications as to size and construction of butyrometers, test-bottles, and pipettes which can be accepted for test by the Laboratory.

Our Astronomical Column.

AURORÆ AT A HEIGHT OF 500 KM.—The careful auroral observations made in Norway and Sweden have established the remarkable fact that some of the streamers extend to the height of 500 km. above the earth's surface. This presumably implies that there is a certain amount of atmosphere at that height, which is a conclusion of cosmical importance.

Geofysiske Publikationer, vol. ii., No. 2, contains an investigation by Dr. Carl Størmer of the height of streamers during the brilliant aurora of March 22–23, 1920. There were seven photographic stations at work in Norway on this occasion, and telephonic communication enabled simultaneous exposures to be made, the cameras being directed to the same stars. The investigation is based on simultaneous photographs taken at Christiania and Kongsberg, which are 65·7 km. apart. The streamers photographed had well-defined edges, and crossed the constellation Cassiopeia, the brighter stars being visible on the plates. The heights of seven points in the streamers are determined as 597, 550, 607, 562, 528, 485, and 519 km. respectively. Two pairs of plates are reproduced, on which the streamers and the stars are clearly visible. The author notes that it is only the extremities of the long rays that attain these great heights. The bases may be as low as 85 to 90 km.

THE MINOR PLANET EROS.—This planet will make one of its near approaches to the earth early in 1931, when there will doubtless be another solar parallax campaign. A parallax still more accurate, however, than that obtained by direct measures will probably be determined by the very large perturbations produced by the earth on the planet's motion. For this purpose it is desirable to obtain accurate observations at every opposition. The planet will next be in opposition in mid-September in N. decl. 14°, magnitude about 10½. Mr. F. E. Seagrave has computed an ephemeris for Greenwich midnight, a portion of which is given below. Corrections, due to G. Stracke, of −22s. and −2′ 7″ have been applied to the right ascension and declination:—

JUPITER'S FOUR GREAT SATELLITES.—The Annals of Leyden Observatory (vol. xii., parts 1 and 2) consist of researches on these satellites by Prof. W. de Sitter and Dr. A. J. Leckie respectively. These parts were published in 1918 and 1919; they are therefore quite independent of Prof. Sampson's theory, which only appeared in print in 1921. One point of Prof. de Sitter's method is the use of a new intermediary orbit; instead of using the Keplerian ellipse, he substitutes for the eccentricity the great periodic inequalities. This is analogous to the use by Drs. Hill and Brown of the variation oval as intermediary orbit in the lunar theory instead of the Keplerian ellipse.

Prof. de Sitter finds for the masses of the satellites in terms of that of Jupiter 3796, 2541, 8201, and 4523 (units of the 8th decimal). In terms of the moon's mass these are 0·985, 0·659, 2·128, and 1·173. Using the diameters of the satellites found by the interferometer (mean of Hamy's and Michelson's results), viz. 1·00″, 0·905″, 1·325″, and 1·31″ at distance 5 units, the densities become 0·853, 0·788, 0·811, and 0·462 in terms of that of the moon.

Prof. de Sitter's final values of the mean daily motions of I., II., and III. referred to First Point of Aries are 203·48899280°, 101·37476180°, and 50·31764630°. These have been adjusted to fit the relation $n_1-3n_2+2n_3=0$.

Quality of Protein in Nutrition.[1]

By Dr. R. H. A. Plimmer.

THE normal diet of man and animals contains certain nutritional elements every one of which is essential for the maintenance of life and health. These elements are:

(1) Proteins, complex nitrogenous substances found in meat, milk, eggs, cereals, and plant tissues.

(2) Carbohydrates, such as starch in cereals, sugars in fruits, milk, etc.

(3) Fats, such as butter, lard, suet, and vegetable oils.

(4) Salts, or the mineral constituents in meat, milk, cereals, vegetables, etc.

(5) Vitamin A, contained in butter, cod-liver oil, eggs, green vegetables, etc.

(6) Vitamin B, contained in yeast, germ of cereals, meat, eggs, etc.

(7) Vitamin C, contained in some fruits and some vegetables.

(8) Water.

If we examine these food elements in fuller detail we find that in whatever form the carbohydrate is taken in the food it is converted during digestion in the body into a simple sugar, such as grape-sugar; so that for nutritional purposes all carbohydrates can be considered the same. They are burnt up like coal to supply the body with heat and energy.

Fat of almost every source consists mainly of three triglycerides, palmitin, olein, and stearin. The consistency of fats depends simply on the relative proportions of these substances. Certain fats are the vehicles of the A vitamin, but, leaving the vitamin out of consideration, fats are of equal value in nutrition, and, like carbohydrates, they supply fuel for heat and energy. Fats can be built up in the body from the carbohydrate in the food. Some very recent feeding experiments by Osborne and Mendel indicate that fat, as such, can be omitted from the diet if the vitamin A is supplied in a specially prepared form. The special value of fat in nutrition thus depends on the A vitamin associated with it, and not on its chemical constitution.

The mineral salts in an ordinary mixed diet do not need to be supplemented, but generally some sodium chloride is added. Animals on cereal diets must be supplied with this common salt.

Whatever is the source of the three vitamins, so far as we know the A vitamin is the same whether it be in butter or cod-liver oil, B vitamin is the same in yeast and cereal germ, and C vitamin the same in orange-juice or cabbage.

Thus, since each of these elements of the diet is reduced to a simple common basis during digestion, we cannot speak of quality of carbohydrate, fat, or vitamins.

The protein constituent differs from all the others by its endless variety. This is obvious to the naked eye. For instance, the protein in white of egg is in solution, and sets to a hard mass on boiling. Meat protein is already in a solid form. Milk contains two kinds of protein, the casein which is used to make cheese and an albumin like egg-albumin in the whey. The presence of protein in cereals is scarcely recognised, as it is obscured by the large amount of starch, yet about one-tenth of flour is protein; in fact, two very special proteins are present, the one soluble in alcohol, the other insoluble but soluble in dilute alkali.

Our usual classification of proteins already indicates their differences, but the variety is really far greater. We need only refer to their chemical analysis. Fischer, Kossel, and their pupils have shown that proteins on hydrolysis break down into some eighteen or twenty amino-acids. These numerous units can be arranged for convenience into eight groups:

(1) *Simple Mono-amino-Acids:* Glycine, alanine, valine, leucine, and *iso*leucine

(2) *Mono-amino-Dibasic Acids:* Aspartic acid and glutamic acid.

(3) *Hydroxyamino-Acids:* Serine and hydroxyglutamic acid.

(4) *Heterocyclic Acids:* Proline and hydroxyproline.

(5) *Mono-amino-Acids with Aromatic Nucleus:* Phenylalanine and tyrosine.

(6) *Mono-amino-Acid with Indole Nucleus:* Tryptophan.

(7) *Hexone Bases or Diamino-Acids:* Lysine, arginine, and histidine.

(8) *Thio-amino-Acid:* Cystine.

The chemical analysis of the proteins shows that the various proteins yield different amounts of the amino-acids. Some of the data are shown in Table I. The peculiarities of each protein are indicated by the figures in heavy type.

Total ...	67·5	66·5	57·0	65·4	83·0	59·72	85·4	45·7	81·9	83·1

In general, the albumin group of proteins contains all the amino-acids, except glycine, in various proportions. The globulin group is similar, but contains glycine, and has, in addition, a higher amount of glutamic acid, especially those globulins of vegetable origin. The phospho-proteins resemble the albumins, with no striking preponderance of any single amino-acid. The gliadin group of cereal proteins is peculiar in its high content of glutamic acid and proline. The members of the sclero-protein group (horn, hair, and gelatin) are heterogeneous, and here we may note that silk-fibroin is composed mainly of three mono-amino-acids, and is the very antithesis of sturin (the protein of fish sperm), which is made up of the three hexone bases with no, or very little,

[1] From a discourse delivered at the Royal Institution on Friday, April 8.

mono-amino-acids. Gelatin lacks cystine, tyrosine, and tryptophan. Hair is richest in cystine. These are simply some of the most obvious differences. Proteins thus differ markedly in quality.

Our analytical data are far from complete; in no case do the totals of the amino-acids add up to 100. The incompleteness is chiefly due to the great difficulty of separating and estimating the individual amino-acids. There may be still some unknown amino-acids in small quantities; *e.g.* hydroxyglutamic acid has been discovered recently by Dakin by a new extraction method. This method may yet lead to new results; once again it has proved that every new process in connection with the chemistry of the proteins has given a valuable result.

Rather too great stress has been laid upon the analytical figures. The methods scarcely give exactness as far as the decimal figure, and it would have been better if the data had been returned to the nearest whole number. Many workers still give their data to two places of decimals, so that an entirely wrong impression is given of the accuracy of the method. Fischer pointed out that his method was not quantitative, but others have neglected this important statement.

The figures for the hexone bases are more accurate, but it is still not sufficient to express results to two decimal places. Kossel considers that the hexone bases form a special nucleus on account of their presence in all proteins. We might value a protein by its content of hexone bases, but it is not sufficient, because their total only tells us about a third or less of the whole molecule.

Tryptophan, discovered by Hopkins and Cole, is perhaps the most important unit in the protein molecule. It is not estimated except by direct isolation—a method which is laborious and requires considerable skill. Its amount is not known except in casein and a few other proteins. By its distinctive colour reaction with glyoxylic and sulphuric acids it can readily be proved to be a constituent of most proteins.

The amount of cystine in proteins is known only in a few cases, but its amount can be gauged by the sulphur content of the protein. It is the one unit known which contains sulphur, but there are indications that there is another sulphur-containing unit.

The differences in proteins are not confined to such quantitative data; they are still more involved. Fischer's synthetical work with the amino-acids has proved that the amino-acids are combined together in a polypeptide form, *i.e.* the amino-group of one amino-acid is combined with the carboxyl group of another, the amino-group of this acid being united with the carboxyl group of still another. We therefore consider a protein molecule to be a chain of amino-acids, thus:

$$H_2N{\cdot}CH_2{\cdot}CO{-}NH{\cdot}CH(CH_3){\cdot}CO{-}$$
$$NH{\cdot}CH(C_4H_7){\cdot}CO{-}NH{\cdot}CH(C_3H_5){\cdot}CO{-}$$

This method of combination allows theoretically of endless variation. If we take three amino-acids we can arrange them in six different ways: Glycylalanyltyrosine, glycyltyrosylalanine, alanylglycyltyrosine, alanyltyrosylglycine, tyrosylglycylalanine, and tyrosylalanylglycine. With eighteen or twenty amino-acids the number of arrangements is almost infinite.

Differences in arrangement may be the cause of differences in proteins. Two proteins may perhaps have exactly similar amounts of amino-acids and yet be different; a difference could be expressed by the interchange of one amino-acid. We may imagine the proteins of the blood or milk of different species to differ thus: one may have the arrangement *a, b, c, d, e, f*, the other *d, a, b, f, e, c*.

Another important difference may exist in the so-called tautomerism of the amino-acids and polypeptides. With the same arrangement of the amino-acids we may have several formulæ representing the polypeptide structure. Certain of the properties of the polypeptides can be explained on this basis.

Fischer and Kossel have revolutionised our conception of protein nutrition. We no longer think, like Liebig and others, that the protein of the food becomes directly the protein of the body, for it has been demonstrated by the physiologists that the protein of the food undergoes hydrolysis during digestion to amino-acids, that the amino-acids circulate in the blood, and that the tissues receive amino-acids from which they build up their protein. Proteins must be regarded as a mixture of amino-acids.

We can look upon a protein as we look upon the contents of a box of assorted biscuits, arranged in rows and layers of various kinds. Each biscuit should be connected to its neighbour so that we have a continuous chain. The general appearance of the contents of two boxes is different; in one case we may find sugary biscuits on the top, in another plain ones. In the process of digestion the protein is acted upon by acid in the stomach with the formation of metaprotein. No great chemical change occurs, but we can imagine that the change consists in a tautomeric re-arrangement in preparation for the action of pepsin. Pepsin hydrolyses the protein at certain junctions, forming proteoses and peptones. Their formation can be compared with the separation of the layers of the biscuits. Pancreatic and the further digestion which follow in the intestine separate the individual amino-acids or biscuits entirely. The separate parts circulate to the tissues; the tissues select the ones they require, and form another arrangement of the units or simply replace those which have been used in their metabolism. Digestion and metabolism are a sort of re-shuffling of the units. In the absence of any particular unit the tissue can no longer rebuild its substance, and consequently suffers. The old example of the inadequacy of gelatin is now explained; the tissues require tryptophan, tyrosine, and cystine, and gelatin cannot provide them.

In nutrition there are essentially two problems to study: the formation of new tissue, as in the growth of young animals, and the maintenance of tissue, which undergoes so-called wear-and-tear, in adult animals. In the latter case we have ultimately to ascertain if every unit of the molecule breaks down or certain selected units only. If these are in the middle of a chain it would follow that the whole molecule would undergo metabolism, and not units at the ends alone. The problem resolves itself into ascertaining the function of each amino-acid.

Since the practical difficulties of feeding animals with a mixture of pure amino-acids are far too great, advantage may be taken of feeding incomplete proteins and adding to them the missing unit or units.

Wilcock and Hopkins made the first experiment of this kind in 1906. They selected zein as protein and fed it to mice, in one set alone and in another set with the addition of 2 per cent. of its amount of tryptophan. Young mice on zein alone immediately began to lose weight and generally died in sixteen days; decline in weight also occurred in the other set, but with the added tryptophan death did not occur until the thirtieth day. Adult mice lived twenty-seven days without tryptophan, and forty-nine days with tryptophan. Tryptophan had thus an appreciable effect on the survival period of the animals. Zein is incomplete in respect of other units, and death was probably on this account.

The experiment was repeated in 1916 by Ackroyd and Hopkins under different, but better, conditions.

The animals were first given a mixture of amino-acids from casein (*i.e.* without tryptophan, which is destroyed in hydrolysis by acid) to which tryptophan was added; on the twelfth day the tryptophan was omitted, and included once more on the thirty-fifth day. There was growth during the first period, decline in weight during the second period, followed by growth on inclusion once more of the tryptophan. This is shown by the continuous lines in Fig. 1. The upper dotted line shows continuous growth on com-

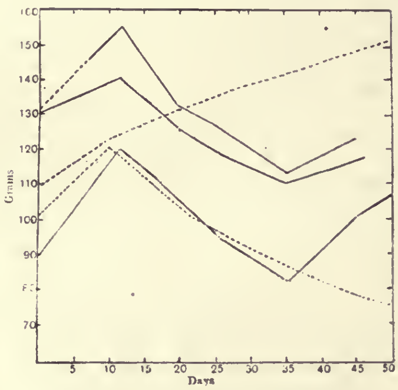

FIG. 1.—After Ackroyd and Hopkins.

plete mixture. The lower dotted line shows loss of weight in absence of tryptophan.

Similar experiments have been made by Osborne and Mendel in America. They used the gliadin of wheat as protein. This protein is a complete one, but it contains very little of certain amino-acids, especially lysine. Adult rats were maintained for quite long periods, so long as 500 days, but young rats capable of growth, though maintained for long periods, failed to grow.

We may here notice that though the growth of the animal may be suppressed and it reaches maturity in age, the capacity to grow is not lost. Osborne and Mendel illustrated this by a photograph of a rat which had failed to grow for 273 days, but resumed growth on being given a suitable diet.

The small amount of lysine in gliadin led the authors to regard this unit as essential for growth. In a later experiment they added lysine at intervals; growth took place with the lysine, but not without it. Fig. 2 shows the upward curve of growth with lysine, but no growth without it, in four sets of rats.

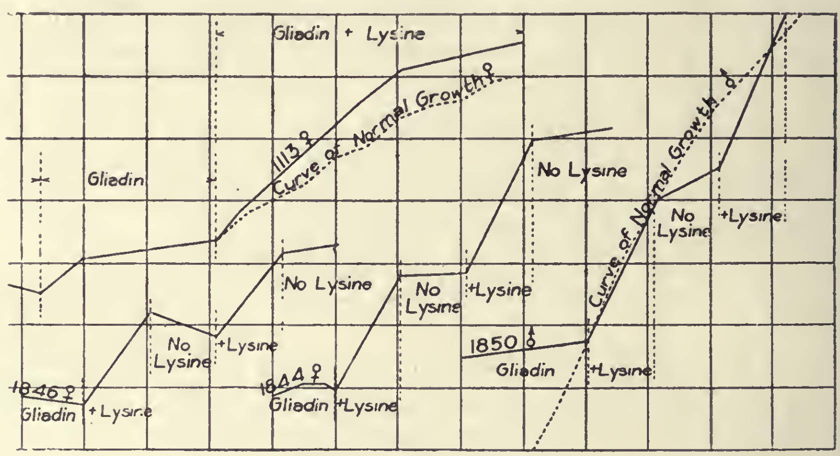

FIG. 2.—After Osborne and Mendel.

The effect of lysine on growth was again demonstrated by Buckner, Nollau, and Kastle in the case of chickens living under the natural conditions of a poultry farm. The birds were fed upon grain mixtures of high and low lysine content; growth was more rapid on the mixture of high lysine content.

The element sulphur is present in proteins in the form of cystine, though it is possible that another sulphur-containing unit is present. Little or no cystine in a protein has also an effect upon the growth of rats. This has been most clearly demonstrated in the case of the protein, phaseolin, of the navy bean. There was slow growth with this protein alone, but normal growth if the protein were supplemented with 2 per cent. of its amount of cystine.

Casein is deficient in cystine. Less casein is required in a diet for producing normal growth; if extra cystine be included 15 per cent. of casein was required by itself, but only 9 per cent. if cystine were added.

The amino-acids containing aromatic nuclei are probably essential units of the protein, but it is difficult to carry out a decisive experiment, since all proteins contain phenylalanine, though they may lack tyrosine. There is plenty of evidence that phenylalanine can be transformed in the body by oxidation; both tyrosine and phenylalanine yield homogentisic acid in cases of alkaptonuria. Totani has shown that the almost complete removal of tyrosine from the mixture of units yielded by casein made no difference to the growth of rats. There was evidently enough phenylalanine for all purposes.

The two hexone bases, arginine and histidine, as shown by Ackroyd and Hopkins, are interrelated in nutrition. Absence of both causes loss of weight; absence of either alone lessens the rate of growth. These two workers further showed that these amino-acids are connected with the production of the purine ring in the animal body, *i.e.* with the production of uric acid.

The function of the whole group of mono-amino-acids has yet to be determined. Are they all necessary? Of glycine we can say that it is not essential, for it is the only amino-acid which the animal can synthesise.

These results remind us of the well-known experiments on the need by plants of all the inorganic elements. Sir Daniel Hall in his "Fertilisers and Manures" gave a striking picture of barley-grains grown on a full food and on foods lacking one constituent. We may thus correlate the amino-acid content of proteins for the growth of animals with the set of inorganic elements needed for the growth of plants.

The relative value of various proteins in nutrition has been studied by Osborne and Mendel. In their experience lactalbumin is superior to casein, and casein to edestin. They found that 50 per cent. more casein and 90 per cent. more edestin were required to produce the same gain in weight; in other terms, a food containing 8 per cent. of lactalbumin was equal to one with 12 per cent. of casein and 15 per

cent. of edestin. Fig. 3 shows that the same amount of growth resulted in the same time with these quantities of proteins.

Suitable mixtures of proteins have also been tested, and attempts are being made to find out the most convenient addenda for making the proteins of cereals more adequate for the growth of animals, *i.e.* adding what we may call "good" protein to "bad" protein to make the latter efficient as food. Leaf and seed proteins are good as a mixture. Fig. 4 shows that if zein $\frac{1}{4}$ be supplemented with lactalbumin $\frac{3}{4}$, normal growth results.

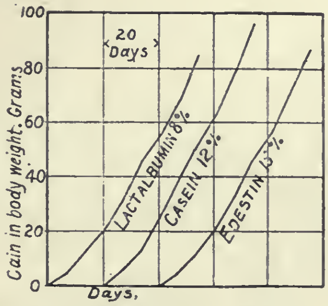

FIG. 3.—After Osborne and Mendel.

Economically, it may be better to use an expensive protein as food for animals and produce rapid growth than to feed for longer periods on poor proteins and get slower growth. A simple calculation brings out the problem to be solved. We may wish to build up the casein of milk with 16 per cent. of glutamic acid, and we are provided with wheat gliadin with more than 40 per cent. of this unit. There is waste of glutamic acid. Gliadin further contains 0·2 per cent. of lysine, whilst casein contains 6 per cent. To produce this

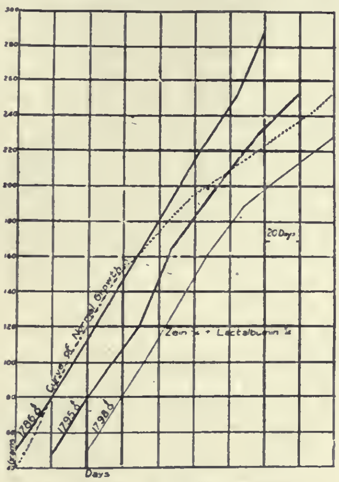

FIG. 4.—After Osborne and Mendel.

amount we require thirty times as much gliadin, and, consequently, the waste of glutamic acid is further increased.

Cannibalism is the most economical method of protein nutrition, as the amino-acids of the food are in the exact proportion required by the tissues. The nearest parallel to this is the nursing of the young animal by its mother; the child actually gets the proteins of the mammary glands.

Recent work shows that quality of protein is most probably the primary cause of the disease pellagra, although there are some indications that general insufficiency of protein together with improper salt supply are contributory factors.

Pellagra is a peculiar disease characterised by severe disturbance of the whole digestive tract, by skin lesions, usually bilaterally symmetrical, and often mistaken at first for sunburn or chapping of the hands, face, neck, and other exposed areas. The nervous system is also affected. There is no definite record of pellagra in Europe before maize was introduced into Spain by Columbus. From Spain the disease spread to France, Lombardy, and eastwards, wherever maize was extensively used for food in the poorer agricultural districts. The relation of maize to the disease puzzled the medical profession for nearly two hundred years, for the disease also occurred where maize was not used, while in some districts maize was used but there was no pellagra. Roussel in 1866 showed that it could be cured by good food, and Lorentz (1914) and Willets (1915) successfully treated advanced cases with a generous diet. Goldberger also cured and prevented the seasonal appearance of pellagra in lunatic asylums and orphanages by increasing the quantity of meat and milk; previously the diet had been deficient in these respects. Goldberger, by the offer of a free pardon from the Governor of Mississippi, was enabled to obtain eleven convicts as volunteers for a feeding experiment to determine if pellagra could be produced by an unbalanced diet in healthy white men. The "pellagra squad," as they were called, were fed on white wheat flour, various maize preparations, polished rice, sugar, sweet potatoes, pork fat, cabbage, and turnip-tops. The food had an energy value of 2950 Calories, and was amply sufficient in this respect, but after the second month on this diet the men complained of weakness, headache, abdominal pain, and other minor discomforts. After five months six of them developed a rash which was pronounced by experts to be identical with that seen in pellagra, and during the last four weeks all the prisoners had shown marked loss of weight and were much out of health. Pellagra would probably have developed in the remainder, but the experiment had to be abandoned owing to the refusal of the men to continue. A control was carried out at the same time; their diet contained some meat, eggs, and buttermilk; there was not a single case of pellagra and no progressive loss of body-weight.

These and other facts clearly point to the diet as the controlling factor in the cause and prevention of the disease. The determining factor seems to be the quality of the protein. Good evidence on this point has been furnished by Wilson, of Cairo. In 1916 pellagra broke out in a camp for Armenian refugees at Port Said. Wilson showed that the diet at first supplied was inadequate both in energy supply (2200 Calories) and in protein supply; indeed, 92 per cent. of the protein was of vegetable origin—three-quarters from wheat and one-quarter from maize.

By determining the least daily amount of a protein required to keep a man from loss of body protein, Thomas was able to assign a series of values to proteins representing their biological efficiency. The *comparative* values according to the quantity required to maintain a man without loss of nitrogen and body-weight were:

Ox-meat ...	104	Rice	88
Cows' milk ...	100	Potato	79
Fish	95	Peas	56
Casein	70	Wheat-flour ...	40
		Maize-meal ...	30

The biological value of meat is therefore three times that of maize. Wilson calculated that the diet as given to the refugees was equal to 22 gm. of

casein. On improvement to a casein equivalent of 41 gm. no more cases of pellagra occurred.

Chick and Hume (1920) succeeded in producing in three monkeys symptoms very like those of human pellagra. The diet was very carefully selected, and was deficient only in respect that it contained no animal protein. One monkey refused the food after a short time; he lost weight and showed signs of incipient pellagra. The second monkey also lost weight, but the loss was lessened by adding tryptophan, though the addition of other amino-acids lacking in maize had no appreciable effect. This monkey had signs of pellagra, and was cured by giving a normal diet. The third monkey had its loss of weight arrested by including tryptophan and hexone bases. This monkey showed some of the characteristic symptoms of pellagra, such as the symmetrical bilateral rash.

It appears thus that pellagra is caused by a continuous shortage in the supply of certain amino-acids in the food. A diet containing animal protein in small quantities will supply the needful amino-acids, but a large supply of vegetable protein may not be equally efficient.

The Cawthron Institute, Nelson, N.Z.

THE building and grounds in which the staff of the Cawthron Institute of Scientific Research has commenced its work were formally opened on Saturday evening, April 2, by his Excellency Lord Jellicoe, Governor-General of the Dominion of New Zealand. The building is a fourteen-roomed house, formerly the residence of the late Mr. John Sharp, and has been fitted up with chemical and biological laboratories, a library, a museum, and offices. The grounds provide room for a considerable amount of investigational work, but an experimental orchard and a site for an arboretum have been secured elsewhere. After being shown over the building by the trustees and staff, Lord and Lady Jellicoe adjourned to the School of Music, where a very enthusiastic gathering of citizens awaited them.

In opening the proceedings the chairman of the Trust, the Lord Bishop of Nelson, gave a short *résumé* of the events which led to the founding of the institute under the will of the late Mr. Thomas Cawthron, and explained the nature of the difficulties which had been met in attempting to carry into effect the provisions of the will. He also stated that the trustees had been fortunate in securing the unique entomological library of Dr. David Sharp, the editor of the *Zoological Record*.

Lord Jellicoe, in declaring the institute open, emphasised the importance of the co-operation of the workers in pure science with those engaged in industry. He had seen sufficient of the Cawthron Institute and its staff to convince him that the work carried out in the institute would be of very great value indeed.

An account of the work of the staff was then given by the director, Prof. T. H. Easterfield, who stated that the staff had been working steadily for about eight months. In the chemical laboratory Mr. Rigg, the soil chemist, had obtained sufficient data for the preparation of a preliminary soil-map of the Waimea district, and this was already being eagerly examined by the farmers and fruit-growers of the district. A careful comparison of the chemical constituents of New Zealand mineral oils from various sources had been made by Mr. McClelland. Dr. R. J. Tillyard, the chief biologist, had paid much attention to the question of the control of plant diseases both by inoculation and by the use of natural enemies of insect pests. He had been successful in establishing *Aphelinus mali*, one of the enemies of the woolly aphis. Several entomological papers by Dr. Tillyard and Mr. Alfred Philpott, the assistant entomologist, were already in the press. The relation of hawthorn hedges to the spread of fire-blight and other plant diseases had also been the subject of close inquiry. Dr. Kathleen Curtis, mycologist to the institute, was working out the life-history of several fungoid diseases under New Zealand conditions, and the work was being followed with great interest by the fruit- and tomato-growers. The rapidity with which the building had been converted into a convenient research institute was very largely due to the energy and effectiveness of the curator, Mr. W. C. Davies, whose arrangement of the museum was admirable.

The director announced that during the week following the official opening the institute would be thrown open for four afternoons and one evening, and that the staff would explain the various activities to the public. More than a thousand visitors took advantage of the opportunity to visit the institute.

Institute of Historical Research in London.

THE opening of the new Institute of Historical Research of the University of London in Malet Street, close to the British Museum, on July 8 is a notable event on which warm congratulations may be tendered to the University and to Prof. Pollard. London University has always led the van in the recognition of research, and the new institute is to be devoted to the extension of knowledge. The inauguration of the building has been happily made the occasion of an Anglo-American Conference of Professors of History. London University, a pioneer in so many directions, created in 1920 the first post in England for the history of medicine. We have already referred to the systematic courses in the history of science that are being developed at University College, and it was in harmony with this London tradition that a sectional meeting of the congress was held on Wednesday, July 13, to discuss "Anglo-American Co-operation in the Publication of Documents and Results of Research on Medieval Science and Thought." The meeting was well attended, and the chair was taken by Mr. A. G. Little, who spoke of the immense amount of important medieval material by English writers still waiting to be edited. He emphasised the need of scholars keeping in touch with one another's work.

Dr. Singer spoke of the educational value of the history of science and of the advantages accruing both to professor and student when to specialised research in a purely scientific field is added a general training as a qualification for a degree. Mr. Charles Johnson, of the Public Record Office, suggested that the editing of a text formed an excellent training for historical research, and suggested that such work, carried

out for incorporation in the publication of a more experienced scholar, should qualify for a degree. Prof. Tout, of Manchester, while a keen advocate of degrees by research and of the organisation of such research, warned the meeting of the dangers of over-centralisation swamping the student's individuality and power of initiative. Dr. G. G. Coulton, though agreeing that this would be a calamity, pointed out that in Cambridge the thesis was a successful part of the curriculum, and expressed the opinion that with due care the organisation of research was wholly advantageous.

Mrs. Singer briefly described the method of her Catalogue of the Early Scientific Manuscripts in the British Isles, and the assistance it gave to researchers in the history of science, especially to those living far from great libraries. She mentioned that a group of American professors was anxious to utilise the mathematical section for a complete *catalogue raisonné* of the mathematical texts, but that they had so far failed to raise from their universities the sum necessary for transcriptions from the manuscripts. She suggested that if other American universities cared to join in this work it would facilitate the raising of funds. After further discussion a resolution was proposed by Mrs. Singer, seconded by Prof. Tout, and unanimously carried, expressing the hope that the Institute of Historical Research would establish a bureau of texts needing to be edited and of students anxious to undertake such work.

University and Educational Intelligence.

ABERDEEN.—The summer graduation ceremony of the University was held on July 14 in the Mitchell Hall of Marischal College. Degrees to the number of 4 honorary and 145 ordinary were conferred by his Grace the Duke of Richmond and Gordon, Chancellor of the University. Sir George Carmichael, Chief Secretary to the Government of Bombay, and Prof. W. M. Bayliss received the Doctorate of Laws.

EDINBURGH.—At the graduation ceremonial on July 14 the following degrees were conferred:—*Honorary Doctor of Laws:* Mr. John Alison, Headmaster of George Watson's College; his Grace the Duke of Atholl; the Lady Frances Balfour; Mr. Ernest Barker, Principal of King's College, London; Sir John Cowan, Edinburgh; Sir A. W. Currie, Principal and Vice-Chancellor of McGill University; the Right Hon. Sir G. E. Foster, Minister of Trade and Commerce, Canada; Dr. J. S. Haldane; the Right Hon. Sir R. S. Horne, Chancellor of the Exchequer; the Right Hon. T. B. Morison, Lord Advocate; Sir Nil Ratan Sircar, lately Vice-Chancellor of the University of Calcutta; and the Right Hon. Sir Robert Stout, Chancellor of the University of New Zealand. *Doctor of Science:* F. A. E. Crew—thesis, "Contributions to the Study of Sex-determination in the Anura"; E. S. Edie—thesis, "Biochemical Researches"; R. J. S. M'Dowall—thesis, "A Study of the Pulmonary Circulation"; V. E. Parke—thesis, "Specific Heat of Constant Pressure of Hydrogen, Nitrogen, etc."; B. B. Sarkar (Calcutta)—thesis, "Relation between Thyroid and Bone-marrow"; J. Waterston—thesis, "Contributions to Medical and Economic Entomology"; and D. Clouston—thesis, "The Improvement of Cotton Crop in Central Provinces and Berar, and Documents relating thereto" (*in absentia*). *Doctor of Philosophy in the Faculty of Science:* Dr. H. Briggs (Birmingham)—thesis, "Mine Rescue Apparatus and Certain Problems bearing thereon"; Mabel Carmichael (St. Andrews)—thesis, "Electro-synthesis in the Series of Dibasic Acids"; A. R. Normand—thesis, "The Boiling Points of Solutions in Methyl Alcohol under Reduced Pressure"; H. M. Steven—thesis, "The Biology of the Chermes of Spruce and Larch, and their Relation to Forestry"; and Margaret P. White—thesis, "Characteristic Frequencies in Elements of Low Atomic Weight (J Series)."

GLASGOW.—At a recent meeting of the University Court it was announced that the Bellahouston Trustees of Glasgow had made a grant of 500*l.* to the University for the purchase of apparatus required for the department of physiology.

An ordinance for the establishment of the ordinary, as well as the honours, degree of B.Sc. in pure science, under new regulations, has been approved by his Majesty in Council, and will come into operation at the beginning of next session.

Mr. A. Stevens, interim lecturer in geography during the absence of Dr. Falconer, has been appointed lecturer in place of the latter, who has now resigned office.

Prof. F. O. Bower, president of the Royal Society of Edinburgh, has been appointed by the Court a Governor of the West of Scotland Agricultural College.

The building operations for the erection of the new Institute of Zoology, adjoining the Natural Philosophy Institute, have been begun. The estimated cost of the structure is 110,000*l.*

The School of Pharmacy established by the Royal Technical College has been recognised under the affiliation scheme for the purposes of the ordinance for the degree of B.Sc. in pharmacy.

MANCHESTER.—The following appointments have been made:—Senior lecturer in physics, Dr. E. C. S. Dickson; senior lecturer in engineering, Mr. C. M. Mason; lecturer in engineering, Mr. Eric Jones; lecturer in systematic surgery and assistant to professor of systematic surgery, Mr. W. H. Hey; lecturer in clinical surgery and assistant to professor of clinical surgery, Mr. Charles Roberts; lecturer in pathology, Dr. Arnold Renshaw; lecturer in bacteriology, Mr. J. H. Dible; lecturer in morbid anatomy and histology, Mr. B. J. Ryrie; and lecturer in psychology, Mr. R. H. Thouless.

IT is announced that Mr. R. A. Bartram has given the sum of 10,500*l.* to Sunderland Technical College. Of this sum 4500*l.* goes to the building fund for the erection of a drawing office for naval architecture at the college and 400*l.* for its equipment; the remainder, 5600*l.*, will be used to establish an endowment fund for four scholarships in naval architecture.

IT has been pointed out to us with reference to the statistics given on p. 555 of our issue of June 30 in the article on "University Statistics of the United Kingdom, 1919–20," that the University of Bristol draws a considerable number of students from countries outside the British Empire. The number of such students shown in the official returns is fourteen, including three from foreign countries, but to these may be added the corresponding figures thirty and twelve relating to the Merchant Venturers' Technical College, as these are all members of the Faculty of Engineering of the University.

Calendar of Scientific Pioneers.

July 21, 1575. Francesco Maurolico died.—The first of the mathematicians of the Renaissance to study optics, Maurolico was born at Messina and became Abbot of Sta Maria del Porto, in Sicily. His chief work was one on conic sections.

July 21, 1888. Henry Carvill Lewis died.—Known for his glacial studies in the United States and Great Britain, Lewis held the chair of geology in Haverford College, U.S.A.

July 21, 1901. Henri de Lacaze-Duthiers died.—The founder and editor of the *Archives de Zoologie*, Lacaze-Duthiers was the originator of the Marine Zoological Laboratories at Roscoff and Banyuls-sur-Mer, and was known for his important studies of marine invertebrates.

July 22, 1802. Marie François Xavier Bichat died.—One of the greatest of anatomists and physiologists, Bichat was only thirty years of age when he died. Trained under Desault, he became physician to the Hôtel Dieu, where Napoleon caused a memorial to Desault and Bichat to be placed. Bichat's most important works were his "Recherches Physiologiques sur la vie et la mort" (1800) and "Anatomie Générale" (1801).

July 22, 1826. Giuseppe Piazzi died.—Piazzi was the first director of the Palermo Observatory, where on the first day of the nineteenth century he discovered the first of the minor planets called by him Ceres, in allusion to the titular goddess of Sicily. In 1814 he published an important catalogue of 7646 stars.

July 23, 1773. George Edwards died.—Edwards made valuable contributions to the ornithology of his day, and in 1750 received the Copley medal for his book entitled "A Natural History of Birds."

July 23, 1916. Sir William Ramsay died.—Born at Glasgow on October 2, 1852, and educated at Glasgow and Tübingen, Ramsay from 1881 to 1887 was Principal of University College, Bristol, and then succeeded Williamson as professor of chemistry in University College, London. He did important work in many branches of physical chemistry, and became famous the world over for his researches on argon and other rare gases of the atmosphere, the discovery of terrestrial helium, and his investigation of radium emanation. He was knighted in 1902.

July 25, 1903. Mathieu Prosper Henri died.—Prosper Henri and his brother Paul (1845–1905) were from 1868 onwards assistant astronomers at the Paris Observatory, where they had an important share in the development of the great International Photographic Chart of the Heavens inaugurated by Gill and Mouchez.

July 27, 1759. Pierre Louis Moreau de Maupertuis died.—A native of St. Malo and a member of the Paris Academy of Sciences, Maupertuis, who visited London in 1727, the same year as Voltaire, was the first in France publicly to support the views of Newton. With Clairaut he assisted in the measurement of a degree of meridian in Lapland, and afterwards, on the invitation of Frederick the Great, became president of the Berlin Academy of Sciences.

July 27, 1844. John Dalton died.—Born in Cumberland in 1766, Dalton from boyhood was engaged in teaching, and for the last fifty years of his life was connected with the Manchester Literary and Philosophical Society. His meteorological studies and his investigation of gases and vapours led to his discovery of the law of thermal expansion of gases and to the enunciation of the atomic theory. In 1808 he published his "System of Chemical Philosophy." After the death of Davy he was elected one of the eight foreign associates of the Paris Academy of Sciences.

E. C. S.

Societies and Academies.

LONDON.

Aristotelian Society, July 4.—Prof. G. Dawes Hicks, vice-president, in the chair.—Dr. F. C. S. **Schiller**: Arguing in a circle. A scientific system is essentially *partial*. Being constructed by selections and exclusions and relative to a purpose, it contains no warrant for the postulation of any all-embracing system. Objections to a system cannot be met by arguing within it. To meet a challenge it must obtain outside support. If it is to give satisfaction it must not close itself, but remain open to correction. The sciences are such systems, and so escape the charge of circularity. An all-embracing system is not a valid ideal, because inability to select would reduce it to chaos, while if logically complete it could be rejected as a whole. Also it is self-contradictory, for either it can be enlarged to satisfy objections, and then it is not all-embracing, or it cannot be enlarged, and then it argues in a circle. If it presupposes relativity to purpose, it cannot reach absoluteness. The attempt to base inference on implication within an ideal system is no improvement on formal logic, but merely a half-way house to a complete surrender of the notion of "formal validity."

PARIS.

Academy of Sciences, June 27.—M. Georges Lemoine in the chair.—M. **Riquier**: The complete families of integral figures of a system of partial differential equations of the first order.—J. **Kampé de Fériet**: Systems of partial differential equations of the most general hypergeometrical functions.—M. **Hadamard**: Systems of partial differentials, comprising as many equations as unknown functions.—T. **Varopoulos**: A class of transcendental functions.—M. **d'Ocagne**: Lines of curvature of quadrics.—J. **Andrade**: The problem of starting (a chronometer), and sustained pendular movements.—A. **Thuloup**: The equilibrium and stability of elastic apparatus.—F. **Quénisset**: Photographs of the planet Venus. On February 23, 1921, an observation with the 24-cm. equatorial showed a marked grey spot on the edge of the planet near the centre. Seventeen photographs were immediately taken with varying exposures, and a diagram is shown giving the appearance of the planet as taken from these negatives.—M. **Juvet**: The formulæ of Frenet for a Weyl space.—L. **de Broglie** and A. **Dauvillier**: The electronic structure of the heavy atoms. A comparison of the physico-chemical indications concerning the electronic structure of the elements with those furnished by a study of their X-ray spectra.—G. **Ranque**: A new mercury pump. A circulating mercury pump, requiring only 400 grams of mercury, worked with an auxiliary water pump.—M. **Chevenard**: Relation between the anomalous expansion and thermal variation of magnetisation of ferromagnetic bodies.—R. **Dubrisay**: The action of boric acid on glycerol and the polyvalent alcohols. The application of a new physico-chemical volumetric method.—E. L. **Dupuy**: The influence of welding on the resistivity of iron. The presence of ferric oxide in the metal causes an increase in the electrical resistance.—MM. **Dervin** and **Olmer**: Ammoniacal silver carbonate. This is formed by the action of atmospheric carbon dioxide upon an ammoniacal solution of silver oxide. It forms colourless hexagonal crystals, and has the composition $Ag_2CO_3,4NH_3,H_2O$.—E. **Decarrière**: The *rôle* of the gaseous impurities in the catalytic oxidation of ammonia. Details of a study of the effects of hydrogen sulphide as impurity in the ammonia.—L. **Lutaud**: General remarks on the tectonics of the pre-Riffian zone of northern R'arb,

Morocco.—S. **Stefanescu**: The phylogenetic and evolutive value of the lamellar formulæ of the last molars, $M\frac{1}{1}$, $M\frac{2}{2}$, $M\frac{3}{3}$, of mastodons and elephants.—C. **Störmer**: The aurora borealis of May 13, 1920. Simultaneous photographs from pairs of stations formed a basis for calculating the heights of various points of the aurora. The distances from the earth were between 192 and 470 kilometres.—E. **Delcambre** and Ph. **Schereschewsky**: A new method for predicting barometric variations.—A. **Guilliermond**: The microsomes and the lipoid formations of the plant cell. The microsomes appear to be simple products of cell metabolism. They are usually constituted by lipoids, sometimes with neutral fats. Hence the terms microsome and spherome are unsuitable, and should be replaced by lipoid granulations.—E. **Couvreur** and P. **Chosson**: The mode of action of plant rennets.—S. **Tchahotine**: The microscopic radiopuncture of mobile cells.—J. **Lopez-Lomba** and P. **Portier**: The physiological mechanism of the resistance of the rabbit to avitaminosis. Adult rabbits resist indefinitely a diet sterilised at a high temperature; this appears to be due to the bacteria which normally develop in the lymphoid tissue, these providing the vitamins missing from the food.—A. **Dehorne**: The mechanism of somatic metaphase and anaphase, and its consequences in *Corethra plumicornis*.—A. **Weber**: Grafts of the eggs of tritons in the peritoneal cavity of salamanders.—A. **Labbé**: The evolutive cycle of *Dunaliella salina*.—Mlle. Lucienne **Dehorne**: Conditions of the development of the durable egg in Phyllopods.—A. Ch. **Hollande**: The presence of a new Spirochætoid, *Cristispirella caviae*, with well-developed undulating membrane, in the intestine of the guinea-pig.—P. **Courmont**, A. **Rochain**, and F. **Laupin**: The purification from bacteria and the coli bacillus in the course of treatment of sewage by the activated sludge method.

Rome.

Reale Accademia nazionale dei Lincei, April 17.—F. D'Ovidio, president, in the chair.—Papers by fellows:—C. **Segre**: Principal lines of a surface of S_5 and a characteristic property of Veronese's surfaces, ii. In S_{2k+1}, when k is even the infinitesimal order of contiguity of two S_k's is always odd.—F. **Severi**: Theory of simple integrals of first species belonging to an algebraic surface, iii. Every Abelian function of the body "omega" is a holomorphic or meromorphic function of y about every value which is neither singular nor critical.—A. **Abetti**: Applications of vectorial calculus to astronomy. Two formulæ are obtained agreeing with those of Chauvenet for the annual precession in longitude.—A. **Angeli** (fellow) and A. **Pieroni**: A work by Prof. E. Salkowski on melanin.—Papers communicated through a fellow:—O. **Lazzarino**: Limiting motions of a semi-rigid body about a fixed point under no forces. A continuation of previous work on motion of a solid with cavities containing viscous liquid. The ultimate motion is what one would necessarily expect.—M. **Pascal**: Superficial circulation, iii. Expressions for the force of sustentation in the case of a fluid current in space. The expressions for the force components of sustentation represent a generalisation of the ordinary hydrodynamical problem from two- to three-dimensional motions.—E. G. **Togliatti**: Three-dimensional varieties of fourth order which are loci of at least "infinity squared" straight lines, i.—L. **Pieragnoli**: Pathology of Pliocene and post-Pliocene mammals of Tuscany. Specimens in the museum at Florence of *Equus stenonis*, *E. caballus*, Cervus (sp.), *Rhinoceros etruscus*, and *Bison priseus* show various lesions, but without traces of tuberculosis except in one bone of Cervus. The specimens in question mostly came from Valdarno. The author compares these results with the remains from Equi, in which tuberculosis was prevalent in *Ursus spelaeus*, while the lesions of the Florentine remains were there lacking.

May 2.—V. Volterra, vice-president, in the chair.—Papers by fellows:—A. **Angeli**: "Various observations" (action of pyridin on nitric ethers, coagulation of solutions of nitro-cellulose, production of certain sparks, experiments to show explosive properties of certain nitro-derivatives).—C. **De Stefani**: Ligurian fossil sponges, vi.: Internal strata of the western crystalline zone (Costa di Sant' Alberto, Voltri Station, Mele, Campo Ligure).—L. **De Marchi**: Vertical temperature gradient in the atmosphere. A modification of the usual thermodynamic formula in order to meet certain objections.—G. **Fubini**: Projective theory of congruences W.—F. **Severi**: Integrals of first species, iv.—G. **Bruni**: A new process for the cold vulcanisation of rubber. The specification refers to the process of generating the thiocarbanilide or other accelerator by a chemical reaction within the mass of rubber to be vulcanised instead of adding it in its final form. The author also cites an analogous process described in America by Scott and Bedford, who, however, use another accelerator.—In the next paper, communicated by Bruni, E. **Romani** shows that bisulphide of thiouramine is capable of vulcanising rubber even without the addition of free sulphur, a result not recorded by the American writers.—Prof. Volterra announced the death on April 16 of Prof. Gino Galeotti.

Lahore.

Philosophical Society, October 15, 1920.—Dr. B. Sahni, president, in the chair.—G. S. D. **Ahluwalia**: The prevention and cure of plant diseases.

November 24, 1920.—Dr. B. Sahni, president, in the chair.—C. V. **Raman**: Ripples.

December 13, 1920.—Dr. B. Sahni, president, in the chair.—M. L. **Bhatia**: Some observations on the Lahore centipedes.

March 14, 1921.—Dr. B. Sahni, president, in the chair.—N. A. **Yajnik** and D. R. **Sarma**: Some investigations on indigo textile hydrosulphite vat-dyeing. As a result of careful investigations it was found that indigo can be best reduced by hydrosulphite NF in alkaline medium ranging from 0·1 per cent. to 5 per cent. NaOH in the ratio of 1 : 1·5 by weight. Unfavourable influence of the slight excess of free alkali in the vat can be to a great extent controlled by the addition of acetic acid, boracic acid, etc., and it was found that very small quantities (up to about 1 per cent.) of these gave greater absorption coefficient and better shades. The nature of the action is not yet clearly understood, but the effect of these additions is likely to be of great technical importance.

March 21.—Dr. B. Sahni, president, in the chair.—A. **Chandra**: Chemical constitution and optical activity, with special reference to camphor-amide derivatives.—B. K. **Singh** and M. **Singh**: 1 : 4-Naphthylene bisiminocamphor. This substance possesses the highest rotatory power hitherto observed.—B. **Sahni**: The cuticular structure of *Glossopteris angustifolia*, Brongn. From the form and venation alone it is so difficult to distinguish *G. indica*, Schimp., and *G. angustifolia*, Brongn., that the specific distinctness of the two has been doubted. The structure of the cuticle of *G. indica* was described by Zeiller in 1896; that of *G. angustifolia* now investigated shows well-marked differences which help to establish the two forms as distinct species.

May 19.—Dr. B. Sahni, president, in the chair.—B. I. **Das**: Sidelights on modern science from the

ancient sastras.—N. A. **Yajnik** and H. C. **Mahajan**: Hydrolysis of some Indian oils by vegetable lipase. The following oils were tried: (1) Linseed oil, (2) soapnut oil (from the seeds of *Sapindus trifoliatus*), (3) sukh-chain oil (from the seeds of *Pongamia glabra*), (4) neem oil (from the seeds of *Melia azadirachta*), and (5) sesamum oil. Of these sukh-chain oil and soapnut oil were not pressed so far from their seeds, but were specially extracted for the purpose of investigation, and they were found to be of particular interest on account of the extent to which they can easily be hydrolysed.

British Dyes and Dyestuffs.

THE Sub-committee appointed on December 2, 1919, by the Standing Committee on Trusts to "ascertain to what extent supplies, prices, and costs of dyes and dyestuffs in this country, and profits thereon, are affected by any trade combination" has now reported under date May 18, 1921. The Report (Cmd. 1370, 4*d.* net) comprises fifty-five clauses, from which are drawn twenty conclusions, these being widely traversed in a minority report presented by Major Harry Barnes, M.P.

The first fourteen clauses reveal nothing which is not already familiar to those who have given more than superficial attention to the subject. A synopsis of the factors which had placed this country in a position of such complete inferiority to Germany as that which existed prior to the war brings out from their stable the two familiar stalking-horses, patent law and industrial alcohol.

"Further to these it has been said that in the early days there was a certain slackness and a lack of organisation on the part of the British manufacturers, who were content, for instance, to send out circulars whilst the Germans sent out travellers who were not only salesmen but skilled chemists; and it is asserted that the whole course of the development of synthetic dyes in this country subsequent to the initial discovery exhibits a lack of properly directed scientific research. But whether these were contributory causes of the passing of the dyes industry out of this country, or whether they were accompaniments or results of the heavy handicap of unfair patent arrangements and unintelligent prevision as regards the use of industrial alcohol, is a matter on which there are differences of opinion" (clause 3).

This lengthy passage has been quoted because it offers an example of the confused thinking which it appears to be the fate of the dye-making industry to receive. Moreover, it is characteristic of the whole Report, which studiously avoids arriving at a conclusion that is not open to contradiction elsewhere in its pages; Major Barnes is more direct. Thus the Sub-committee is unable or unwilling to determine the relative value of the contributions to the industry made by duty-free alcohol on one hand, and by "properly directed scientific research" on the other. Perhaps it was not represented to the Committee that if the textile manufacturers of the sixties of last century had possessed imagination enough to set aside only 1 per cent. of their profits to develop what might then have been regarded as a branch of their own industry, Hofmann, Brunck, Caro, Martius, and Böttinger need never have left this country to build up the chemical industry of Germany, and a brisk demand for young chemists might have led Oxford and Cambridge then to weigh their responsibility towards that branch of knowledge which underlies all modern industry and all forms of life.

This nice reluctance to face an issue characterises also the treatment accorded by the thirteen agreed members to the main question upon which their deliberation was invited—namely, the extent to which the supply and cost of dyes have been affected by "any trade combination," otherwise the British Dyestuffs Corporation. Rightly declaring that "If the Corporation is over-capitalised its ability to sell at a reasonable price, while making a reasonable profit, will be in so far diminished" (clause 17), the Committee proceeds to analyse the financial basis of the amalgamation between British Dyes, Ltd., and Messrs. Levinstein which followed from the rejection in August, 1918, by the shareholders in the former company, of the alternative scheme proposed by the board of directors. The analysis recalls the fact that, the nominal capital of Messrs. Levinstein having been divided into 3000 preference shares (10*l.*) and 6000 ordinary shares (10*l.*), the preference shareholders received in exchange preference shares in the Corporation of an equal nominal amount, or cash at their option.

The holders of ordinary shares were more fortunate. The valuation of the net assets available for distribution to them showed a total of 348,000*l*., and for this they received 174,000*l*. of 7 per cent. preference, 174,000*l*. of 8 per cent. preferred ordinary, and 450,000*l*. of 8 per cent. deferred ordinary shares, the last-named representing "goodwill, patent and other rights." Evidently the Sub-committee felt that such generosity requires an explanation, particularly as "It has been alleged that for fifteen years before the war Messrs. Levinstein's had not paid a dividend"; but the members were satisfied with the reflection that "the policy of the company had in general been not to pay out profits in dividends, but to put the profits back into the business" (clause 21). Fifteen years' abnegation of all dividends would certainly appear to merit recompense, but the fact that the present market valuation of the 798,000*l*. scarcely exceeds 100,000*l*. is a curious comment on the propriety of the original allocation. "The net value of the assets of British Dyes, Ltd., showed a total of 1,143,580*l*. available for distribution to the ordinary shareholders, and this was satisfied as to one-half by the issue of preference shares and as to the other half by the issue of preferred ordinary shares in the Corporation. In addition, the shareholders in British Dyes, Ltd., were entitled to an issue of 550,000 deferred ordinary shares in respect of goodwill, patent and other rights" (clause 20). Thus 1,000,000*l*. of deferred ordinary shares were created, adding 80,000*l*. per annum to the interest charges.

The Report is not so clear as to the allocation made to the Government. The statement that "The Government subscribed for 850,000 preference and 850,000 preferred ordinary shares in substitution for the loan on debentures to British Dyes, Ltd., of 1,700,000*l*. to which they were committed" (clause 10), does not reveal the proportion of the 1,700,000*l*. which had been loaned to British Dyes, Ltd.; the sum mentioned is that "to which they were committed," and it has not been publicly stated that the amount actually loaned was in excess of 1,200,000*l*. Remembering that the Government debenture was at 4 per cent., and that the average nominal rate of the preference and preferred ordinary shares is 7½ per cent., it will be recognised that this allocation represented an additional interest charge of at least 60,000*l*. per annum on the earning capacity of the Corporation.

Conclusion (7), nevertheless, states that the thirteen agreed members "do not consider that the Corporation is under the handicap of over-capitalisation, except in so far as the buildings, plant, etc., of the British Dyestuffs Corporation, Ltd., were erected at a time of high prices and feverish conditions," whilst Major Barnes's conviction is that "the Corporation is over-capitalised, and the Government, before investing public monies in same, should have insisted on the buildings and plant provided out of the abnormal war profits being written down to pre-war costs." Those who have difficulty in deciding between these conflicting opinions may be assisted by the recollection that the German companies, with which the Corporation must ultimately find itself in competition, have consistently practised the policy of under-capitalisation by returning a large proportion of their profits to the business in the form of expenditure on development and research. The Sub-committee is silent on this point. One of the inducements to potential subscribers offered by the prospectus of the British Dyestuffs Corporation in 1919 was a synopsis of the profits earned by the German "Big Four" during 1913, showing 2,499,592*l*. to have been the fruit of share capital and reserves aggregating 9,886,318*l*.; owing to the prudent policy indicated above, however, the nominal ten millions were notoriously nearer twenty millions in actual value, thus reducing the profit to the neighbourhood of 12 per cent., which is not an excessive figure for an industry which was virtually a world-monopoly.

In addition to the capital inflation indicated above, one most regrettable feature of the amalgamation was the destruction of the co-operative character of British Dyes, Ltd. Shareholders in that company were confined to dye-users, and the rate of interest was limited to 6 per cent. so long as the Government debenture remained unredeemed. Consequently, there was no inducement to charge prices higher than would pay this modest interest and provide funds for the prosecution of research and the development of new processes. "The influence of the amalgamation on prices is submerged by the other influences at work, and our attempts to single it out for separate examination have proved fruitless" (clause 39). Nevertheless, the schedule of prices for dyes is a startling contribution to the Report, showing percentage increases in March, 1921, over July, 1914, which are seldom less than 500, and often exceed 1000; but there is no evidence to show that they are in any way due to the combination. That is really the conclusion of the whole matter, and whilst the sessions of the Sub-

committee were doubtless full of interest and information to the members, it unfortunately happens that the Report will not contribute anything substantial towards a solution of the desperate problem with which the country remains confronted.

A War Memorial.

The Scientific Papers of Bertram Hopkinson. Collected and arranged by Sir J. Alfred Ewing and Sir Joseph Larmor. Pp. xxvii + 480 + plates. (Cambridge: At the University Press, 1921.) 63*s.* net.

BERTRAM HOPKINSON'S scientific friends, including his Cambridge staff, decided well when they determined that no memorial could be more suitable or permanent than a collected edition of his writings on mathematical and engineering science. The editors and the syndics of the Cambridge University Press alike have earned our thanks by the manner in which their shares of the publication have been carried out.

There is no need to tell at length the tragic story of his life. Called home from Aden in 1898 by the death of his father, brother, and two sisters on the Dents de Veisivi, he took up his father's work as a consulting engineer with the aid of his uncle Charles, and carried out various important undertakings. Five years later he became professor of mechanism at Cambridge, and in the same year he married. For the next eleven years he was fully occupied in the development of the work of his chair. The papers in the volume under review form his contributions to science during that time, but they do not constitute by any means the whole of the debt we owe to him. To quote from Prof. A. V. Hill's appreciation in the *Alpine Journal,* at Cambridge

"a professor of mechanism can hope to make a school essentially in touch with the traditions of the place only on condition that his interests are largely, if not mainly, scientific. In Hopkinson Cambridge had an ideal professor, and the pupils trained in his school have already, especially during the war, raised a memorial to him by their work."

The war, when it came, claimed him at once, at first as a teacher at Chatham, then at the Admiralty, where he conducted some most important experiments which led to the modern methods of protection of large ships against torpedoes. Finally he joined the Royal Air Force as an officer in charge of experimental work of all kinds, becoming in June, 1918, Deputy Controller of the Technical Department; on August 26 of that year he was killed in a flying accident.

The papers in the volume fall naturally into three main groups, dealing respectively with electrical engineering, with certain metallurgical questions, and with the problems of the internal-combustion engine. In addition, the first paper of the series, one on sources and vortices, which was contributed to the London Mathematical Society in 1898, deserves mention as indicating the width of his knowledge and interests. He was an electrical engineer by profession; his father had placed the construction of electrical machinery on a scientific basis by the paper on dynamo-electric machines written in conjunction with his uncle Edward, and published in the Phil. Trans., and it was not unnatural that the son's early work as professor should deal with similar problems.

His first paper in the Proceedings of the Royal Society on the shunting of alternate-current machines gave a satisfactory explanation of the phenomenon, and seems to have been inspired in part by the behaviour of a small machine in the Wimbledon Power House near his home.

Electrotechnics did not for long retain his main attention. Papers on the elastic properties of steel at high temperatures, brittleness and ductility, and the endurance of metals under alternating stresses of high frequency, followed during the next few years, and each served to bring out his versatility and his power of getting at the heart of a subject and of explaining in clear and concise language the results of his investigations.

Two remarkable papers on the magnetic properties of iron and its alloys in strong magnetic fields, and on manganese steels, were published with Sir Robert Hadfield in 1911 and 1914, and have added greatly to our knowledge of magnetism. Hopkinson was able to show that the magnetism of saturation might, in the case of the carbon steels, be predicted from the composition by treating each steel as a mixture of iron and of less magnetisable carbide. With manganese, however, no such simple relation was found to follow.

The work, however, by which Hopkinson will probably be best remembered is that on the internal-combustion engine. It began with a British Association paper in 1904, which led in 1907 to an investigation into the efficiency of the gas engine; in the course of this research the well-known Hopkinson indicator was developed, and it was shown that indicator diagrams, properly drawn, could be used satisfactorily for the measurement of efficiency. In 1906 a most im-

portant paper on the distribution of temperature in an explosion cylinder was communicated to the Royal Society, and the discussion aroused on these matters led to the formation of the Gaseous Explosions Committee of the British Association, of which Sir Dugald Clerk was chairman, and Hopkinson secretary. Much, probably most, of our recent knowledge of the theory of the internal-combustion engine has sprung from the labours of that committee, and to the advance made Hopkinson was a most important contributor. It is sufficient, perhaps, to mention his last paper on the subject, "On Radiation in a Gaseous Explosion," communicated to the Royal Society in 1910; the work thus begun has recently been brought to a most satisfactory conclusion by his pupil and assistant, Mr. W. T. David. In conclusion, reference should be made to a lecture at the Royal Institution, 1912, on "The Pressure of a Blow," and to the Royal Society paper on "A Method of Measuring the Pressure due to the Detonation of High Explosives," which led in a simple way to results of marked interest.

Enough has probably been written to show the high value of the work Hopkinson did, and the magnitude of the loss to engineering science caused by his early death. To quote the words of Sir J. J. Thomson, speaking as Master of Trinity in a commemorative address, "our roll of honour contains the name of no one who has rendered greater services to his country."

The New Medicine.

The Principles of Preventive Medicine. By Prof. R. T. Hewlett and Dr. A. T. Nankivell. Pp. viii+536. (London: J. and A. Churchill, 1921.) 21*s.* net.

THE object of Prof. Hewlett and Dr. Nankivell in writing this book was to give an outline of the principles and practice of preventive medicine "so far as it seems to concern the medical student and the general practitioner of medicine." That there was need for such a book there is no doubt. All who are concerned in any way with the teaching or practice of public health and preventive medicine certainly must agree that such a book was required, just as they must agree that this volume by Prof. Hewlett and Dr. Nankivell goes some distance towards supplying the need. The preparation of the book, the authors admit, gave considerable trouble, the extent of the field to be covered rendering it difficult to decide what to include and what to omit. In all book-making this is always a difficult thing, but in this case the authors have chosen wisely, and in the twenty-one chapters and three appendices they appear to have made reference to all the more important matters in respect of which the medical student and the practitioner—who, after all, are expected to play a great part in the preventive medicine of the future—need information.

As might be expected in a book prepared by two practical men like Prof. Hewlett and Dr. Nankivell, one a distinguished bacteriologist, and the other a Medical Officer of Health of some years' standing, the information given is trustworthy. Here and there in the writing, however, there is shown a tendency to leave the lines followed in the ordinary medical books, and to indulge in what may almost be called "flights of fancy." In a number of places the authors appear unable to avoid the temptation to drop into poetry, and to provide word-pictures in which they use much more colour than appears to be essential in a book intended for such dispassionate readers as medical students and practitioners are, or should be. The chapters in which the fancifulness and the overdrawing are most frequently to be met are, curiously enough, those in which serious writing and strict accuracy of expression are most called for—viz. those dealing with housing, infancy, motherhood, and school children—and though there may be some who will appreciate the picturesque and exaggerated phrasing at its true value and find it helpful, it seems not unlikely that more will regard it as objectionable and out of place. In any case, it seems unfortunate that in one of the first books on preventive medicine the line here chosen should have been taken, and the impression given that the subject is one which is most suitably dealt with in a style more popular than scientific.

In the chapters dealing with infectious diseases the authors have exercised greater restraint and provided an amount of interesting, useful, and sound information. These chapters are amongst the most valuable in the book, and are particularly noteworthy for a declaration against the tendency to search out and find specific germs of disease, and more or less in favour of the view that, since they can be shown to change their shape and even their virulence on occasion, there is no such thing as constancy among micro-organisms. It is not, therefore, too much to suppose them capable of undergoing such transformations as will allow them to produce one type of disease at one time and another of an associated type at some other time. Another excellent chapter—although by the medical student and practitioner it may be regarded as rather more full of arithmetic and mathematics than is absolutely essential—is that on vital statistics. Amongst readers

who will appreciate it are medical men in practice as Medical Officers of Health, many of whom find guidance in this connection necessary occasionally.

"Hewlett and Nankivell," as the book will inevitably be called, is certain of a great welcome, and equally certain to be classed as good. The feeling cannot, however, be escaped that it would have been better if the authors had avoided the faults in style to which reference has been made. In the second edition, which, no doubt, will soon be required, an opportunity for dropping some of the more lurid of the descriptive matter will occur, and it is to be hoped that the space thus released may be utilised for the presentation of some illustrations in addition to, or even in place of, a number of the charts and diagrams which alone adorn the present edition.

Non-Ferrous Metallurgy.

Handbook of Metallurgy. By Prof. C. Schnabel. Translated by Prof. H. Louis. Third edition, revised by the translator. Vol. i., *Copper—Lead—Silver—Gold.* Pp. xxi+1171. (London: Macmillan and Co., Ltd., 1921.) 40*s.* net.

THIS well-known work on the metallurgy of the non-ferrous metals was first made available to the English metallurgist in 1898 by Prof. H. Louis. At that time there was not, in the English language, a complete treatise on this branch of the subject, and it was at once recognised that the book was an addition to our literature. The fact that Prof. Louis had rendered metallurgists a valuable service receives confirmation in the demand for a third edition. In preparing this new edition, Prof. Louis wisely decided to bring the work up to date himself, and not to wait for the publication of the third German edition, for, as he states in the preface, "all the important modern improvements in metallurgical practices are to be found in English-speaking countries."

A work of this kind, which covers such a wide field, takes considerable time to revise, and the war, having intervened during its preparation, has prevented some of the more recent developments from being recorded; but, in spite of this, the book will be found to be most useful and to have distinct value.

The volume which is now published deals with the metallurgy of copper, lead, silver, and gold. The original form of the work is still maintained, but the previous edition has been increased by about forty-five pages. The actual addition of new matter is greater than is represented by this increase, for obsolete processes have been deleted. Considering the progress made in recent years, it is evident that Prof. Louis has had a difficult task in including the descriptions of modern methods without seriously increasing the size of the volume. For this reason the cutting down of the older processes might perhaps have been somewhat more drastic. Some of the processes described under silver, and also the "chlorination process" for the extraction of gold, have not a wide application at the present time, and are scarcely worthy of the space they have been allowed.

Besides the general revision, the section on calcination furnaces in the part on copper has been extended, the chief furnaces being described; also a concise description of the blast-roasting of copper ores is given, and the section on the Bessemer process of copper extraction has been enlarged. Among the additions made under lead are: The Savelsberg process, blast-roasting without lime, pot-roasting, and down-draught sintering processes. The part devoted to gold has received much attention, and has been improved by a clear and, in the space available, complete account of the cyanidation process--fine-grinding, various methods of classification, and the "all-slime process" being included.

There are two points open to criticism. In regard to the original matter, no indication is given that any of it has become of less practical value; consequently, students may receive the impression that some of the older processes are as important as, or even more important than, some of the chief modern methods. Moreover, the retention of a statement such as "the more recent form of" made in connection with the description of a plant which was given in the first edition twenty-three years ago is liable to be misleading.

The volume, as a whole, is comprehensive and accurate, and can be recommended with confidence. Prof. Louis is to be congratulated on having prepared this new edition and brought the book up to date. It is a pity that most readers will not be able to determine which is really the translator's work and so to judge of its excellence.

E. C.

The Confidences of Men of Science.

The Purple Sapphire, and other Posthumous Papers. Selected from the Unofficial Records of the University of Cosmopoli by Christopher Blayre. Pp. x+210. (London: Philip Allan and Co., 1921.) 7*s.* 6*d.* net.

THE author—or, to be more accurate, the editor—of this fascinating but blazingly indiscreet volume refers to NATURE as "that

admirable journal"—a compliment which ought perhaps to secure a benevolent review, but needless to say we shall not let it induce us to depart from our habitual detachment.

Mr. Blayre was for many years Registrar in a well-known university, and had certain manuscripts confided to him by more or less scientific members of the staff on the understanding that they should remain *in retentis*, as who should say, unless events occurred which rendered their publication desirable. In no case, however, were they to be published in the lifetime of the depositors, to whom the documentation served as a sort of Freudian relief. Now there is no doubt that the publication clears up many puzzling events, such as the ghastly damage that followed the acceptance of the so-called "purple sapphire" by the Mineralogical Museum, the mystery of Prof. Markwand's death, and the tragic case of Austin Black, who, if anyone, must be credited with laying the foundations of psychobiology.

To clear up these and other obscurities, more familiar to the older than to the younger readers of NATURE, has seemed to Mr. Blayre sufficient warrant for publishing the deposited documents. He does not seem to be aware, however, that the Professor of Biology, the present reviewer, is still alive, and by no means so sure as he once was of Mr. Blayre's fiducial discretion. His feeling of relief when he found that his own document had been suppressed by the publishers enables him to sympathise at least with the relatives of the deceased gentlemen whose confidences are now blazoned abroad. It is true that names are sometimes suppressed or modified in the book, but in these days, when the study of the history of science is rife, it seems a cruelly thin disguise to refer to a professor by a pseudonym and then proceed to mention one of his well-known discoveries.

Apart from our own survival, which rather condemns the book, apart, also, from the editor's hurry to disclose the confidences of well-known men of science, we would protest against the somewhat amateurish editing. "Science" was never Mr. Blayre's *métier,* and we see that in his editing. When, for example, was Prof. Tyndall knighted, and how could there possibly be a monkey, even a small monkey, inside a bunch of bananas? Even the date of the preface is wrong; and Lingulella figuring as a Lamellibranch (!) is a very dead fly in the ointment. Would it not have been wiser to have submitted the papers for editorial purposes to the present heads of the various departments concerned, and to have issued them as a volume of "University Studies"?

At the same time, many will be grateful to Mr. Blayre for publishing these papers with their poignant personalities and astonishing intimacies. They have made many obscure things clear, and they show us how human men of science are after all. But it is strange to read nowadays of the timidity with which the Professors of Botany and Zoology regarded the development of the cosmic dust, which is now a common item in the kinematographic repertory.

THE PROFESSOR OF BIOLOGY.

Our Bookshelf.

The Breeding and Feeding of Farm Stock. By J. Wilson. Pp. vii + 152. (London: Methuen and Co., Ltd., 1921.) 6*s.* net.

THIS work attempts to treat of a vast subject within a hundred and fifty pages of medium size and type, and there is no preface or preliminary word denoting that the talented author asks for that indulgence which may be claimed by a purely elementary treatise. So ambitious an endeavour courts criticism, and, in this case, no student of the subject could say that it is undeserved. Even in such a hurried summary a few words might have been spared to warn the tyro when the text was meant to be dogmatic and when the author was merely drawing upon a well-trained imagination. Perhaps the best example of such a caution being needed is to be found on p. 26. Here a truly skilful flight of fancy reads as if there were some scientific evidence to support the writer's faith in his own imagery. The harmful effect of the lack of necessary explanations may be found in sentences which can be described, read as they stand, only as the travesty of truth: *e.g.* we read on p. 65: "Sometimes a breed is recommended because it can live on little food, but, if a breed or an individual cow lives upon little food, then neither the breed nor the cow is a good milker."

Besides such inexactitudes, there are many omissions of reference to work throwing light on problems discussed. Nevertheless the book contains much that is interesting and instructive, and some matter that is inspiring. While it cannot be wished that the present work may be republished in its present epitomised form, it is to be hoped that the author will become more ambitious and give his readers, in a larger volume, or in several, the elaborated results of his study of this very important subject. K. J. J. M.

John Dalton. By L. J. Neville-Polley. (Pioneers of Progress. Men of Science.) Pp. 63. (London: S.P.C.K.; New York: The Macmillan Co., 1920.) 2*s.*

WITHIN the last ten years chemistry has completely emancipated itself from a type of metaphysical obscurantism which seems to be invading

physics in another disguise. Although a scientific atomic theory, as distinguished from the merely poetic efforts of the Greeks, appeared early in the seventeenth century, the chemical atomic theory on which the science is based is unquestionably the work of John Dalton. The story of Dalton has been told before, but the present small memoir may be welcomed as an interesting account which should find favour with students and the general reader.

Very few slips have been noticed. Garnett was Davy's predecessor at the Royal Institution; "Cruickshanks" (p. 28) should be "Cruickshank"; Thenard wrote his own name both as "Thenard" and as "Thénard"—the first was used by his contemporaries, but the second form, used by Mr. Neville-Polley, seems to be common now. It is scarcely correct to describe Thomas Thomson as the "great friend" of Dalton, for at the time of his visit to Manchester to get the account of the origin of the atomic theory accepted prior to Roscoe and Harden's investigations, Thomson was not personally acquainted with its author. The statement that Higgins "assigned the same weight to all atoms" was refuted by Meldrum, whose work should have been mentioned.

Geological Survey of Nigeria. Bulletin No. 1. The Geology of the Plateau Tin Fields. By Dr. J. D. Falconer. Pp. 55+x plates. (Nigeria: Geological Survey of Nigeria, 1921.) 10*s.* net.

IN the first Bulletin of the Nigerian Geological Survey Dr. Falconer has given a useful account of the tin-bearing region of the Protectorate. Ancient schists and gneissose granites have been invaded by newer granites, followed by emanations rich in tin and fluorine but not in boron. Long afterwards, when the country had been worn down by atmospheric agencies, it was covered by the "Fluvio-marine Series"—volcanic rocks, and river gravels often rich in tin. Still later these were succeeded by younger volcanic rocks which have in some cases capped and preserved the older sediments. The alluvial beds that are still in process of formation are, however, the chief source of tin. Their investigation not only furnishes information on the occurrence of alluvial tin, but throws light on the problems of river erosion and deposition. The publication under notice, which is illustrated by excellent photographs of scenery and micro-sections as well as by maps, will be welcomed both by geologists and by mining engineers, though some analyses of the chief rock-types would have been a useful addition.

It is worth consideration whether it would not be possible to supplement a scientific publication like this by a non-technical pamphlet, clearly but simply written without assuming any previous knowledge of the subject. It should be provided with a general geological map, typical views, and large-scale maps and sections, and the meaning of these should be carefully explained. Such publications would go far to promote a more general interest in the study of the rocks and the minerals they contain.

J. W. EVANS.

The Land of Goshen and the Exodus. By Sir Hanbury Brown. Third edition. Pp. 189. (London: Edward Stanford, Ltd., 1919.) 7*s.* 6*d.* net.

THIS extraordinarily interesting account of the bondage of Israel in Egypt and their exodus therefrom, written with the erudition of the scholar and the charm of the non-professional, is issued a third time. Sir Hanbury Brown advocates the view that the land of Goshen lay immediately west of the present Suez Ship Canal, that the western arm of the Red Sea extended at the time of the exodus over the Bitter Lakes and Lake Timsah, almost as far as Tel el Maskhûta (Pithom of the Bible), and that the crossing of the Red Sea took place between Lake Timsah and the Bitter Lakes, below Tussum, near Serapeum. In the new edition he contends that the term "Yam Sûph" refers to the expanse of water now called the Red Sea, in opposition to Sayce's view which limits the term to the Gulf of Akabah, namely, the arm to the east of the Sinai peninsula. The author also identifies the present Ayûn Musa as the Elim of the exodus: this, like many other views advanced by him, is rendered eminently reasonable by his advocacy. The last chapter, entitled "Modern Events in Goshen," contains illuminating parallels from modern history to the events associated with the sojourn of Israel in Egypt, including an interesting reference to the attack on the Suez Canal during the recent war.

A Farmer's Handbook: A Manual for Students and Beginners. By R. C. Andrew. Pp. xvi+126+xliv plates. (London: G. Bell and Sons, Ltd., 1920.) 6*s.* net.

TEACHERS of agriculture would do well to take notice of this little book. It is written by a man who has had practical experience both of teaching and of farming and knows the difficulties that beset the student entering on a new subject. It is confined to the arable side of farming, and deals with the implements and processes necessary for ordinary root and cereal crops. Many common important processes are included which often miss the text-book writer's attention, such as methods of tying corn, sharpening a scythe, making a potato clamp, etc., and there is much information that is usually obtained only after painful and sometimes costly experience. The little book may be commended to the growing body of men and women interested in the cultivation of a patch of land who find themselves more and more called upon to do for themselves what was formerly done by the skilled odd man.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Biological Terminology.

DR. BATHER insists (NATURE, June 16, p. 489) that systematic zoology and botany are not wholly based on description, and gives some interesting interpretations of his own. Of course he is right—as right as if I had said that Africa is a land mass, and he had retorted that there were lakes in it. Driven by necessity, we all, even systematic zoologists and botanists, and even from infancy, practise inference and seek to make sure. We employ crucial testing when we desire to ascertain whether an explanation is true. We neglect it (*e.g.* in favour of rhetoric) when we wish merely to convince ourselves or others that it is true—as in the case of politicians, theologians, and those 262 biologists who propounded 262 explanations of sex and did not attempt to test even one. But all serious scientific interpretation is governed by very stringent rules: we must found our suppositions on verifiable facts; we must try to think of all alternative explanations of those facts; and, lastly, we must seek fresh and unlike groups of facts which shall eliminate, one after another, all the erroneous explanations. Then, and not until then, shall we have finished with mere guessing. As Uberweg puts it: "One single circumstance which admits of one explanation only is more decisive than a hundred others which agree in all points with one's own hypothesis, but are equally well explained on an opposite hypothesis."

Now, can Dr. Bather tell us of any modern sect of biologists which employs this method? It became fashionable among physicists and astronomers before Newton, and is still the very breath of their nostrils. Next it invaded chemistry—hence the rout of the alchemists. Then it captured physiology—hence the modern science. Darwin and some of his contemporaries tried to introduce it into biology. But with the passing of Darwin the impulse ceased. The new men proceeded, *unquestioned* (that is the damning point), to break every rule of scientific procedure. They coined multitudes of words that sounded tremendously scientific, but actually had no meanings in their mouths, *e.g.* germinal, blastogenic, plasmogenetic, somatic, and the like. They formulated hundreds of hypotheses, and argued about them strenuously, but—because of the vagueness of their principal terms (*e.g.* innate, acquired, inherit); because they rarely tested hypotheses and never as a body accepted a test; and because lack of crucial testing prevented the utilisation of oceans of unlike, but perfectly authentic and relevant, evidence that waited unexplored in a host of subsidiary sciences—their controversies were unending. Lastly, there happened the strangest event in the history of science. Groups of biologists, disgusted with the unceasing babble, declared that they were done with controversy, and founded the "exact" and "modern" schools. That is to say, each group, believing that a particular way of observing facts was especially modern and exact, proceeded to restrict its evidence to facts observed in that way. But, as we shall see presently, there is no especially accurate way of observing, and it is a fundamental axiom that all facts, no matter how observed, are equal before science. Again, if the area whence facts are derived be reduced, there is a corresponding reduction of evidence—of the power to discover crucial tests. Again, while controversy is unnecessary, there must be discussion, or the truth can never be established. There is a distinction between the two which implies a difference in temper. In controversy men try to belittle the facts and inferences of opponents; in discussion they candidly examine them with a view to ultimate agreement. Yet, again, "exact" and "modern" are rhetorical misnomers. This method of restricting evidence is very ancient. It has always fomented controversy, prevented discussion, and led, not to agreement, but only to the foundation and perpetuation of sects. Thus, Mohammedans have always used only Mohammedan evidence.

I am told that biologists think that I have wasted ink and paper on a subject—the method of science—which was thrashed out long ago. Certainly it has often been thrashed out; hence modern science. But never has it been thrashed out among biologists; hence the chaos in biology. As every biologist knows, his opponents, usually the majority, lack the right method; hence their incapacity to perceive the truth which to him is so plain. Anciently the scholastic thinkers founded their assumptions on unverified data and neglected to test them by fresh appeals to reality; hence the dark ages of Europe. Francis Bacon and his successors insisted that hypotheses must be both founded on, and tested by, verifiable data; hence modern thought and civilisation. But biology is still in the pre-Baconian stage. It is founded mainly on the unverified assumptions that some characters are more acquired, or innate, or inheritable than others, and, as I say, biologists rarely test their suppositions, and never as a body accept tests; hence the persistence, in great measure, of the dark ages in modern society. To-day no obscurantist dares to meddle with the established truths of astronomy, geology, or any interpretative science save biology. But he is still supreme in all that pertains to life. For example, he controls education, and, having rendered men unintelligent and trained them to unreason and passion, has recently drenched the world in blood. In England a million people, many of them innocent in every sense, are poisoned annually by means of easily preventable venereal disease, because ferocious, but ostensibly saintly, savages desire to punish sin. Yet man is a living being, and after all these years biologists should be able to tell us, with the full force of established truth, what may be achieved by education and how to achieve it. At present, notwithstanding the work of Lankester and others, biologists are impotent. However, it will not always be so. Sooner or later they are sure to fall into line with other scientific workers, and found one of the greatest and most potent of sciences.

I daresay biologists will think I am vapouring, for most of them are zoologists and botanists, and do not, almost as a point of honour, look outside their special sciences; and, while all biologists will agree that their opponents (usually, as I say, the majority) employ wrong methods of inquiry, none will believe that biologists as a class are ignorant or neglectful of the right method. Well, consider the following. Scores of similar instances may be found in literature. Once I read a book in which the author formulated suppositions of no very great importance, but which he, apparently using all the available evidence, tested carefully and established successfully. I may have been wrong in my opinion, and the author may have been superficial; but later I read a review of the

book by a very distinguished biologist. He controverted not a fact or an inference; all he had to say was: "The trail of the deductive thinker is over all." But how on earth can any supposition be established except by deduction? Crucial testing *is* deduction. All interpretative science has been created by it. "If my hypothesis be true and all others wrong, then this thing, and that, and that other must be true also. Let me see if it is so." Again, I once argued with another distinguished biologist. "But isn't the evidence true?" said I. "It may be," said he; "but it's not the sort of evidence we accept nowadays!" I found that his opinions corresponded with those of the writer of the following passage, another very distinguished biologist:—

"The recognition that only by experimental methods can we hope to place the study of zoology on a footing with the sciences of chemistry and physics is a comparatively new conception, and one that is by no means admitted as yet by all zoologists. I do not wish to disparage those studies that deal with the descriptive and the historical problems of biology. . . . It is undoubtedly true that many zoologists who have spent their lives in acquiring a broad knowledge of the facts of their science fail to make use of their information by testing the very problems that their work suggests. This is owing, no doubt, to their exclusive interest in the observational and descriptive sides of biology, but also in part, I think, to the fact that the experimental method has not been recognised by zoologists as the most important tool that scientists employ . . . the essence of the experimental method consists in requiring that every suggestion (or hypothesis) be put to the test of experiment before it is admitted to a scientific status. From this point of view the value of a hypothesis is to be judged, not by its plausibility, but by whether it meets the test of experiment. . . . It is sometimes said that Nature has already carried out innumerable and wonderful experiments. . . . Let us not be blinded by rhetorical questions of this kind." And so on, and so forth.

I wonder if anyone can tell us of a passage in any sort of literature which contains more misunderstanding than the one I have quoted. "Rhetorical" indeed! *Of course,* the essence of the experimental method is *not* that every suggestion shall be put to the test of experiment. Experiment is a mode of observing, not of thinking. It is used only when the desired facts cannot be directly observed, and only for the purpose of removing the conditions which obscure them. *Of course,* physics and chemistry are advanced and accurate, not because of difficulties in observing, but only because their workers have verified both their facts and their thinking, because they have accepted all tested suppositions readily, and because they have been in a position to measure and weigh accurately. They are experimental only because, from the nature of things, most of the desired facts were obscured and could not be revealed except by some device. Physicists and chemists would not be so silly as to experiment if they could observe at sight. As a fact, nearly all their established truths started with suppositions founded on patent facts, and were tested experimentally only because of the paucity of such evidence. There is nothing sacrosanct about a fact discovered experimentally, or about a hypothesis so tested. If you twist a dog's tail experimentally, the howl you elicit is not in the least more valuable intrinsically than the tail which you observe directly. You prove a man a thief just as surely by observing the spoons sticking out of his pockets as by turning them out. *Of course,* experiment is valuable; but we need not assign it wrong values. It enables us to penetrate below the surface. But a diving dress is not the only wear. There are things worth knowing on the surface—so many things, nearly all the facts of zoology, botany, and most other biological sciences, that if they be ignored, crucial testing is impossible. *Of course,* hypotheses, founded on or even confirmed by experiment, are, like all other untested hypotheses, mere guesses; whereas all tested hypotheses, whether proved experimentally or otherwise, are in a different category: for a real test is crucial; it not only confirms the truth, but also eliminates the untruth. If literature be examined I think it will be found that when anyone insists that all suppositions must be put to the test of experiment, he really asks that we shall ignore all evidence except that revealed by experiment, and all suppositions except those founded on experiment—that, in fact, we shall grant his facts the same status and his opinions the same immunity from criticism that other sectarians (*e.g.* Mohammedans) claim for their evidence and opinions. Compare Newton, who when he found that the moon's orbit (a thing which must be directly observed) did not, as then calculated, fit into his theory of gravitation, laid aside his supposition for many years, and published it only when a fresh inquiry demonstrated an error in the first calculation. Consider the glaring truism that "Variation is the sole cause of non-inheritance; apart from variations, like exactly begets like when parent and offspring develop under like conditions." No biologist will venture to dispute that truism. Is it necessary to test it experimentally? If it be true, what becomes of the Lamarckian and Neo-Darwinian suppositions, and much besides that biologists have unendingly "tested" experimentally and unendingly disputed about?

When such freakish, partisan stuff as I have quoted can be published and applauded, is it not evident that biology must remain a tumbling ground for whimsies unless its workers discuss and agree on its rules of procedure? The rules under which other interpretative sciences have been created—that language must be precise and significant, that all verifiable facts are equal before science, that all suppositions must be crucially tested before admittance to a scientific status, and that all fully tested suppositions must be candidly accepted—are so few and simple that were they rigorously applied, then, since the evidence is so abundant, it is certain that biology would soon rank among the greatest, best established, and most useful of sciences. It is generally thought that the multiplicity and diversity of biological phenomena, derived, as they are, or should be, from so many sciences, make the task of the inquirer peculiarly difficult. Actually the reverse is the case; for, when evidence is abundant and diverse, opportunities for testing are correspondingly frequent and established truth, rightly sought, should soon cover a wide area. Other sciences halt while evidence is painfully collected; biology halts because the methods of its students are such that they are unable to use the abundant evidence already available.

Dr. Bather says *à propos* of recapitulation: "At the moment when his letter was published some of us were discussing that very question at the Linnean Society, and Sir Archdall Reid, had he been present, would have seen that the issue was far from being the simple one that he imagines." As readers of NATURE know, I am very modest and retiring. Nevertheless, if Dr. Bather will indicate his difficulties I believe I can help him. The truth is, I have, on one hand, great faith in ordinary scientific procedure, and on the other, amid vast ignorance, a knowledge

of some facts which appear to have escaped the notice of biologists; for example, the truism I have mentioned, that, apart from variations, offspring tend to recapitulate the development of their parents.

G. ARCHDALL REID.

9 Victoria Road South, Southsea.

Solar Eclipse Results and the Principle of Relativity.

ON a recent occasion I read a paper before the Manchester Literary and Philosophical Society on the nature of dimensions, in which, admitting the possibility and even probability of space and time having secondary characteristics, like those suggested by Lorentz and Einstein, reasons were given for doubting whether the methods employed for finding them could be relied on, and experimental evidence, before it could be accepted, would have to be subjected to searching adverse criticism. Prof. Eddington's solar eclipse results were therefore submitted to a process essentially the reverse of his, which had for object not the confirmation of a theory, but the discovery of an empirical relation. During this process it soon became evident that the astigmatism of the cœlostat mirrors, which had given much trouble during the eclipse by distorting the star images, had also affected the field and altered the star positions. The stopping down of the objectives aggravated this evil in a double sense: first, the reduction of the star-image astigmatism makes it impossible to construct a picture of what might be called the field astigmatism of the mirrors; and, secondly, the smaller the diameter of the pencil of light rays for each star, the further apart would be the regions on the mirror from which these pencils were reflected. Therefore, if the various regions of the mirror had semi-independent tilts, the places of the stars on the plates would be affected by these tilts. If for some of the existing plates these pencils should be found to overlap, and if the star-image astigmatism is sufficiently marked, then these plates might still be used for the object for which they were taken.

Wishing, first of all, to redetermine the positions of the stars as they appeared before scale corrections had been applied in order to trace the wandering of the images, it was found that for the outermost stars 10 and 11 these negative corrections would amount to 0·45″. This in itself was a most disconcerting discovery, for the difference of displacement on which the eclipse conclusions were based is only 0·75″. It is, of course, quite impossible for the telescope tube to have altered sufficiently in four and a half minutes to produce this result, and a change of focus of the objective would have had no effect; therefore the mirror must have warped even during this short time. At Principe the passage of clouds would produce an irregular warping effect, and this would account for the unsatisfactory photographs obtained there. In order to form some idea about the nature of the field astigmatism it was now decided to estimate the tangential displacements of the stars, for these would not be influenced either by the scale corrections or by the radial displacements, but only by the mirror warpings. It was then found that stars 3, 4, and 6, which lie almost in a straight line between 5 and 10, had moved about 0·45″ across the connecting line of these outer stars. On averaging the uncorrected radial displacements it was found that a slight scale correction of about +0·0002″ had to be made, as was done by Prof. Eddington, in order to harmonise them with the Einstein estimates, the excuse in my case being that the mirror may have acquired a slight temporary concavity. If, however, there was a temporary convexity, necessitating a scale correction of, say, −0·0003″, the displacements would appear to conform to the empirical formula 1·09″−0·00022″. It will thus be seen that the use of cœlostat mirrors is not advisable where, as under eclipse conditions, rapid changes of temperature are unavoidable.

C. E. STROMEYER.

"Lancefield," West Didsbury, July 21.

MR. C. E. STROMEYER greatly exaggerates the possible effects of astigmatism of the cœlostat mirrors on the positions of the star images. He appears to consider that the pencils forming the different images are reflected from entirely different portions of the cœlostat surface. As a matter of fact, with the 4-in. lens the pencil producing the extreme star image was reflected from a portion of the mirror which had 85 per cent. of its area common to that producing the central pencil, and with the 13-in. lens (stopped down to 8 in.) the common portion was even greater.

That there was a slight astigmatism of the mirrors is not denied. Its presence was indicated by small differences in the scale and orientation constants of the plates determined in two different ways: from the right ascensions or declinations. These differences gave a measure of the amount of the astigmatism, and showed it to be very small and of very slight effect on the gravitational displacement. The question has been fully discussed by Prof. H. N. Russell (Monthly Notices, R.A.S., vol. lxxxi., No. 2, December, 1920), with the result that the conclusions deduced from the original reductions of the eclipse plates were fully substantiated and the Einstein displacement confirmed.

F. W. DYSON.

The Atomic Radius and the Ionisation Potential.

PROF. EVE's interesting contribution to NATURE of June 30, p. 552, on the relation between the ionisation potential and the atomic radius induces me to publish certain similar ideas of mine on the same subject to which I referred some time ago before the Royal Society in some remarks on Prof. Rankine's paper "On the Proximity of Atoms in Gaseous Molecules" (Proc. Roy. Soc., February, 1921). I did not publish the results, because I desired to wait for further data. These ideas may be stated as follows:—

According to the Rutherford-Bohr model of the atom, by the radius of the atom is meant the distance from the nucleus of the outermost electron, *i.e.* the electron the quantum vibrations of which cause the radiation of the arc lines of the atom. Sommerfeld has shown that in the normal (unexcited) state the orbit is characterised by the azimuthal quantum-number unity and the radial quantum-number zero. This orbit is circular, but to calculate its radius we must know what is the field of force exerted by the central nucleus and the remaining $(n-1)$ electrons upon the vibrating electron. This is at present an insoluble problem, but Mr. S. N. Basu (*Phil. Mag.*, November, 1920) has shown that we can at least arrive at a qualitative explanation of Rydberg's laws of spectral regularity by assuming the attracting system to be equivalent to a net central charge unity, with a doublet of strength L. On the bases of this theory, if a_x is the radius of the monoquantic orbit, it is easy to show that

$$\frac{e^2}{2a_x} = -\text{energy of the vibrating electron.}$$

$=h(1s)$ where $(1s)$ = convergence frequency of the principal series of the element in absolute measure.

$=eV_x$, V_x = ionisation potential in *e.s.* units.

For the H-atom we have, according to Bohr's theory,

$a_H = \frac{h^3}{4\pi^2 e^2 m}$ (a_H=radius of the electron in the normal state).

$$=0\cdot532 \times 10^{-8} \text{ cm.}$$

and

$\frac{e^2}{2a_H} = e(13\cdot54 \text{ volts})$. Therefore for an element x with an ionisation potential of V_x we have

$$a_x = \frac{(0\cdot532 \times 13\cdot56)}{V_x} \times 10^{-8} \text{ cm.}$$

Thus *the atomic radius varies inversely as the ionisation potential.*

The atomic radii calculated according to this formula are, in general, smaller than the atomic radii calculated either from crystal data (Bragg) or from the kinetic theory of gases (Rankine and others). They are shown in the appended table for the sake of comparison :—

Atomic Radius.

The values of V_x for copper, silver, and gold have been calculated from Hicks's value of the (1S) term for these elements. That for manganese has been similarly calculated from Mr. Catalan's value of (1S) for manganese (not yet published). For these data I wish here to record my indebtedness to Prof. Fowler and Mr. Catalan. The sources for the other values are quite well known.

MEGH NAD SAHA.

American and British Superannuation Systems.

I READ with great interest the article in NATURE of June 30 on the American and British superannuation systems. The selection of a satisfactory scheme of superannuation is a matter of great importance in the organisation of a public service. On the one hand, an age limit can be effectively enforced only when suitable provision is made for those who are forced to retire, and on the other the provision of a pension conditional on the completion of a full term of service is objectionable, because a public servant who retires before that period is completed is penalised by the loss of a portion of the consideration for which he has given his labour. The result is that although a man may feel that he would do better work in another sphere, and has an opportunity of doing so, he cannot bring himself to forgo the pension towards which he has already contributed some years of service.

The recent Committee of the British Science Guild on the Utilisation of Science in Public Departments considered this question, and came to the conclusion (Journ. Br. Sci. Gd., June, 1921, p. 37) that the best solution appeared to be to award at the end of every year's service a pension (or alternatively an endowment insurance) accruing at the age fixed for superannuation (or in the case of the insurance at that age or previous death), independently of whether the officer had remained in the service or not. The advantages accruing in respect of a single year's service would, of course, be comparatively small, but those for successive years would, when added together, furnish an adequate provision for the old age of officials who had served the full term, while they would be a welcome addition to the resources of those whose later careers had followed other directions.

It is essential that these benefits should be secured by public funds, and based on actuarial calculations at current rates of interest. The amounts now quoted by insurance companies are apparently calculated on pre-war rates, and are far too low.

This scheme could be adopted whether the basis of the superannuation were contributory or not.

July 19. JOHN W. EVANS.

MAY I point out, in connection with the note appended to my letter printed in NATURE of July 21, p. 651, that if only one mutual life assurance company were available the argument quoted in the leading article of June 30 would be answered, for that argument implied that dividends necessarily go to shareholders? The remark about expenses in the note leaves the point of paragraph (3) of my letter untouched, and the final sentence of the note makes me wonder whether the two-year-old American "Teachers' Insurance and Annuity Association" will grow up and prove itself to be more "philanthropic" than the selected assurance companies in England.

I am afraid that, quite unintentionally, my former letter must have seemed offensive to have justified your note to it. The hot, dry weather has been, and still is, trying to us all, *et tout comprendre c'est tout pardonner!* W. PALIN ELDERTON.

July 22.

A Novel Magneto-Optical Effect.

IN connection with the very interesting observations communicated by Dr. R. Whytlaw-Gray and Mr. J. B. Speakman (NATURE, July 14, p. 619), I should like to point out the close similarity of the phenomena which they have observed with those observed in the case of soap solutions (Proc. Roy Soc., A, 1921, vol. xcviii., p. 395; and Journ. Chem. Soc., 1920, vol. cxvii., p. 1506).

Gray and Speakman describe the formation of flexible strings or fibres in clouds of various metallic oxides, these fibres being made up of particles of colloidal dimensions which still retain their individuality. Miss Laing, in her study of gelatinisation, was led to the conclusion that such conjunction or orientation of colloidal particles forms the mechanism of gelatinisation. For instance, in a soap solution the individual colloidal particles are otherwise the same in the liquid sol as they are in the elastic jelly. In the letter referred to it is pointed out that the particles in a cloud of cadmium oxide have an exceptional tendency to form such strings, and this agrees with the striking behaviour of Svedberg's sols of the same substance in alcohol, which on standing gelatinise, but on slight shaking revert to the fluid condition, an alternation which can be indefinitely repeated.

Gray and Speakman's results are of special interest because they occur in a particularly simple system, and thus afford opportunity for studying the mechanism of this effect, which, if Miss Laing's hypothesis is correct, must account for gelatinisation, even in the most complicated systems. J. W. McBain.

University of Bristol, July 19.

Science and Civilisation.

Capt. B. J. Marden's letter in Nature of July 14 (p. 623) raises a question which must be exercising the minds of many of the readers of Nature to-day. That question is: How can scientific workers collectively obtain such control of the product of their work—new knowledge—as to secure that it shall be used for the development of a better order of society out of the existing chaos? Science—knowledge—alone can create this new order and save Europe from relapsing into barbarism. If this be accepted as a true statement of fact, we are led naturally to inquire: What are the best methods to pursue to secure that science shall be so applied?

The time is now ripe for scientific workers to set to work to devise a practicable scheme which will give to science its proper place in shaping the future destinies of the world. This is one of the chief purposes for which the National Union of Scientific Workers exists. Capt. Marden's idea seems to involve a sort of international Syndicalism applied to scientific workers and to scientific work. (Those readers who know about Syndicalism only from the daily Press will find a clear exposition of the Syndicalist position in Mr. Bertrand Russell's "Roads to Freedom," chap. iii., Geo. Allen and Unwin, 3*s*. 6*d*.) Such an organisation would offer no adequate security against the tyranny of a group over the rest of the community; and a dictatorship of scientific workers might be almost as great an evil as a dictatorship of miners, or of food producers, or of financiers. We should like to urge Capt. Marden and others who may have thought out schemes for the proper utilisation of science for the salvaging of what is worth preserving in our civilisation, and particularly those who have thought them out in the light of the large and growing volume of literature on the problem of the *rôle* of the producer (whether a producer of knowledge or of other essentials) in the future society, to publish their ideas in detail.

Bees and Scarlet-Runner Beans.

In Nature of August 12, 1920 (vol. cv., p. 742), a letter was published from me on the behaviour of bees visiting the flowers of the runner bean, *Phasiolus multiflorus*, to the effect that almost invariably the nectar was obtained from the flower by penetrating the calyx and corolla close to the position of the nectaries, the humble bees with their stronger mandibles biting through the sepals, while the honey bees took advantage of this pioneer work of their stronger relatives.

To my surprise, this year I find no such depredations made on the blossoms, but all the numerous humble bees are getting the nectar in a legitimate way, that apparently indicated by Nature, viz. by clinging to the more open left side of the flower and intruding the proboscis beside the pistil and stamens down to the nectar at the base of the petals. No honey bees have yet been seen on the flowers, but whether because of their scarcity or by reason of their being now unable to reach the honey is not clear.

As the jasmine flower is still bitten by the humble bees, it would appear that the hot and dry season has caused the change in the behaviour of the bees towards the bean flower, probably by hardening the calyx and making it more difficult to penetrate, while causing the bloom to be less in size and depth, so that the nectar can be more easily reached from a frontal approach. Harford J. Lowe.

Torquay.

A New Theorem on the Double Pendulum.

The following interesting relation is believed to be new:—

Let M and m be the masses of the bobs of a double pendulum, and let A and B be their respective amplitudes with suffixes 1 and 2 to denote the modes. Then

$$\frac{A_1A_2}{B_1B_2}=\frac{-m}{M}.$$

The negative sign merely indicates that in one mode the bobs are opposed, and it may therefore be ignored if the absolute values of the amplitudes are considered.

It is noteworthy that the product of the amplitude ratios is inversely as the mass ratio—that is, directly as the respective distances of the bobs from their centre of gravity. It is striking that the product of the amplitude ratios is independent of the lengths of the pendulums, *i.e.* independent of the relative position of the bobs and the point of support.

When the bobs are of equal mass it follows from the foregoing that the lower pendulum is divided by the vertical through the point of support into segments the ratio of which in one mode is the reciprocal of the ratio in the other mode, *i.e.* if one point of section be obverted or swung about the middle of the lower pendulum through 180°, the two bobs and the two points of section then form a harmonic range which has many well-known properties.

Ochreous Flint Artefacts from Sheringham.

I have recently paid another visit to Sheringham, and have again devoted my attention to the ferruginous "pan" which, for a distance of more than a quarter of a mile, is exposed in places in the base of the cliff forming Beeston Hill. From different areas of this "pan" I have taken fifteen more examples of the ochreous flints such as occur upon the foreshore exposed at low water. The specimens, as would have been clear to anyone examining the deposit intelligently, were, without question, *in situ*, and were embedded prior to the deposition of the great masses of glacial and other strata of which the cliff is composed. J. Reid Moir.

One House, Ipswich, July 22.

The Drought and Underground Water.

The present drought affords an excellent opportunity for studying natural underground drainage in limestone (including chalk) districts. In many streams part of the flow takes place underground, but the fact cannot readily be ascertained while a surface flow continues. The flow of small streams is now so much reduced that the whole stream may be swallowed in the limestone and may reappear lower down. It is to be hoped that geologists in limestone districts will seize this opportunity to make observations. Bernard Hobson.

The Application of Interference Methods to Astronomy.

By H. SPENCER JONES, Chief Assistant, The Royal Observatory, Greenwich.

THE recent measurement at the Mount Wilson Observatory, California, with the aid of an interferometer, of the angular diameter of the star Betelgeuse has attracted much attention, and has incidentally illustrated the advantages to be derived from the application of interference methods to astronomical measurement. In view of the striking success of this application, it is somewhat surprising that the possibilities of the method have been generally overlooked by astronomers, for the principles underlying the methods are by no means new, and their application to the determination of the angular diameters of the stars was indicated by Fizeau so long ago as 1868. It is of interest to recall the exact words used by Fizeau, the suggestion being thrown out by him incidentally in a report on the Bordin prize of the Académie des Sciences:—

"Il existe, pour la plupart des phénomènes d'interférence, tels que les franges d'Young, celles des miroirs de Fresnel, et celles qui donnent lieu à la scintillation d'après Arago, une relation remarquable et nécessaire entre la dimension des franges et celles de la source lumineuse; en sorte que les franges, d'une ténuité extrême, ne peuvent prendre naissance que lorsque la source lumineuse n'a plus que des dimensions angulaires presque insensible; d'où, pour le dire en passant, il est peut-être d'espérer qu'en s'appuyant sur ce principe et en formant, par exemple, au moyen de deux larges fentes très écartées, des franges d'interférence au foyer des grands instruments destinés à observer les étoiles, il deviendra possible d'obtenir quelques données nouvelles sur les diamètres angulaires de ces astres."

Stéphan was the first to attempt the determination of the angular diameters of stars in this way. He worked out an approximate theory, based upon elementary considerations, of the interference phenomena obtained in the focal plane of an objective when a uniformly illuminated circular disc, of small angular diameter α, is viewed through it, the objective being covered by an opaque screen in which are two parallel narrow rectangular apertures. The conclusion was arrived at that, in general, a series of parallel and equidistant interference fringes would be obtained, but that the fringes would disappear if the distance apart of the slits l satisfied the relationship $\alpha=\lambda/l$,[1] λ being the mean wave-length of the light. A determination of the distance apart of the slits for which the interference fringes disappeared is therefore sufficient to enable the angular diameter of the object to be deduced. The practical difficulty arises that in attempting to determine in this way the angular diameter of a star, the loss of light due to the restriction of the aperture to two narrow slits is so great that the fringes would in general be very faint. Stéphan removed this difficulty by showing that extended apertures could be used without serious error provided that they were equal and possessed two axes of symmetry at right angles to each other, one of these axes passing through the centres of the two apertures, and that their width was small compared with their distance apart.

With the 80-cm. Foucault refractor of the Marseilles Observatory, Stéphan, in 1874, examined Sirius and other stars. The fringes were obtained, but they did not vanish even with the maximum possible separation of the slits. The least diameter measurable by this method with this instrument was $0''.16$, but from the appearance of the fringes Stéphan was able to conclude that "les expériences citées ne prouvent pas seulement que le diamètre apparent des étoiles examinées est inférieur à $0''.16$, elles montrent encore que ce diamètre est une très faible fraction du nombre précédent."

The subject was taken up again by Michelson, who, in 1890, gave a more rigid theoretical discussion of the method than Stéphan had done. Three cases of interest were examined, and the principal results obtained may be summarised thus:—

(i) If the object is a circular disc of uniform brightness, of apparent angular diameter α, the series of interference fringes produced in the focal plane of the objective when the aperture is limited to two narrow rectangular and parallel slits will vanish when the distance apart of the slits l is given by $l=1{\cdot}22\lambda/\alpha$.

(ii) If the object is not of uniform brightness this relationship is modified. The precise modification for any given law of variation of brightness can be easily determined. If, for instance, the illumination falls off towards the limb according to the law of darkening observed for the sun, the relationship becomes $l=1{\cdot}33\lambda/\alpha$.

(iii) If the object is a double source, with an angular separation of the components of amount α, the fringes vanish for a distance apart of the slits given by $\frac{1}{2}\lambda/\alpha$, provided that the two components are of equal brightness, that their distance apart is large compared with their separate diameters, and that the length of the slits is perpendicular to the line joining the centres of the two sources.

The method has practical application in the measurement of the angular diameters of small bodies such as planetary satellites and asteroids, and more recently of the angular diameters of stars, and also in the measurement of the separations and position-angles of close double stars or spectroscopic binaries.

The angular diameters of small bodies such as satellites are usually measured with a filar micrometer. The measurement is possible only under conditions of the best atmospheric definition, and even then the probable error of observation is relatively large, since the width of the finest spider web is comparable with the linear dimensions of the image in the focal plane of the telescope. Using the interference method, it is found

[1] A rigid mathematical investigation replaces this by the relationship $\alpha=1{\cdot}22\,\lambda/l$.

that the fringes can be well observed even under conditions of poor atmospheric definition, when the use of a filar micrometer would be impossible. The method has the further advantage that as the distance apart of the slits is varied, the separation which causes the fringes to vanish can be very precisely determined, so that the error of observation is greatly reduced. With small, faint objects, on the other hand, the loss of light arising from the use of narrow slits is serious. At the Paris Observatory an attempt was made to determine by this method the angular diameter of the major satellites of Jupiter, but the light was not sufficient to render the fringes visible. Hamy, therefore, extended the theory to the case in which the slits are of a width which is comparable with their distance apart. If the slits are rectangular, of width a and distance between their centres l, the formula obtained by Michelson for the distance corresponding to the vanishing of the fringes must be replaced by

$$l = 1{\cdot}22\ \lambda/a\{1 + 0{\cdot}765\,(a/l)^2\}.$$

Michelson and Hamy used the method for the measurement of the angular diameters of the major satellites of Jupiter. Michelson, in 1891, observing with the 12-in. equatorial at the Lick Observatory, used adjustable narrow slits. Hamy, in 1899, used the large equatorial *coudé* of the Paris Observatory, and prepared a series of screens of such dimensions that their width was one-third of their distance apart ($a = \frac{1}{3}l$), the widths being calculated so that the angular diameters, α, deduced from the above formula decreased by 0″·1 with successive screens. The screens for which the fringes became least distinct were found, and by interpolation the angular diameters of the satellites were estimated to 0″·01. The angular diameters so obtained, reduced to a distance of five units for Jupiter, were as follows :—

	I.	II.	III.	IV.
Hamy	0″·98	0″·87	1″·28	1″·31
Michelson ...	1·02	0·94	1·37	1·31

The agreement between the two series is very much better than would be obtained with micrometer observations.

The method does not appear to have been further employed until the past year, when, at Michelson's suggestion, it was tried with the 100-in. Hooker telescope at Mount Wilson. In view of the advantages of the method, this seems somewhat surprising; possibly it is due to an exaggerated idea of the difficulty of the observation. Besides the application to satellites and asteroids, the method might be employed for the measurement of the oblateness of such bodies as Mercury, which have no satellites from a study of the motion of which the oblateness might be theoretically deduced, and for which micrometrical observations are not sufficiently accurate. It can easily be shown that by rotating the slits into different orientations the corresponding angular diameters are determined.

At Mount Wilson the method has been applied to the measurement of the angular diameters of stars. Theoretical considerations have indicated that the stars of largest angular diameter are to be sought amongst the giant red, or M-type, stars, such as Betelgeuse, Arcturus, etc., but that for no star is the diameter likely to exceed 0″·05, a quantity scarcely within reach even of the 100-in.

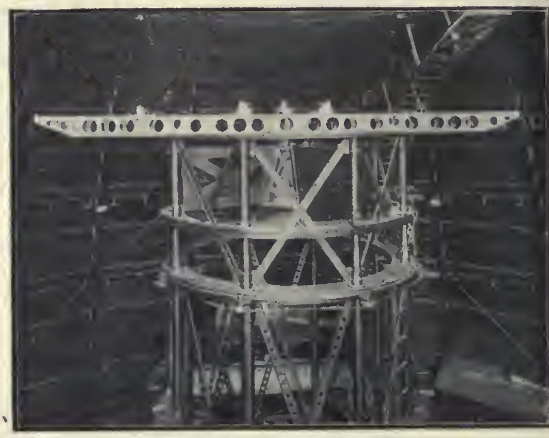

FIG. 1.—Stellar interferometer attached to end of tube of 100-in. telescope at the Mount Wilson Observatory.

reflector at Mount Wilson. Michelson, in 1890, had, however, indicated the possibility of employing the method in conjunction with an interferometer, thereby enabling the original separation of the two beams to be increased very considerably. The arrangement used at Mount Wilson is shown in Fig. 1, and diagrammatically in Fig. 2. A steel girder, LL, 20 ft. in length is fixed across the upper end of the tube of the 100-in. telescope. Two adjustable plane mirrors, AA,

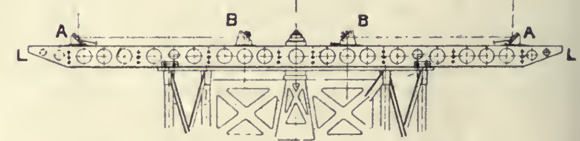

FIG. 2.—Plan and elevation of stellar interferometer.

reflect the light from a star along the girder to two other mirrors, BB, 4 ft. apart, which in turn reflect the light down the telescope tube to the mirror, the two pencils finally uniting, as shown in Fig. 3, and producing interference fringes in the focus of the eyepiece. To obtain the equality in the path of the two beams (which, for interference in white light to be observed, must be of an accuracy of 1/10,000 in.), an adjustable double wedge of glass is placed in the path of one of

the beams, compensated by a plane parallel plate in the other beam. The girder is capable of rotation, so as to test whether the fringes vanish in all position-angles, thus excluding the possibility of the vanishing being due to a double source. The observation calls for a high degree of experimental skill, as all who have used an interferometer will realise, and after shifting the mirrors it is a matter of considerable difficulty to find the fringes again.

With a base line of 20 ft. it should be possible to observe the disappearance of the fringes in the case of stars the angular diameters of which exceed about $0''.02$. When the telescope was pointed on Vega the fringes did not disappear even when the two adjustable mirrors were at their maximum separation, indicating that the angular diameter of Vega is less than this amount. In the case of Betelgeuse the fringes disappeared when the separation of the mirrors was 10 ft. Adopting as the mean wave-length of

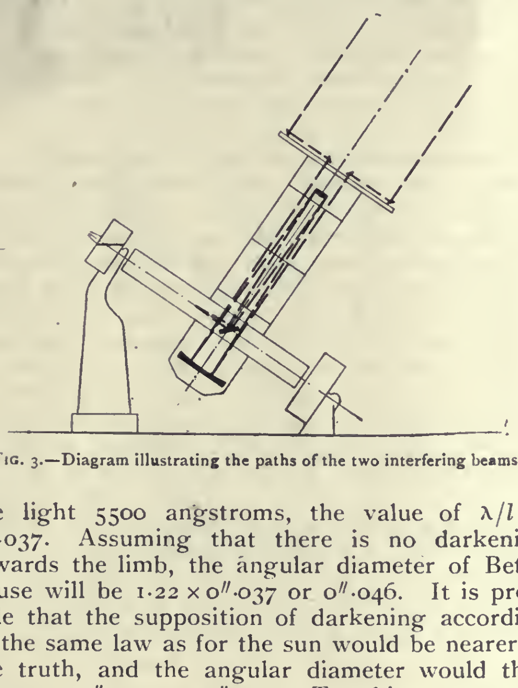

FIG. 3.—Diagram illustrating the paths of the two interfering beams.

the light 5500 angstroms, the value of λ/l is $0''.037$. Assuming that there is no darkening towards the limb, the angular diameter of Betelgeuse will be $1.22 \times 0''.037$ or $0''.046$. It is probable that the supposition of darkening according to the same law as for the sun would be nearer to the truth, and the angular diameter would then be $1.33 \times 0''.037$ or $0''.049$. To this extent the deduced angular diameter is uncertain. More recently the fringes were found to vanish in the case of Arcturus when the mirrors were 19 ft. apart, corresponding to an angular diameter of $0''.024$. This is almost the limiting angular diameter which can be measured with the present apparatus.

The number of stars the angular diameters of which exceed $0''.02$ is probably not very great; according to Eddington's estimate they are to be found amongst K-type stars of zero visual magnitude, or M-type stars of zero to third magnitude. The appearance of the fringes in the case of Vega with the maximum separation of the mirrors was so distinct, however, that it is considered that interference would be obtained with a base line of 100 ft. or more; if the mechanical difficulties can be overcome, the application of the method will no doubt be extended to base lines greater than 20 ft.

The determination of the angular diameters of stars is possible only with the aid of a very large instrument. For the measurement of the separations and position-angles of close double stars, the method can be employed with comparatively small instruments, and it is in this field that the method possesses the greatest possibilities. Its advantages as compared with the use of a filar micrometer are considerable. Adopting the late Lord Rayleigh's criterion for resolving power, a double star will appear just separated in a telescope if the central image of one component falls on the first diffraction ring of the other; since with a telescope of aperture d the distance between the central image and first diffraction ring is $1.22\lambda/d$, it follows that this is the smallest angular separation of the components of a double star for which the star will appear double. But with the interference method, as has already been stated, the fringes disappear provided that the distance apart of the slits is $\lambda/2\alpha$, α being the angular separation of the components, the fringes due to one star then falling exactly between those due to the other. The least separation which can be observed by this method, corresponding to a distance apart of the slits equal to the aperture, d, is therefore $\lambda/2d$, and it will be seen that the method increases the resolving power of a telescope in the ratio of about 2.44 to 1. Expressing d in inches, the normal angular limit of resolution is approximately $5''/d$; with the 100-in. telescope a separation of $0''.05$ should be just observable with normal methods of observation, the interference method reducing this to $0''.02$. That this increase in resolving power is actually obtained is proved by the observations of Capella at Mount Wilson. This star was known to be a spectroscopic binary, but visual methods had failed to separate the components, though it was established that their separation could not exceed $0''.06$; it therefore provided an interesting test object. The disappearance of the fringes was easily observed with the 100-in. telescope; the distance apart of the slits when this occurs determines the separation, and their orientation the position angle of the binary. Observations secured on six nights enabled an orbit to be computed. The observed distances and position-angles, together with the residuals from the values deduced from the computed orbit, are as follows:—

Date	Distance	Residual	Position-angle	Residual
	″	″	°	°
1919 Dec. 30	0.0418	0.00000	—	—
1920 Feb. 13	0.0458	−0.00003	5.0	+0.4
,, 14	0.0451	+0.00004	1.0	0.0
,, 15	0.0443	0.00000	356.4	−0.9
Mar. 15	0.0505	0.00000	242.0	−0.4
April 23	—	—	(not stated)	−0.2

These figures emphasise the remarkable accuracy of the method (the largest residual in distance is only four ten-thousandths of a second of arc!). It is stated that with care both angular separation and position-angle can be measured with an accuracy of about 1 per cent. This accuracy is much greater than is possible with a filar micrometer. The method possesses the further advantage that the percentage accuracy in both distance and position-angle does not decrease with decreasing separation; with the filar micrometer, on the other hand, the error of observation increases considerably with decreasing separation. For the successful use of the interference method good "seeing" is not essential, whereas for the observation of close double stars with a filar micrometer very good seeing is necessary. In explanation of this unexpected result it is suggested by Hale that "in bad seeing, when using the whole aperture of the objective, there is an integrated effect of the light-waves meeting in all possible phases, which tends to obliterate the details of the diffraction pattern of the star-image, but that when two light pencils are selected at opposite ends of a diameter the result is not an integration, but a mere displacement of the diffraction-pattern, sufficiently small for the eye to follow."

If the distance between the slits is greater than the value $l=\frac{1}{2}\lambda/\alpha$, which gives a unique position for which the fringes disappear, there will be four position-angles for the slits in which this occurs, these positions being symmetrical with reference to the line joining the two components, viz. $p\pm\theta$ and $p+\pi\pm\theta$, where p is the required position-angle. The most accurate method of observation is to adjust the distance apart of the slits so that θ is about 30° to 50°, and to measure the four positions in which the fringes vanish, so determining θ and p; if the separation of the slits is l, the value to use for the computation of the separation of the components of the binary is $l \cos\theta$, the separation therefore being $\lambda/2l\cos\theta$. If three different values of l are used and the corresponding values of θ are determined, the accuracy of the observation is increased. We have heretofore supposed that the components are equal in brightness and separated by a distance large compared with their diameters. If they are of unequal brightness the fringes do not completely disappear in any orientation of the slits, but instead the positions of minimum visibility (when the fringes of one star fall between those of the other) are observed. The variation in contrast is greater the more nearly equal the components are in brightness. The method is therefore suitable for the observation of close doubles which do not differ too greatly in brightness and are beyond the limit of resolution of, or observable only with difficulty and under the most favourable conditions with the telescope available, in conjunction with a filar micrometer. The time required for a single observation is longer, but this is more than compensated by the great increase in accuracy of the observation, by the possibility of observing under poor atmospheric conditions, and by the smaller number of observations required for the determination of an orbit. Prof. Hale expresses the hope that through a co-operative plan of observation, in which several observatories will take part, a large number of close binaries may be measured in this way.

An attempt is to be made at Mount Wilson to extend the method to the measurement of stars several minutes of arc apart. Until this is tried it cannot be asserted whether or not the difference of atmospheric disturbances along the optical paths of the two stars would prevent the fringes from being observed. If it proves feasible to observe them in this case it may become possible to measure the displacement of a star by the gravitational field of Jupiter, and thereby provide a further test of Einstein's theory, scarcely possible in any other manner. The method might then also be employed for the determination of stellar parallaxes and proper motions (which depend upon the differential displacements of adjacent stars) with a smaller probable error and in a shorter time than by existing methods. The further investigation of these possibilities of the method will be awaited with great interest.

The Paris Conference of the Museums Association.

FOR an association which, during the first thirty years of its existence, has confined its meetings to cities in the British Isles, the proposal to hold this year's conference in Paris seemed somewhat hazardous. Whatever objections may have presented themselves to some members, there can be no doubt that the experiment proved a greater success than any anticipated. During the week July 11–17 the seventy delegates from national, municipal, and semi-private museums, with their president, who, by good fortune, happened to be a man of such distinction as Sir Frederic Kenyon, were received in the most cordial manner by the heads of the State Museums of Art and of Science, by the Conseil Municipal and by the directors of its museums, and by the authorities of Les Invalides, the Bibliothèque Nationale, and similar institutions. Receptions at the Louvre, the Musée d'Histoire Naturelle, the Hôtel de Ville, and the club "Autour du Monde" enabled members to become personally acquainted with many French colleagues; and visits to the numerous and rich collections of Paris, Versailles, St. Germain, and Malmaison, under the guidance of distinguished authorities, with privileges accorded only to heads

of State among the lay public, enlarged the ideas of the British visitors almost beyond the limits of receptivity.

The inspiration and the actual knowledge of material and methods thus acquired cannot fail to benefit the museums and the municipalities which were wise enough to send their representatives across the Channel. On the other side of the account our French friends were good enough to admit some profit to themselves. The conservators of provincial museums in the recently formed French association were particularly pleased to see so many councillors of important cities, like Glasgow, Manchester, Hull, Carlisle, and Exeter, taking a keen interest in the proceedings and setting an example to their French brethren. Not only did the French museum officials observe with a pleased surprise that men of science and of art could co-operate to their mutual advantage, but the two camps in Paris were also (for the first time, one gathered) brought into friendly personal communication, so that the association may have begun the building of a new bridge across the Seine, from the Jardin des Plantes to the Louvre.

Among museums of interest to readers of NATURE, special mention should be made of the Musée National d'Histoire Naturelle, round the various departments of which the visitors were guided by Dr. Louis Mangin and members of his staff. It was pleasing to see how large had been the exchange of casts between this museum and our own Natural History Museum, and to recognise excellent specimens of British provenance. At the Musée Cluny Mr. De Montrémy explained the difficulties of arranging collections in a medieval mansion, and the curators noted how successfully he had overcome them. At the Louvre the recently introduced system of guide-lecturers attracted the attention of museum administrators. Demonstrations are given in French, English, Italian, and Spanish; there are from twelve to fourteen a week at the Louvre, and a few in the other art museums of the State. To restrict numbers and defray expenses, admission is by ticket, costing 3 francs each lecture. Some of the members listened to an admirable exposition of the work of David by Mr. Rey, who is the organiser of the lectures. The wonderful collections of prehistoric archæology at St. Germain, excellently displayed, and most kindly demonstrated to the party by Dr. Salomon Reinach, were among the greatest scientific treasures, and professional curators also appreciated the visit to the workshops.

To allow for the numerous outside attractions, the proceedings in the conference room were wisely limited. Dr. Hoyle's account of the system of registration employed at the National Museum of Wales provoked a lively discussion on the contrasted merits of books, loose-leaf ledgers, and card indexes. But here the chief feature was undoubtedly Sir Frederic Kenyon's presidential address, which, while dealing with the arrangement of museums of art and archæology from a general point of view, in reference to space and design, sketched out the lines on which, in the opinion of its director, the British Museum might most advantageously be modified. The congestion to which Sir Hercules Read has of late directed public attention has to be met. Experience shows that the growth of the collections cannot be overtaken by the mere addition of buildings. Recourse must be had to the storage in accessible cases of a large part of the collections, after the example set by the departments of natural history, of prints and drawings, of printed books, of manuscripts, and of coins. For the collection of Greek vases a division into three parts will be adopted, after the plan suggested by a former president of the association eighteen years ago—namely, a public gallery instructively and beautifully arranged; a series for study by amateurs; and a stored collection accessible to specialists. This method will save much room in many departments. More room, however, must be given to ethnography, since each distinct civilisation in time or space needs a distinct room for its display. A lecture room is required; the plans are prepared, and only await the funds to carry them out. A gallery should also be devoted to temporary exhibitions. The library ought to remain as the centre, with a ring of exhibition galleries round it, and an outer rectangle of storage and working rooms. Sir Frederic Kenyon concluded by enumerating some ways in which the British Museum could help local museums, and intimated that other ways would gladly be entered on if the curators of the local museums would make their needs known.

At the receptions in the Louvre and the Hôtel de Ville, as also at the association dinner, to which many of the French hosts were invited, Sir Frederic Kenyon emphasised the international importance of the gathering. The delegates from the national and municipal museums of Great Britain might, he said, be regarded as ambassadors preaching the gospel of peaceful civilisation and cementing the ties contracted by the two allied nations in war. This meeting might prove the first step towards an international association of museums, such as had long been in the minds of some members, and was again set up as an ideal by Dr. Loir, secretary of the Association of French Museums.

It was the enthusiasm with which Dr. Loir welcomed the suggestion of a Paris meeting, first publicly made at the Havre congress of the Association Française pour l'Avancement des Sciences (1914), that enabled the idea to be realised at last. It was the work of Prof. Roule and Drs. Bruyère and Lemoine, of the Musée d'Histoire Naturelle, that facilitated the execution of the plan. But the especial thanks of the association were accorded to its secretary, Dr. Tattersall, and to Mrs. Tattersall for their strenuous labours in seeing that the most audacious and the most far-reaching enterprise of the Museums Association was carried through most happily to a successful end.

Congress on the History of Medicine.

THE Second International Congress on the History of Medicine has just been held in Paris. The meetings were well attended, and the papers were of a high level of interest, and provoked some stimulating and fruitful discussions.

The members of the congress, who numbered several hundreds, were welcomed by the Chief Officer for the Organisation of Advanced Studies in France, representing the Minister of Public Instruction, who was at the last moment prevented from attending and delivering the inaugural address owing to an important Cabinet meeting. The Chief Officer emphasised the growing recognition of the importance of the study of the history of science, and especially of the history of biological science and medicine, as a method of enlarging the horizon both of the scientific worker and of the specialised scholar. The membership of the congress, which included the deans of all the great French medical schools, bore eloquent witness to this growing interest, and it was impressive to see not only that almost every country (except our own) has established university chairs in the subject, but also that excellent work is being done throughout Europe.

In Paris, as in Vienna, an extensive museum illustrating the history of medicine has been attached to the university. The interesting museum in Paris was formally opened at the medical faculty on the opening day of the congress.

It is possible to mention only a few of the papers that occupied a week's crowded programme. Both France and Belgium were strongly represented. Dr. Singer took the chair at the first session, when Prof. Jeanselme gave an account of diets in Byzantine hospitals and convents, deduced with great skill and ingenuity from contemporary non-medical documents. Prof. Jeanselme also gave an interesting paper drawing biological deductions from the records of medieval astrological lore. Prof. Ménétrier spoke of Eutrapel and sixteenth-century medicine.

M. Polain, of the Bibliothèque Nationale, pleaded for international co-operation in the bibliography of ancient medicine. In this matter substantial British contributions are available. The publication is eagerly awaited of the very complete and trustworthy "Bibliography of Medical Incunabula" up to the year 1485, compiled by the late Sir William Osler; while Mrs. Singer's "Catalogue of Early Scientific Manuscripts in the British Isles" provides a guide, available to students, though not yet all published, to the manuscript material of this country. Dr. Wickersheimer, the scholarly librarian of Strasbourg University, contributed two most illuminating papers on fourteenth-century medicine.

Dr. Tricot Royer, the president of the first congress, which met last year in Antwerp, gave an account of the hospitals of Antwerp from the year 1000 to the present day. The publication of his volume on this subject is eagerly awaited by scholars. Switzerland was represented by Prof. Cumston, of Geneva, and by Dr. Sigerist, the newly appointed lecturer in the history of medicine at Zurich, who gave a scholarly account of Conrad Heingarter and the astrological medicine of the fifteenth century. The professor of the history of medicine from the Jugo-Slav University of Prague spoke on Czech medicine in the fourteenth century, while another member from Prague gave an account of the rich store of material for medical history provided by the surviving graduation theses of the ancient university, extending over a period of many centuries.

From this country came an interesting paper on Harvey by Sir D'Arcy Power, and an account of pomanders by Mr. Thompson, of the Wellcome Museum. Dr. J. D. Rolleston joined in the discussions. Dr. Singer contributed a fourteenth-century text of the lost work of Guy de Chauliac on astrology, and Mrs. Singer gave an account of medieval plague tractates, and produced a Catalan hymn to St. Sebastian for preservation against the plague which she and Dr. Singer had discovered still in use in the Pyrenean village of Planès.

Lack of space prevents an account of the valuable papers from Armenian members of the congress, from Venice, Madrid, Lisbon, Copenhagen, Gorinchem and The Hague, Rio de Janeiro, and many other places.

Nor was the programme confined to papers and discussions. The courteous and indefatigable secretaries, Dr. Laignel-Lavastine and Dr. Fosseyeux, had organised a series of entertainments. The congress visited the Bibliothèque Nationale, St. Germain, the Louvre, and other museums, besides a number of the more ancient hospitals, and in each case the visitors had the privilege of an address from the heads of the institutions, who showed them the chief treasures. Baron Henri de Rothschild invited them to a performance of "Caducée," the remarkable medical play now enjoying great popularity in Paris, and the week was further enlivened by an admirable concert by an orchestra of medical men at the Cercle Volney, and by a reception given by the Municipality of Paris.

All members of the congress were struck by the number and high level of the papers contributed to the congress from both France and Belgium. It is indeed remarkable that these countries, the greatest sufferers from the war, have led the way in the establishment of the Congress on the History of Medicine, and have made so conspicuous a success of the first two meetings.

Dr. Singer gave a cordial invitation for the congress to meet next year at the Royal Society of Medicine in London, and the proposal was accepted with enthusiasm.

Will next year's congress see the establishment of a chair in this subject, and the opening of a museum attached to the University?

Notes.

THE Dean and Chapter of Westminster Abbey have given consent for a memorial tablet to the late Sir William Ramsay to be placed in Westminster Abbey as part of the Ramsay memorial. The tablet will be placed immediately below the tablet erected to the memory of Hooker, the botanist. The Ramsay Memorial Committee has commissioned Mr. Charles L. Hartwell to prepare the tablet with a portrait medallion of Sir William Ramsay, and Mr. Hartwell is now at work upon the tablet.

THE council of the Royal Photographic Society has opened a fund by means of which some permanent memorial may be set up at Lacock to W. H. Fox Talbot, upon whose researches the present-day practice of photography and of photo-engraving has been built up. As president of the society, Dr. G. H. Rodman appeals to all who are interested in photography to contribute to the fund. Donations, large or small, to the memorial will be gratefully accepted and acknowledged by Mr. W. L. F. Wastell, vice-president, Royal Photographic Society, 35 Russell Square, London, W.C.1.

IT is announced that a medal, to be known as the Meldola medal, will be presented annually by the Society of Maccabæans for the most noteworthy chemical work of the year carried out by a British subject who is not more than thirty years of age on completing the work. The award will be made by the council of the Institute of Chemistry acting with one member of the Society of Maccabæans, and power to vary the conditions of award is vested in the committee of the society and the council of the institute acting jointly. The object of instituting the medal is to recognise merit among the younger generation of chemists and to perpetuate the memory of Prof. Raphael Meldola, the distinguished chemist who served as president both of the society presenting the medal and of the Institute of Chemistry. It is hoped that the first presentation will be made at the annual general meeting of the Institute of Chemistry on March 1, 1922.

THE ever-increasing demands for information regarding the vegetable resources of South Africa, its plant poisons and plant pests, have given considerable stimulus to botanical research in that country. One result has been the establishment of the National Herbarium at Pretoria, which now includes all the more important private collections in the country. It has also been decided to issue from time to time a publication, which has been named *Bothalia* in honour of the first Union Premier and Minister of Agriculture, the late General Botha, consisting of contributions from the National Herbarium. It will include descriptions of new or little-known plants, cryptogamic and phanerogamic. Workers in systematic botany will find this publication of considerable interest and value, and intending subscribers should communicate with the Chief, Division of Botany, P.O. Box 994, Pretoria. The first part is now ready for issue, and may be obtained from the above address, price 7*s.* 6*d.* post free.

AT the meeting of the Royal Society of New South Wales held on June 1 Mr. R. T. Baker, curator and economic botanist of the Technological Museum, Sydney, was presented with the Mueller medal by the president, Mr. E. C. Andrews. This medal was awarded to Mr. Baker by the Australasian Association for the Advancement of Science at the annual congress held in Melbourne last January for his eminent services to botany, particularly in regard to the Eucalypts. In addition to his work on the Eucalypts, Mr. Baker is the author of more than 100 original papers on the Australian flora, as well as of several monographs, such as "The Cabinet Timbers of Australia" and his *magnum opus*, "The Hardwoods of Australia," recently published. On the art side he has published a work on "The Australian Flora in Applied Art," a book just now in request by art designers in England and America. Mr. Baker is also the author of several monographs in conjunction with Mr. H. G. Smith, assistant curator of the museum. These, like those mentioned above, are all written for the express purpose of developing the natural resources of Australia, and so lead to extended industrial enterprise for the good of the community. The two most important of this collaboration are "The Pines of Australia" and "The Eucalypts and their Essential Oils," both of which have opened new fields for the development of the valuable assets amongst Australia's natural resources. Although Australian botany was specially mentioned by the Australasian Association for the Advancement of Science, yet Mr. Baker's work has extended into other branches of technology covered by the various sections of the Sydney Technological Museum, which, besides being a museum, is a bureau of scientific information for the commercial world around it.

PROF. ARTHUR DENDY discusses in a recent number of the *Eugenics Review* the perennial problem of human evolution. He believes that "the evidence of progress in conformity with a great general principle or law of Nature is conclusive." But evolution tends to take place in a wave-like manner, and not in a continuous straight line. There is apt to be a setback after each climax. The reason for this is partly because available stores of energy become exhausted, and the race may not be plastic enough to adjust itself to new conditions or skilful enough to tap new supplies. The line of racial persistence is one of readjustment in the light of education. "The great principle of evolution . . . consists in sacrifice and re-birth at more or less frequent intervals—sacrifice of all those accretions which have become effete or developed beyond the limits of usefulness, and rebirth by making a fresh start with a clean sheet." Man has a unique capacity for this task, since he has the gift of foresight and the power of deliberate control. But this is as yet inadequately developed. It must be developed by education—an education which will on one hand seek to utilise the available results of scientific investigation—on which are based, as Huxley said, the rules of the life-and-death game—

and on the other will recognise that the lasting and satisfying values are those of truth, love, and beauty. The address is a notable one—a wise, scientific sermon by a leading biologist.

An account has been published (G. P. Putnam's Sons, Ltd.) of a meeting convened by Dr. Marie Stopes on May 31, in the Queen's Hall, London, for the discussion of constructive birth control. The chairman, the Rt. Hon. G. H. Roberts, M.P., spoke of the desirability of letting in daylight and securing trustworthy information; Dr. Jane L. Hawthorne urged the necessity of instructing those who sacrifice health and happiness through a rapid succession of childbirths; Dr. E. Killick Milard laid emphasis on the eugenic aspect of birth-control, not only in promoting the welfare of a sound family, but also in preventing the appearance of a bad one, and submitted that the experience of vast numbers of intelligent people who have used contraceptives has demonstrated that they are, on the whole, effective and harmless. Dr. Marie Stopes directed attention to the opening of the first birth control clinic in this country, and emphasised the far-reaching racial importance of positive, as well as negative, control. The advance of science, she said, has made it possible to present a material scientific basis with which to embody spiritual ideals. Instead of attempting the ascetic repression of mutual love, what should be aimed at is a culture of a love associated with a utilisation of available knowledge. "Married lovers should play the part of parents *only* when they can add individuals of value to the race." The interesting booklet contains a series of impressions of the meeting by the Rt. Hon. J. H. Clynes, M.P., and others. The whole forms a restrained, but urgent, presentation of the case for birth-control linked to a sound idea of marital relations.

Many interesting suggestions for further research into the methods of fish preservation are made by Mr. H. F. Taylor in a paper contained in the Proceedings of the American Fisheries Society for the year 1920. The paper deals with "The Principles Involved in the Preservation of Fish by Salt," and it contains the results of a series of experiments made by the author and others. The purest salt obtainable is recommended for ordinary methods of salting, for the impurities contained in crude products are of much significance. Calcium and magnesium salts retard penetration and harden and whiten the flesh, accentuating the "saltiness" of dried fish. Pure sodium chloride gives a "mild and sweet" cure, but the flesh is yellowish and soft. Dry salting leads to a more efficient and rapid preservation than does the use of a strong brine. Reddening of the flesh in dried salt fish is due either to a bacillus or to a spirochæte, which organisms can be traced to "solar," but not to mined, sea salt. "Rusting" in fatty fish is due to oxidation of fatty acids split off from the fats by enzyme action. Indeed, most of the defects of fish preserved in any way appear to be due to autolysis. Saltpetre, which is sometimes used as an accessory preservative, helps in the retention of a slight pinkiness of the flesh by forming a nitroso-compound with the hæmoglobin of the blood. These are some of the very important matters now being investigated in America—privately, it should be noted, for the author despairs of any helpful research by Government institutions, and looks to the fishing industry for adequate attention to problems of industrial fishery importance.

The problem of sex-determination in amphibia has for a long time been known to present special complexities. The evidence of R. Hertwig and others must be accepted as proving that external influences have an effect on the proportions of the sexes, and consequently, whatever be the true interpretation of this evidence, the simple rule of genetic predetermination cannot be held to apply without qualification to these animals. Intersexes have also often been observed, especially in the frog (see a recent summary by F. A. E. Crew, Proc. Roy. Phys. Soc. Edin., 1921, vol. xx., p. 236). M. Ch. Champy has lately made an interesting contribution to this subject (*Comptes rendus Ac. Sci.*, May 9, 1921). He found that by starving male newts (*Triton alpestris*) severely at the time when spermatogenesis should be active, the development of the secondary sexual characters is arrested, and the animal remains in a more or less neuter state, as in winter. In the following spring the testes of these animals are found to be replaced by bands of fatty tissue, and the secondary sexual characters do not reappear. Two such males, after being fed up in winter, were observed to undergo a peculiar transformation, assuming somewhat the coloration of the female. One was dissected on January 11, and showed only the fatty bands replacing the testes. The other was kept until April 8, and became entirely female in appearance. On dissection each fatty band was found to contain an ovary with young ovocytes, much as in newly metamorphosed females, together with an oviduct. The specimen in question had at the time of capture been an undoubted male, and reason is given for believing that it had fathered the fertile eggs of a female with which it had been paired in captivity before the treatment began.

In the Transactions of the Royal Society of Edinburgh (vol. lii., part iv., No. 30) Mr. J. M. Wordie publishes a paper on the soundings and deep-sea deposits of the Shackleton Expedition in the Weddell Sea. The soundings were 152 in number, and were made while the *Endurance* was a free agent and during her drift in the pack until she was crushed in October, 1915. This important series of soundings amplifies the only previous work in the Weddell Sea by the *Scotia* and the *Deutschland*, and was the principal scientific outcome of Shackleton's venture. No map accompanies the paper, but Mr. Wordie points out how the soundings remove all probability of Morrell's reported landfall or Ross's "strong appearance of land" in the north-west of the Weddell Sea. However, an island is still possible, even if unlikely. The continental shelf off Coats Land, discovered by the *Scotia*, has been proved to be narrow and irregular in contour. On the west of the Weddell Sea the *Endurance* took 103 soundings in depths under 275 fathoms, and proved the existence

of a series of stepped terraces with boundaries running north-east and south-west. These terraces run parallel with the eastern shore of the Weddell Sea, but at right angles to the presumed west coast. This terraced structure suggests that the Antarctic continental shelf is the result of earth-movements. The soundings of the *Endurance* were taken far west to touch the supposed deep in the Biscoe Sea, and they throw no further light on the problem of the connection of Antarctica with other southern continents. The rock-fragments obtained in the dredge, which on account of the movements of ice in the Weddell Sea probably all came from the east, tend to confirm the idea previously held that Coats Land belongs to the plateau type of Antarctica. Their evidence, however, is inconclusive.

THE Royal Geographical Society has recently issued two lists of place-names giving the spelling decided on by its permanent committee on geographical names for British official use. The first of these contains about 300 European names, and the second some 200 Asiatic names. Other lists are to follow. The aim has been to adopt so far as possible the native spelling, but in a number of cases the conventional form in use in this country has wisely been retained. The difficulty is to find a dividing line between the two systems. It is advocated, for instance, that the terminal "s" should be dropped in Marseilles, but retained in Lyons. Norwegian names beginning with a "K," like Kristiania, are spelt with a "Ch" in this list, for no apparent reason except usage. On the other hand, Gothenburg, the anglified version of Göteborg, is discarded, and Helsingör is given in place of Elsinore. It is not clear why Arkhangel should be spelt with "c" instead of "k"; the latter may not be the more usual practice, but has the advantage of expressing with least chance of ambiguity the sound of the Russian letter. Similarly Harbin, the form advocated in the list, gives the sound less truly than Kharbin. According to the Royal Geographical Society's own system of transliteration (*Geographical Journal*, January, 1921), the sound is equivalent to "kh." The correct transliteration is used in Sakhalin. It may be correct, but it will prove difficult in usage, to substitute such forms as Bosporus or Bukhara for the more usual Bosphorus or Bokhara.

THE Geological Survey has just issued the latest volume of its Special Reports on the Mineral Resources of Great Britain, dealing with rock-salt and brine, by Dr. R. L. Sherlock. The report is clearly written and very complete, reference being made to many even of the smaller brine springs existing in the country. It must be borne in mind that salt is one of the most important minerals produced in Britain, and that it forms the basis of an extremely important section of our heavy chemical trade; on this account information as to the occurrence and distribution of salt is of the greatest importance, and the Survey has done a valuable piece of work in collecting the information which has here been brought together.

DR. H. S. WASHINGTON contributes a paper of general interest on "The Chemistry of the Earth's Crust" to the Journal of the Franklin Institute, vol. cxc., p. 757, December, 1920, in which he correlates the regions of mass-defect and mass-excess, as shown by gravity-observations, with what is known of the chemical composition of the underlying rocks throughout the globe. He uses the analyses collected in the monumental Professional Paper 99 of the U.S. Geological Survey, and he finds that the rock-densities calculated from these analyses correspond well with the theory of isostasy. There is "a complete harmony between average specific gravity and average elevation everywhere," the rocks being less dense under the areas of higher land. In *Science* for March 4 C. K. Leith discusses the nature of the movements by rock-fracture or rock-flowage that occur in lower regions of the crust, and concludes that these are much like those that take place in the zone accessible to observation. Hence we need not postulate any single zone of flowage, such as Barrell's asthenosphere, and we are led towards "the Chamberlin conception of a heterogeneous structural behaviour of the earth."

DIURNAL variation in wind velocity and direction at different heights is dealt with by Mr. J. Durward in Professional Notes No. 15, published by the Meteorological Office. An attempt is made to discuss the results of pilot-balloon ascents made on the British Front in France at intervals of four hours. It is shown that winds up to a height of 3000 ft. have a minimum velocity at about noon, and the higher one goes the later does this minimum occur. At 4000 to 6000 ft. observations are generally insufficient, but there is evidence that west winds decrease by day and east winds increase. In general, a decrease in velocity is accompanied by a backing which may amount to as much as 20°. Results obtained on the same subject from pilot-balloons in Italy and in Batavia are referred to, and are said to be in close agreement.

CLOUDINESS in the United States is the subject of an article in the *Geographical Review* for April–June, 1920, by Prof. R. de C. Ward, of Harvard University. As a climatic element the amount of cloudiness is recorded by eye on a scale 0 to 10, and from observations made two or three times a day the mean annual and mean monthly amounts are calculated. In addition to this information the average number of clear, partly cloudy, and cloudy days in each month should be given. Maps of monthly and annual cloudiness for the United States have been available for the last thirty years or more, but the new maps drawn by the author have the advantage of more complete data collected and supplied by the Weather Bureau of the United States. In all, 190 stations are employed, and of these 65 had more than forty years of observations. The mean annual maps show that there are two districts of maximum cloudiness, both more than 60 per cent., one lying over most of the Great Lakes region and extending northward over the St. Lawrence Valley and northern New England, and the other on the extreme north-western Pacific coast. Both these

regions are said to be under marked cyclonic control. The northern States are more cloudy than the southern, and the Pacific coast as a whole is less cloudy than the Atlantic. July and August are the least cloudy months, whilst in the southern States the minimum cloudiness is in autumn. In Florida the cloudiest season occurs during the summer months.

THE report of the National Physical Laboratory for 1920 (the first year of the directorship of Sir J. E. Petavel) records an unusually large number of staff changes. Sir A. Schuster has become chairman of the executive committee; Mr. F. E. Smith has left to become Director of Research at the Admiralty; and Messrs. C. C. Paterson, A. Campbell, A. Kinnes, B. P. Dudding, E. A. Coad-Pryor, and Dr. N. Campbell have resigned, and some of these posts have not been filled. Mr. R. V. Southwell has been appointed superintendent of the aerodynamics department. The fees for tests have been increased, and the number of instruments sent for test has decreased as compared with 1913, notably in the case of optical and electrical instruments. A large amount of work has been done for industrial research associations and for Government Departments, but in future Admiralty work will be independent of the Laboratory. The programme of work for the present year includes the measurement of physical constants required in industry and in the medical profession, the improvement of the tests for photographic lenses, the study of the characteristics of three-electrode valves for wireless telegraphy, the manufacture of length standards of high accuracy, investigations on lubrication, tests of models of aeroplanes with air-screws running, light alloys research, and investigation of the interaction of ships.

THE Bureau of Standards, Washington, has issued a pamphlet on "The Spectrophotoelectrical Sensitivity of Proustite," by W. W. Coblentz, which is now ready for distribution, and may be obtained by anyone interested by addressing his request to the Bureau. This investigation is a continuation of previous work on various substances. At 20° C. the spectrophotoelectrical sensitivity curve of proustite has a wide maximum in the ultra-violet, with a weak, ill-defined band at 0·6μ. By cooling with liquid air the intrinsic sensitiveness is greatly increased, and there is a very large development of this band, which now shows a maximum at 0·578μ.

Our Astronomical Column.

THE AUGUST METEORS.—Mr. W. F. Denning writes:—"This annual shower returns to a maximum on about August 11, and the circumstances are rather favourable this year, the moon being near her first quarter and setting at 11h. 19m. G.M.T. There is no reason to expect an unusually abundant display, but it will be sure to provide an interesting shower of bright, streaking meteors. The larger objects should be carefully recorded, so that their real paths may be computed. The position of the radiant point and its change of place ought to be determined on each night when the atmosphere is clear enough for the purpose, for the shower is already fairly rich at the end of July, and is well maintained until the middle of August. This date, however, does not limit its duration, for occasional meteors are seen towards the end of the month. The morning hours are usually best, for the radiant is at a greater altitude after midnight than at an earlier period. Though this system of meteors has been sedulously observed during a great number of years, there is still much to be learnt concerning its annual variations, date of maximum, changes in the position and character of the radiant point, and in the relative strength of the numerous contemporary showers which are visible."

SEARCH FOR METEORS FROM THE PONS-WINNECKE RADIANT.—Prof. Barnard reports that he watched for meteors all night on June 24, 25, 26, and 27; although the search was fruitless it has considerable negative value as showing that the dense part of the meteor swarm did not intersect the orbit of the earth, so that it would appear probable that the shower of June, 1916, will remain the sole example of a shower from the Pons-Winnecke radiant.

Mr. R. G. Chandra, of Jessore, India, also reports a fruitless search for meteors on the night of June 25. He states that Prof. Ray, of Bolpore, saw two meteors radiating from the neighbourhood of θ Boötis.

Prof. Barnard mentions a telephonic report of a shower lasting ten minutes on the night of June 27. No further particulars were available.

STATISTICS OF PROPER MOTIONS.—No. 30 of the Publications of the Astronomical Laboratory at Groningen, by Prof. J. C. Kapteyn and Dr. P. J. Van Rhijn, is a continuation of the valuable studies in stellar statistics that have appeared in this series. It commences with a *résumé* of recent catalogues and other sources of our knowledge of proper motions, such as Mr. Innes's researches with the blink microscope. The question of the effective area of the sky covered in each research is considered—that is, if a catalogue is not exhaustive down to some assigned magnitude, it is considered to be exhaustive for a smaller area of the sky, determined by the number of stars contained in the catalogue.

One of the most interesting questions dealt with is the number of stars in the whole sky with motion between certain limits. The following table has been formed from data in Tables 6 and 7 of the book. For these large proper motions the distribution is shown to be independent of galactic latitude.

Limits of Proper Motion.

No. of stars in whole sky.	0·2″	0·3″	0·4″	0·5″	0·6″	0·7″	0·8″	0·9″	1·00″	1·50″	2·00″
Mag. 6	169	71	30	26	16	7	5	3	14	1	5
7	304	120	56	61	40	23	12	6	13	3	3
8	520	216	76	124	36	21	21	11	18	6	12
9	1125	410	103	38	47	25	34	13	51	21	9
10	1425	261	166	133	48	29	24	10	33	10	19
11	1770	342	200	135	63	117	45	36	90	9	0
12	1770	450	450	68	45	23	23	90	113	45	0
13	1620	690	400	225	135	23	113	45	23	23	28
14	1490	800	350	158	68	113	45	0	0	0	0

The 169 in the first line means that there are 169 stars in the whole sky with annual proper motion between 0·2″ and 0·3″ and magnitude between 6·0 and 6·9. Similarly in other cases. The figures for the faint stars are rough, since they are deduced from the examination of very limited areas.

The Universities and Technological Education.[1]

By PROF. A. SMITHELLS, F.R.S.

NEARLY three centuries ago Robert Boyle came to Oxford aglow with zeal for the pursuit of chemistry, a study which he was the first to establish as a science and to endow with the title of a philosophy. His work, it appears, aroused bitter animosity; he was attacked in the University pulpit for his theories and their corrupting influence; above all, indignation was felt that he, a gentleman by birth and position, should concern himself with low mechanical arts.[2]

If times had not greatly changed, the prospect of those coming here to-day to proclaim the University rights, not of pure science, but of technology, would indeed be cheerless. But times have greatly changed, and whilst, as the centuries have passed, the best of the ancient ideals that dominate this illustrious seat of learning have become more precious and inviolate, and whilst the chief glory of the University still lies, I suppose, in the realm of ancient studies, there has been so wide an expansion of intellectual sympathy that to-day natural science is in brilliant display, and technology itself is not only condoned, but in a measure also practised here.

It is no part of my purpose to urge upon Oxford an extension of this latest province of her work. It would be an impertinence, even if I felt eager, as I do not, to suggest it. But I hope it will not be an impertinence to make into something of a text the historical facts just recalled. I have always thought that our difficulties with technology have arisen chiefly from the belated and stinted cultivation of natural science in the ancient universities. For it is they that have to so large a degree given the law intellectual and set the currents of our education. If natural science as it arose had been gathered to the older studies and had flowed in its natural courses, the mechanical arts and those who follow them would surely have been brought long since into a very different relation with the academic world.

Those arts which are first in importance to hungry, naked, and pedestrian man were the last which man learned to imbue with rationality. The succeeding arts, which regulate communal life, gave birth to professions that soon became learned; the economy and safety of communal life gave leisure for the disport of fancy; and so it happened that when the range and achievements of man's intellect in the pursuits that relate to human intercourse and to the imagination had already reached such magnificence as to send illumination down the ages, the science that intellectualises the mechanical arts was only just emerging from the close concealment of its material garb. The early promise soon was blighted, and natural knowledge languished through the Middle Ages, leaving industry to make its progress in the light of art, but in the gloom of empiricism.

When at last science took on rapid growth, when the stir of invention quickened the pace of humanity and we entered upon the riot of the industrial age, there ensued a period lasting until now when industry has been struggling, consciously and unconsciously, for its intellectual rights, lacking most grievously the sympathy, the prevision, and the leadership that should have been forthcoming from the established centres of educational influence, the universities. And so we find ourselves in a land that has been forced to provide for itself as it could its bread-and-butter studies, its rations of useful knowledge dealt out to the toiler when his day's work is done, its technical schools, commercial academies, colleges of science, and I know not what else, standing outside and in the shade—improper still, I think, in many minds to what is education proper. We are not to blame those who have been busy in this work. "Necessity has no law, and expedience is often one form of necessity. It is no principle with sensible men of whatever cast of opinion to do always what is abstractedly best. Where no direct duty forbids we may be obliged to do, as being best under circumstances, what we murmur and rise against as we do it. We see that to attempt more is to effect less; that we must accept so much or gain nothing; and so perforce we reconcile ourselves to what we would have far otherwise if we could . . . it may be the least of evils . . . it may be professedly a temporary arrangement; it may be under a process of improvement; its disadvantages may be neutralised by the persons by whom or the provisions under which it is administered."

But we live in a time when we are forced as never before to consider our ways, to look beneath the surface of things, and to take thought for the future. It is a time when we must go back to principles and consider what, in Newman's words that I have just quoted, is "abstractedly best," a time when we may be excused for aggressiveness in asserting the fundamental principles of our faith.

Speaking in terms of our subject to-day, we may say that we find ourselves a people far spent by the cost of victory over a nation of technologists, a nation which had carried to the highest point the training of its people in applying exact knowledge to the mechanical arts of both peace and war, the knowledge that enabled it under stress to make gun-cotton from wood and air, to conserve its fats for food by making glycerine from starch, to fire a shell seventy-five miles, and to do a great many other marvellous things in the mastery of matter. I have not heard of any direction in which our late enemies could be charged with faults attributable to a neglect of technology. On the other hand, there is abounding evidence that without it they would have been defeated in a year. The tale of the forced march of our own technology in this war of chemists and engineers has not yet been fully told, and perhaps its triumphs are only dimly understood.

In the face of all this it would be excusable perhaps to make this the occasion to preach the urgency of technology. But that is not my intention; I am far more anxious to raise my voice against its unbridled pursuit, to direct attention to the restraints under which it should be fostered, and to plead for what seems indispensable to its worth.

Whatever may have been the ultimate source of German decadence, it has proceeded step by step with changes of outlook, of aim, and of organisation in education that were of melancholy significance to those who had any knowledge of the Germany of old. The reproach was not in their becoming a race of technologists, but in their education from beginning to end yielding to the domination of a spirit which set above all else the worship of power and material efficiency. Surely the supreme educational lesson of the war is that we teachers should stand shoulder to shoulder against all the forces that tend to the vitiation of the atmosphere of education and to the desecration of our temples of learning.

[1] From a paper read before the Congress of the Universities of the Empire at Oxford on July 6.

[2] Prof. H. B. Dixon, Address to Section B, British Association Reports, 1894 (Oxford), p. 596.

Unaltered as is my eagerness for the promotion of technological studies and undiminished my belief in their university rights, I can therefore, and do at the present time, listen at least with patience to alarmist voices more than hinting at the elimination of technologies from our universities. It is more grateful to the ears than some other prescriptions coming from advisers who would act on the precept that it is lawful to learn from the enemy, but would, it seems, have us learn just the wrong thing.

But we must be careful not to be thrown off our balance by a laudable emotion. It is perfectly certain that our national circumstances require, and will require in an increasing degree, the application of the highest knowledge to the industrial arts. An increasing proportion of those endowed by Nature with the best brains and the strongest elements of character will be absorbed by industry, simply because the maintenance of industry is a condition of existence, and its maintenance becomes more and more exacting of both mind and character.

The tendency of those who are so susceptible to anything that seems to threaten a depreciation of university life to say, "Let industry have the brains it wants, get them trained how it wants, and where it chooses—*anywhere but here*," seems to me a fatal closing of the eyes to what is written in blood on the pages of recent history.

Not less wrong, in my opinion, are those who still maintain that the universities have done their whole duty when they have provided the unspecialised studies that are fundamental to industrial science. We know, indeed, that these are all-important, and that men well trained in them, if properly used, will learn elsewhere in the end effectively to apply them. But that there exist ranges of special knowledge, essentially high science, lying between the abstract sciences and the mechanical arts, and that a training in this knowledge may be organised to great advantage in teaching institutions, will not be disputed by anyone who has regarded the evidence at hand. Certain it is that these so-called technologies will be taught somewhere, just as the specialised high studies of theology, law, and medicine are taught, and where they are taught well, there will they be sought. They will be sought now as never before, and what appears to be the matter most needing consideration in our discussion to-day, the point on which I wish to focus attention, is this: that unless the universities collectively embody enough high technology to meet adequately the prospective demand, we shall inevitably cast a large section of our best industrial manhood into institutions wholly devoted to one type of studies and dominated by aims which, however worthy, are directed to the object of immediate material utility.

I cannot believe that any thoughtful Englishman can now regard such a prospect with equanimity. He has surely realised too well the functions of a true university, and what we must exact from it for the education of our race: that it must be, above all, a centre of life in which we secure the influences that will regard and tend the idealism of youth, that will bring into good fellowship and sympathy young men coming from all quarters, cherishing every kind of healthy interest and going out into the world to every kind of legitimate pursuit. It must be a community where traditions of honour and high aims are created and impressed, and where no study is at home that is not fraught with a continually disinterested exercise of the mind.

"It is pledged to admit," says Newman, "without fear, without prejudice, without compromise, all comers, if they come in the name of Truth; to adjust views, and experiences, and habits of mind the most independent and dissimilar; and to give full play to thought and erudition in their most original forms, in their most intense expressions, and in their most ample circuit. Thus to draw many things into one is its special function."

It must be, in short, the place that Milton conceived as giving the "compleat and generous education that fits a man to perform justly, skilfully, and magnanimously all the offices both private and publick of Peace and War."

It is in such an environment surely that we must educate as many as we can of those who are to be the guiding spirits of the working world.

It has, I believe, seemed to many of us here, and certainly to some in the country itself, that the technological universities of Germany, the much-vaunted "*Technische Hochschulen*," have, in the field of education, been strikingly symbolic of a change of spirit in that nation. True it is that they have not usurped the very name of "university," but they made pretensions and acquired prestige and powers that in effect gave them an equal place, or even a prior one, in the esteem of their country. The German, it is true, has never abandoned his formal homage to the older university ideal, just as he has maintained in external form, over much of his educational system, the discipline of what are called "humanities." We have found the modern German still in a way informed in things intellectual, moral, and æsthetic, but we have felt that this equipment was becoming more and more a conventional outer garment, according less and less with the spirit it enveloped.

Nothing has happened that can rightly lead the Germans to relax their cultivation of technology, but among the signs of their regeneration we shall surely look for the return of a true allegiance to their older ideals of universities and all they must stand for in the scheme of a truer civilisation. They must acknowledge that there is something in university life transcending in importance the achievement of efficiency, and that the first care of the nation should be to see that its education proceeds where influences prevail that will touch the spirit of youth to right ambitions and ideals of life. Among the excesses of regimentation the Germans have, I think, good cause to reconsider their educational plan of isolating seminaries of technology.

If thus, in the light of recent history, I am brought to plead more earnestly than ever for the ranging of this set of studies for their own sake within the university, it is in no spirit of condescension or without a strong conviction that they have much to give as well as to gain. It has been my own fortune to live in a university which, perhaps more than any other, has made ventures in the domain of technology and has sought to bring into an articulated and harmonious whole, without preference or priority, without caste social or intellectual, on equal terms and with equal rights, the studies, teachers, and students concerned with both professional and industrial occupations. I do not know that there is one among our teachers who would not acknowledge advantage from this association and bespeak from it, when rightly achieved, a broadening rather than a narrowing influence on the best elements of university life.

I hope I am not insensible to the safeguards that must be observed. A tendency to extravagance lies in every new movement, and in relation to technology it is most important that there should be restraint of ill-considered plans. These safeguards I endeavoured to outline when speaking on this theme at the congress nine years ago. It is perhaps permissible again to urge that the universities should observe a due proportion and economy by differentiation in their technologies according to the natural homes of these, that they should study co-operation

in policy and encourage interchange of students. More important still as an actual need of the day seems to be this: that universities which associate themselves with technological institutions of originally independent growth shall bring the studies, teachers, and students effectively into the precincts and life of the university. Equally important does it seem that this should be done so far, and only so far, as these studies, teachers, and students can be rightly regarded as conforming to the standards of a university. It is to be feared that there lie here practical problems of grave difficulty, and that we may be entering upon a troubled time. The difficulties for the universities lie mainly in the suspicion, which they so easily incur, of possessing all those failings that are apt to beset aristocracies, and when they are prescribing restrictions in the light of experience and with a disinterested desire for the common good, they may easily enough be regarded as acting merely in a disdainful spirit of exclusiveness. Another danger, of course, lies in an eager spirit of accommodation, a disposition to please the multitude, and a love of peace, amid which essentials may be sacrificed to gain the mere semblance of success.

In the restlessness of our present world it is difficult to gauge the currents of opinion that will mould or remould the institutions of our country. But so far as education is concerned it seems clear that, if we are to accept their spokesmen, the rank and file of the teeming world of labour have set their heart in something like clear purpose to the ends that shall be sought. They will not have it that their new and increased education shall be permeated and dominated by a sordid or material aim. They begin to suspect the agencies that make their chief promise a cleverer performance of the daily task or the earning of a larger wage. In their revulsion from such an object they threaten to repudiate what in truth in its proper place, among other things, will lighten and enlighten their labours.

There is no sign of the times that to me seems more hopeful, for I see in it the promise of an end to the far-reaching and incalculable mischief that has come of a false distinction between useful and useless knowledge. But there are opposing forces to contend with.

It seems to me that there is no service of universities more needed now than to exhibit in the centres of highest education, which can so easily lead the way, the true intellectual nurture of industrial life—the embodiment of technology in full and fruitful fellowship and interplay with accepted liberal studies.

New Apparatus for Showing the Tracks of α-, β-, and X-rays.

It will be remembered that Mr. C. T. R. Wilson described his original cloud expansion apparatus as used for showing the tracks of α- and β-rays and of X-rays before the Royal Society in April, 1911, and at that time the Cambridge Scientific Instrument Co., Ltd. (now the Cambridge and Paul Instrument Co., Ltd.), took up the manufacture of this apparatus. The manufacture of apparatus of this class was, however, entirely stopped by the war.

Lately Mr. Takeo Shimizu, of Japan, working at the Cavendish Laboratory, Cambridge, has considerably modified Mr. Wilson's original apparatus, and the Cambridge and Paul Instrument Co., Ltd., is now putting the improved design upon the market. In Mr. Wilson's original apparatus only a single expansion was obtained. It was thought to be necessary to give a comparatively rapid expansion in the working chamber, and this was obtained by connecting the space under the moving piston to another space which was previously evacuated. The moving piston was, in consequence, suddenly sucked down against a rubber stop. Mr. Shimizu has found that the sudden expansion is not necessary, and has, therefore, arranged for a reciprocating piston, and he obtains cloud tracks of the rays at each expansion, which may be timed to occur at rates from about 50 to 200 per minute. The instrument thus designed is extremely simple, but there are several important points to which attention must be given for successful operation.

The apparatus is shown in Fig. 1. The crank (not seen in the illustration), which is driven either from the hand-wheel B or by means of a small motor, drives an upright connecting rod, which in turn drives a horizontal connecting rod D. The far end of D slides in a sleeve E, which is free to rock in the piece F. The piece F can be adjusted in a horizontal direction by means of the screw G. The piston-rod H is connected near the middle of this latter connecting-rod. Since the crank is of constant length, the horizontal adjustment of the piece F alters the length of the stroke given to the piston-rod H. By this means the expansion ratio at each stroke in the working chamber K can be adjusted while the instrument is in operation.

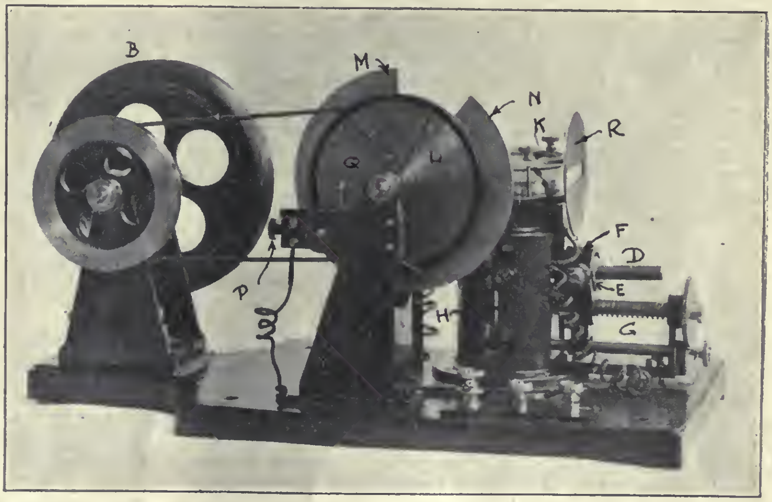

FIG. 1.—Shimizu expansion apparatus.

In order to obtain a good picture of the rays which become visible at each expansion by the formation of linear clouds on the ionised particles in the ray tracks, it is necessary that these clouds be dissipated during the compression stroke. This is done by forming a vertical electrostatic field in the expansion

chamber. The upper glass plate of the expansion chamber, through which the tracks are observed or photographed, is covered on the inside with a gelatine film, which is made conducting. This film is charged negatively with reference to the metal piston, but by means of the commutator L, which rotates with the driving crank, the plate is discharged just before the occurrence of the cloud formation. In the same way as the expansion ratio can be adjusted while the instrument is running, so the length of the period during which the electric field is cut off can also be adjusted while the instrument is running by means of the screw P, which traverses the contact brush along the commutator L, which is shaped, as will clearly be seen in the illustration, in the manner required to give this adjustment. Also rotating with the crank are two adjustable lead segments, M and N, which can be used as shutters for admitting X-rays to the expansion chamber at the proper intervals. It is on the back of the disc carrying these segments that the commutator L, above described, is fitted.

The expansion chamber is fitted with a small tube, by means of which radio-active matter can be introduced into the chamber for the production of α- or β-rays. The present chamber is made 55 mm. in diameter, which is, of course, less than the length of the tracks of some of the α-rays in air, but the velocity of the α-rays can be reduced by passing them through a mica screen. A small screen can also be placed on the piston to cut off the α-rays, except at the moment of greatest expansion. The expansion chamber must be perfectly airtight, as the minutest lag produces eddy currents, which at once destroy the tracks. The instrument is very quickly set up and easily operated, as a few expansions serve to filter out any dust originally in the air. The piston forming the floor of the expansion chamber is covered with a comparatively thick layer of gelatine containing about 10 per cent. of Indian ink. This gives a good black background, against which the tracks show up brilliantly. For demonstration purposes a Pointolite lamp gives excellent results, but for photography a rather more brilliant lamp is desirable. The apparatus is illuminated by means of a parallel beam of light coming in on the left-hand side. The screen R cuts off all light, except a small rectangular pencil passing through the middle of the expansion chamber.

Mr. Shimizu has taken some stereoscopic pictures on kinematograph film with his original apparatus, and by means of these stereoscopic pictures the exact paths of the particles in space can be calculated. The Cambridge and Paul Instrument Co., Ltd., hopes shortly to bring out a suitable stereoscopic camera as an accessory to the expansion apparatus.

Scientific and other Aspects of Beer.

ADRIAN BROWN, the first professor of the first established university school of brewing in this country, died nearly two years ago, and no one more suitable than Prof. Armstrong could have been chosen to pay a tribute to his memory.[1] Prof. Armstrong's enthusiasm for the application of chemistry to biology is undimmed by age; his memories and friendships reach back further than most men's, and (may it be added in a scientific journal?) he has a fine appreciation of the glories of beer. He feels he has observed what would have been Adrian Brown's wish, in making his eulogy be "less of the man than of the yeast-cell," more of the school than of the teacher. After some biographical details and personal reminiscences going back to the 'sixties, he discusses Adrian Brown's scientific work, placing that on the barleycorn first. There is a variety with a blue layer of cells underlying the thin outer skin of the corn; the blue colouring matter behaves like litmus, and is turned red by acids; yet when the grains are soaked in dilute acid they remain blue, for only water enters. This discovery enabled Adrian Brown to study a semi-permeable membrane in a living object and to examine the behaviour of a large number of substances towards it. Water is absorbed from a saturated salt solution, but the more dilute the solution the more rapidly is water taken up. Sugar, strong acids, and strong alkalis also give up the water in which they are dissolved without entering themselves. On the other hand, weak acids, also weak bases, such as ammonia, and chemically neutral substances, like alcohol and chloroform, readily pass through the membrane. Prof. Armstrong suggests that only the simple "hydrone" molecules of water, which alone are considered by him to have the formula H_2O, penetrate the membrane; complexes like H_4O_2 and H_6O_3 are held back. Cane-sugar is held back by the membrane of the barleycorn, yet it passes through the walls of the yeast-cell!

[1] Adrian Brown Memorial Lecture, "The Particulate Nature of Enzymic and Zymic Change." By Henry E. Armstrong. Delivered at Birmingham University on February 18. (Journ. Inst. of Brewing, 1921, vol. xxvii., pp. 197–260.)

Brown's investigation of the oxidative action of *Mycoderma aceti* and *B. xylinum* leads Prof. Armstrong to an account of Bertrand's work on the bacterial oxidation of sugars; similarly his researches on enzymes lead to a review of older and newer work on heterogeneous catalysis, the kinetics of enzyme action, and the mechanism of alcoholic fermentation.

But chemists who know the lecturer and are already more or less acquainted with the ground he covers will turn with the greatest interest to the section on "Beer as a Dietetic." Fortified by quotations from Calverley and from Prof. Saintsbury's recent "Notes on a Cellar-Book," he inveighs against State regulation of the brewing industry and against prohibitionists. It may have been stern necessity, but Government control has rendered beer "little short of worthless as a drink." Lord D'Abernon's committee does not escape, and is accused of verbal quibbling in its report. "The most malign of the attempts to influence opinion is probably that of the Board of Education, in the form of the syllabus of 'Lessons on the Hygiene of Food and Drink for Use in Schools and Notes for the Assistance of Teachers,' issued over the name of Sir George Newman." Later Prof. Armstrong calls out: "Is all æsthetic pleasure to be taken out of life? Are we to treat our food with the contempt we show to the coal we cast upon the fire? Are the views of an entirely selfish, unthinking minority to prevail?". And then comes his answer: "No, I believe our philosophy to be summed up in the familiar lines:—

> Man wants but little here below,
> But likes that little good."

After this we go back once more to science, to a historical review of the science of brewing. The debt we owe to Pasteur is sympathetically explained to a general audience, but those who are already acquainted with the work of the great Frenchman will perhaps learn most from the survey of the "Burton period" and the author's reminiscences of Henry Böttinger, Horace and Adrian Brown, Peter Griess, and O'Sullivan. This chapter in the history of English chemis-

try, or rather of chemistry in England—for the Browns are the only Englishmen in it—should be read by the younger generation of to-day. Two photographs show us the now unfamiliar features of Griess and of O'Sullivan.

Finally, Prof. Armstrong gives us his views on the best methods for promoting biological inquiry and on the research scheme of the Institute of Brewing. Much of what he says about this is of wider application, and bears on scientific research in general. His views, expressed with great conviction, should be especially considered at the present time, when all kinds of new research schemes are being started. Some of us cannot always agree with Prof. Armstrong, but we must all recognise that, if provocative, he is stimulating; if a fighter, he is sincere. And he is also picturesque; he does not bore us. Hence this memorial lecture derives a personal interest from the author no less than from his subject, and thereby its value has been increased.

The Ancient and Modern Inhabitants of Malta.

AT a meeting of the Royal Anthropological Institute held on June 28, Mr. L. H. Dudley Buxton read a paper on "The Ancient and Modern Inhabitants of Malta." The paper was a summary of the results of a small anthropological expedition from Oxford which visited Malta in the winter of 1920–21. The expedition was made possible by the generosity of Sir Alfred Mond and by a grant from the Mary Ewart Trust. The work in the island was offered every facility by the Governor, Field-Marshal Lord Plumer, and his staff, and Prof. Zammit, the Rector of the University, put his unrivalled knowledge of all things Maltese at the service of the expedition.

The history of Malta is bound up with its geographical position, lying as it does on a buttress of the old land bridge between Africa and Sicily. The cave of Ghar Dalam, which is being explored by Mr. Despott, may throw considerable light on man's early history in the island. At present, however, the earliest large collection of human remains belongs to the Neolithic, or more probably Æneolithic, age of the great Maltese megalith builders. Although this culture is, to a certain extent, unique, it offers possible comparison with the *allées couvertes* of Western Europe. The site of Bahria, which has not yet been properly excavated, may provide a link between the Neolithic and the Bronze ages, remains of which have been discovered actually on top of the Neolithic remains at Hal Tarxien. The following periods, the so-called Phœnician or Punic, show a close connection with North Africa—a connection which was not broken until the Roman occupation. At the division of the Empire in A.D. 395 Malta was allotted to Byzantium, to which it belonged ethnologically. It was held successively by the Arabs and by the various occupants of the throne of Sicily until handed over by Charles Quint to the Knights of St. John of Jerusalem in 1530. The Knights held it until 1798, when they were dispossessed by Napoleon. It was occupied by the British in 1800, and formally annexed in 1814.

The megalith builders appear to belong to what is generally known as the Mediterranean race. They show close affinities to the inhabitants of North Africa and Sicily. Probably at the close of the Bronze age—but the exact line is as yet uncertain—a crucial change came over the population and a new type of folk appeared, the contour of whose cranial vault suggests Armenoid characters. In spite of the constant infusion probably of North African blood in Punic times and of Italian during later periods, this type has survived in the islands of Malta and Gozo until to-day.

A study of the modern people shows several remarkable facts: first, that though there are significant differences between the Maltese and the inhabitants of Gozo, there is practically no difference between the inhabitants of the urban and rural districts taken as a whole. The inhabitants of Valetta and the suburbs, contrary to expectation, do not show more variation than the country districts. Two villages, Zurrico and Siggewi, each taken singly, showed as great, if different, variations from the urban districts as did the men of Gozo from those of Malta, but here again the people of tiny and, to a large extent, endogamous villages were only slightly less variable than those of a cosmopolitan port.

It may be said then that, generally speaking, and subject to certain reservations, the Maltese present a well-marked racial type—unlike their nearest neighbours except in Neolithic times, and much more alien to the Cretans and the inhabitants of the "Islands of the Sea."

The Rothamsted Experimental Station.

VISIT OF COUNTY AGRICULTURAL COMMITTEES.

ON Friday, July 15, representatives of the county agricultural committees and directors and principals of the agricultural colleges visited the Rothamsted Experimental Station at the invitation of Lord Bledisloe, chairman of the Lawes Agricultural Trust Committee, and Dr. E. J. Russell, director of the station. They were met by Sir David Prain, Prof. H. E. Armstrong, of the committee of management, and Messrs. T. H. Riches, Leonard Sutton, and other members of the Council of the Society for Extending the Rothamsted Experiments. No more representative party has visited Rothamsted since the great jubilee celebrations of 1893, after fifty years of work had been accomplished. The visitors inspected the plots and the laboratories, and saw practically the whole of the work which is being carried out.

The Rothamsted Experimental Station has expanded considerably during and after the war, and it now has a permanent scientific staff of twenty-six members, in addition to skilled assistants for records, library, and office, and an outdoor staff for the farm and experimental plots. The scope of the work has expanded, and now includes the soil and the growing plant in health and disease. In the main the work falls into two great divisions, carried out respectively in the laboratories and in the fields, with the pot-culture house serving as a close link between them.

In welcoming the visitors Lord Bledisloe stated that this gathering was typical of many which it was hoped to arrange in future years, and its purpose was to make the work of Rothamsted known to those most intimately associated with the development of British agriculture. The most hopeful method of helping the farmer was to furnish him with knowledge about the crops and soils with which he has to deal, and to carry out tests which he could not possibly do for himself. Lord Bledisloe referred

particularly to some of the recent Rothamsted experiments, showing that the addition of chalk to the soil caused so marked a disintegration that the drawbar pull on the tractor was reduced from 1500 lb. to 1300 lb. for the three-furrow plough, thereby reducing the consumption of fuel and the wear-and-tear.

Sir Daniel Hall described the relationships between research stations and the college and farm institutes on the one hand, and the county advisers on the other. He impressed upon his hearers the fact that much of the work of an experimental station could have no immediate practical application, and yet it was absolutely essential for the development of agricultural science and for further advances in agricultural practice. He described the great changes that had taken place in the past fifteen years in the attitude of Government departments towards research work, and to the broader and more enlightened outlook on the part of the general public.

Dr. Russell described the work of the station, and emphasised the fact that its purpose is first to obtain trustworthy information about the soils and growing plants, and then to put this information into such a form that teachers and experts can use it. Among recent developments to which Dr. Russell referred are the statistical department, where elaborate and extensive Rothamsted data are examined by modern statistical methods, and the work on cultivation which is now being carried out by the physical department and the farm.

University and Educational Intelligence.

DURHAM.—The following honorary degrees were conferred upon members of the British Medical Association on July 21:—*Doctor of Civil Laws*: Sir William MacEwen, Sir Thomas Oliver, and Sir Humphry D. Rolleston. *Doctor of Hygiene*: Dr. T. E. Hill and Dr. J. W. Smith. *Doctor of Science*: Sir Arthur Keith. *Doctor of Literature*: Sir Dawson Williams, editor of the *British Medical Journal*. *M.A.*: Dr. Alfred Cox, medical secretary of the British Medical Association.

LONDON.—Mr. M. T. M. Ormsby has been appointed as from August 1, 1921, to the Chadwick chair of municipal engineering tenable at University College. Mr. Ormsby was appointed assistant to Prof. Osbert Chadwick at the college in 1898, and since 1914 has been University reader in surveying.

Dr. F. S. Langmead has been appointed as from August 31, 1921, to the University chair of medicine tenable at St. Mary's Hospital Medical School. Dr. Langmead has held a number of posts at St. Mary's Hospital since 1902, also at the Hospital for Sick Children and at the Seamen's Hospital, Greenwich.

The Rogers Prize of 100*l.* for 1921 has been awarded to Mr. Lambert Rogers for an essay entitled "The Surgical Treatment of Hyperthyroidism."

The following doctorates have been conferred:—*D.Sc. in Physics*: Mr. Lewis Simons, an internal student, of King's College, for a thesis entitled "Contributions to the Study of Energy Transformations when X-radiation is absorbed by, or emitted from, a Substance." *D.Sc. (Engineering)*: Mr. K. C. Chakko, an internal student, of University College, for a thesis entitled "Stresses in Chain Links." *D.Sc. in Botany*: Mr. Birbal Sahni, an external student, for a thesis entitled "The Structures and Affinities of *Acomopyle Pancheri*, Pilger." *D.Sc. in Chemistry*: Mr. W. C. Reynolds, an external student, for a thesis entitled "On Interfacial Tension." *D.Sc. in Geology*: Mr. L. F. Spath, an external student, for a thesis entitled "On Cretaceous Cephalopoda from Zululand," and other papers; and Mr. L. D. Stamp, an external student, for two theses entitled "On the Beds at the Base of the Ypresian (London Clay) in the Anglo-Franco-Belgian Basin," and "On Cycles of Sedimentation in the Eocene Strata of the Anglo-Franco-Belgian Basin."

THE Trustees of the Beit Fellowships for Scientific Research, which were founded and endowed in 1913 by Sir Otto Beit in order to promote the advancement of science by means of research, have recently elected to fellowships Messrs. H. L. Riley and W. A. P. Challenor. Mr. Riley was educated at the Keighley Trade and Grammar School, 1910–17, and has been a student at the Imperial College of Science and Technology from 1919 to date. Mr. Challenor was educated at Whitchurch Grammar School, 1911–17, and has been a student at the Birmingham University from 1917 to date. Both will carry out research at the Imperial College of Science and Technology at South Kensington.

IT was announced in NATURE of July 7, p. 604, that Mr. H. H. Wills had presented the University of Bristol with the sum of 200,000*l.* for the provision of a new physics laboratory. Further particulars have now been received. Two gifts totalling 200,000*l.* were received, and the Council of the University has now approved plans and signed a contract for the erection of a building. It is estimated that the work will absorb the whole of the original gifts, together with the interest on the fund, amounting to 21,000*l.*, which has since accrued. The Council has further decided to associate the name of Mr. Henry Wills permanently and for all time with the department by naming the building "The Henry Herbert Wills Physical Laboratory." In this Bristol is following the precedent of other universities in associating the name of the donor with a laboratory erected by him for a particular subject. The building, which is Early Renaissance in style, will be a four-floor structure in the shape of the letter "L," to be erected on the north-east side of the Royal Fort Estate. The architects have been most successful in securing both architectural beauty and all the facilities of light and other special requirements demanded by a science department. When it is erected Bristol will possess the best building for teaching and research work in physics in the world. The total amount contributed to the University of Bristol by various members of the Wills family now exceeds 900,000*l.*

SIR MICHAEL SADLER, Vice-Chancellor of the University of Leeds, in the course of an address after opening the new buildings of the Community of the Resurrection at Mirfield on July 16, said that modern civilisation was one of the colossal facts in the world's history. It had been achieved by the courage and labour of Western men during four centuries. Its essence was power. Its phases had been the power of the individual pioneer, the power of the State, the power of the sea, the power of the machine, the power of coal, and the power of high explosives. Through this stupendous outburst of power Providence had permitted a great change in the lives of men and in the outlook of their minds. It had quickened invention; it had flowered in great literature; it had multiplied opportunity; it had created wealth beyond even the dreams of avarice. Of the six most brilliant epochs in human history modern Western civilisation had been one. But now in its heart and conscience there is foreboding. Power, which is the essence of modern civilisation, threatens to destroy it. Three men so typical as Viscount Grey, Mr. H. G. Wells, and the Dean of St. Paul's

warn us that modern civilisation is at the cross-roads of its destiny. Unless, by some deflection of its recent purpose, power can be concentrated upon the constructive works of peace, it will destroy civilisation by war. At this moment the Middle Ages seem to whisper once more the message of an ideal which in modern times most men have discarded or have tried, however wistfully, to forget. In industry men begin to think of the medieval guilds. In art the naive sincerity of the primitive painters inspires some of those moderns whose pictures are religious. In politics men speculate as to the possibility of a Council of the Peoples which may recognise nationhood, but allay its rivalries. We cannot go back to the Middle Ages and become medieval in all our thought and way of life. But it is possible that the future may blend some medieval ideas with those derived from the age of power, and that what is perilous in some modern tendencies may be transmuted by a rediscovery of some aspects of truth better known to the medieval than to the modern mind. To the medieval thinker three mysterious powers sustained, by their harmonious working, the life of Christendom. They were called the priesthood, the Empire, and the university: Sacerdotium, Imperium, and Studium. For all three in a form adapted to modern needs the modern world may find a place.

The recent annual meeting of the council of the Association of University Teachers was held at Bedford College, London, and was well attended by delegates from the various university institutions of England and Wales. The president, Prof. John Strong, of the University of Leeds, in his retiring address indicated the general aims of the association, the lines on which it has been working, the progress made, and some of the more important problems opening up. The primary aims were the advancement of knowledge and the furtherance of the interests of the universities. So long as the universities were in difficulties regarding finance, so long would their work suffer. Such questions as teachers' salaries and superannuation were, under present conditions, insistent. The superannuation question had not been settled by the recent grant from the Treasury, nor was the problem of salaries yet solved, although progress towards a solution was apparent. Apart from these, other and equally serious questions were arising. The relation of the universities to the State and to the local authorities would demand more and more serious consideration. While greater financial support from the Government was imperative, the matter of similar and more uniform support from the local education authorities was urgent. The suggestion of a uniform local rate being levied upon all the local education authorities had much to be said in its favour, but, among other things, it would mean increased local representation. Consideration of these points gave rise to the question of the possible infringement of the present autonomy of the universities—a matter of vital importance to the teaching body. Any such possibilities would have to be watched carefully by the universities. The officers and executive committee for the coming year were elected as follows:—*President:* Prof. John Strong (Leeds). *Vice-Presidents:* Prof. McBain (Bristol) and Mr. F. Boulden (Sheffield). *Treasurer:* Asst. Prof. Tabor (Imperial College). *Hon. General Secretary:* Mr. R. D. Laurie (Aberystwyth). *Executive Committee:* Prof. Calder (Manchester), Prof. Dame Helen Gwynne-Vaughan (Birkbeck College), Mr. Haigh (Reading), Miss Halket (Bedford College), Prof. Lea (Birmingham), Prof. Mair (Liverpool), Mr. Monahan (Leeds), Prof. Orton (Bangor), Asst. Prof. Philpot (University College, London), and Prof. Truscott (Imperial College).

Calendar of Scientific Pioneers.

July 28, 1818. Gaspard Monge, Comte de Péluse, died.—The creator of descriptive geometry, Monge was a prominent figure through the whole of the Revolutionary period. He had a great share in founding the Ecole Polytechnique, and, like Berthollet, was a favourite of Napoleon. At the Restoration he was expelled from the Institute on account of his having voted for the death of Louis XVI.

July 29, 1751. Benjamin Robins died.—A mathematician of distinction, Robins invented the ballistic pendulum and carried out a series of experiments which marks an era in the history of gunnery. He died at Madras as chief engineer to the East India Company.

July 29, 1869. Joseph Beete Jukes died.—A favourite pupil of Sedgwick, Jukes became naturalist to H.M.S. *Fly* in Australia (1842–46), and from 1850 was director of the Geological Survey of Ireland.

July 29, 1885. Henri Milne-Edwards died.—Milne-Edwards filled the chairs of entomology, zoology, and physiology at the Jardin des Plantes, studied the natural history of the coasts of France and Sicily, and wrote valuable works on the Crustacea, on the corals, and on physiology and comparative anatomy.

July 29, 1898. John Alexander Renia Newlands died.—One of the first to indicate that the properties of the elements are related to their atomic weights, Newlands practised in London as an analytical chemist.

July 30, 1832. Jean Antoine Chaptal, Comte de Chanteloup, died.—A member of a wealthy family, Chaptal engaged in practical chemistry, and during the Revolution superintended the manufacture of gunpowder. Under Napoleon he served as Minister of Instruction, and did much to further the industrial arts and manufactures of France.

July 30, 1913. John Milne died.—For twenty years professor of geology and mining at the Imperial College of Engineering, Tokyo, Milne made an exhaustive study of earthquakes. He founded the Seismological Society of Japan, invented various instruments, and contributed numerous papers on seismology to the British Association and other bodies.

July 31, 1839. Gaspard Clair François Marie Riche, Baron de Prony, died.—A famous member of the Corps des Ponts et Chaussées, Prony during the Revolution directed the compilation of extensive logarithmic tables. He became a professor at the Ecole Polytechnique, and was employed on many civil engineering works of importance. The Prony friction dynamometer was his invention.

August 1, 1769. Jean Chappe d'Auteroche died.—An assistant astronomer of the Paris Academy of Sciences, the Abbé Chappe d'Auteroche observed the transit of Venus of 1761 at Tobolsk, Siberia, and that of 1769 at St. Joseph, California, where he died of fever brought on by his exertions in the interest of science.

August 2, 1823. Lazare Nicholas Marguerite Carnot died.—Carnot began life as a military engineer. He helped to found the Ecole Polytechnique, and was one of the first members of the Institut de France. His work of 1803, "Géométrie de position," gives him a place beside Monge and Poncelet as one of the founders of modern geometry, and as a military engineer he is remembered for his great work on fortifications.

August 3, 1770. Guillaume François Rouelle died.—As professor of chemistry in the Jardin du Roi, Rouelle attracted much attention by his lectures and his new ideas. Lavoisier and Proust were among his pupils.

E. C. S.

Societies and Academies.

London.

Faraday Society, June 22.—Prof. A. W. Porter, president, in the chair.—C. J. **Smithells** (for the Research Staff of the General Electric Co.): High-temperature phenomena of tungsten filaments. Part i. Two types of tungsten wire are in general use for lamp filaments. One is composed of pure tungsten, and the other of tungsten containing up to 1 per cent. of a refractory oxide such as thoria. The crystal growth during burning has been investigated for both types. It is shown that the deformation of the filament which occurs during life is a function of the crystal growth. Crystal growth, which is suppressed in thoriated filaments, occurs when the thoria is reduced. Thoria and other refractory oxides can be reduced by phosphorus vapour at a high temperature. Part ii. deals with the chemical reactions which occur in gas-filled tungsten filament lamps when traces of the common gases are present in the filling gas.—E. **Hatschek**: A simple apparatus for determining the coagulation velocity of gold sols. The percentage of blue formed in coagulation of red gold sol is taken as a measure of the degree of coagulation. The percentage is determined by comparing the original red sol with a double wedge, one half consisting of the original sol, and the other of the completely coagulated blue sol. It is necessary that the latter should be coagulated by the same electrolyte as that used in the sol under examination, as the blues obtained with different electrolytes are not exactly alike. A number of determinations have been compared with V. Smoluchowski's formula for the coagulation velocity, and show good agreement for complete and fairly rapid coagulation.—Prof. A. W. **Porter**: The variation of surface tension and surface energy with temperature. Any satisfactory formula must correspond with the vanishing of both the surface tension σ and the surface energy u at the critical point. The connection is $u=\sigma-T\frac{\partial\sigma}{\partial T}$; hence $\frac{\partial\sigma}{\partial T}$ must also vanish at the critical point. These conditions are all satisfied by the formula put forward by van der Waals, and afterwards by Allan Ferguson, viz.

$$\sigma=\text{constant }(T_c-T)^n,$$

where n is a constant between 1·2 and 1·3. Whittaker has shown that u is proportional to T × internal latent heat. The author shows that if the reduced temperature be taken as the factor (instead of T), the numeric values show that for many substances u and the internal latent heat of evaporation tend to equality (on the C.G.S. system) as the temperature is approached. He also directed attention to the connection between van der Waals's equation for σ and Thiessen's equation for the latent heat, $\sigma=\text{constant }(T_c-T)^m$, where m is about 0·3.—S. M. **Neale**: The influence of solvent upon ionisation and the accompanying heat effect. A determination by electrical conductivity methods of the ionisation of picric and *para*nitrobenzoic acids in mixtures of acetone and water. From the values obtained at 25° and 35° C. the heats of ionisation are calculated. In the case of picric acid the heat of ionisation varies largely with the nature of the solvent, passing through a minimum at about 70 per cent. acetone. In the case of *para*nitrobenzoic acid the heat of ionisation is sensibly zero both in water and in 44 per cent. acetone, although in the latter solvent the ionisation constant has fallen to 1/20th of its value in pure water as solvent.—A. **McKeown**: The potential of the iodine electrode and the activity of the iodide ion at 25° C. The potential of the saturated iodine electrode in combination with the normal calomel electrode has been measured for various values of the concentration of the iodide ion. The results have been compared with those of other investigators, making use of the concept of activity coefficient; the activities of the iodide and of the tri-iodide ion in the various solutions have been estimated and compared with the values of the concentration of these ions. It is found that the activities of both ions increase less rapidly than their concentrations. From the results the normal potential of the iodine electrode is calculated to be +0·2454 volt, the normal calomel being taken as zero.

Paris.

Academy of Sciences, July 4.—M. Georges Lemoine in the chair.—The president announced the death through a motor-car accident of Jules Carpentier, free member.—G. **Lemoine**: The mutual reaction of oxalic acid and iodic acid. The influence of different catalysts. As catalysts, platinum sponge, platinum black, wood charcoal, and sugar carbon were used. In general, for the same reaction velocity a higher temperature was necessary in the absence of a catalyst. Increasing the weight of catalyst increased the reaction velocity, but this was proportional neither to the weight nor to the surface. The activity of the platinum black was very great in proportion to the other substances.—A. **de Gramont**: Spectra of quantitative sensibility of silicon in fused salts and in steels. Working with fused salts, two characteristic lines of silicon persist down to a content of 0·005 per cent. of silicon. With steel, the sensibility is less on account of the brightness and number of the iron lines.—P. **Sabatier** and B. **Kubota**: The action of heat on allyl alcohol in presence of various catalysts. There are two main reactions, dehydrogenation and dehydration; copper and manganous oxide especially effect the first of these, and tungstic acid, thoria, and alumina the second. With zirconia and uranic oxide both reactions occur together. Owing to secondary changes the final product is very complex, and contains water, acrolein, propyl aldehyde, higher aldehydes formed by condensation, and hydrocarbons (mesitylene). The gases include propylene, hydrogen, carbon monoxide, and dioxide, but neither acetylene, allene, nor allylene could be detected.—B. **Gambier**: Imaginary surfaces applicable to a surface of revolution; real corresponding cyclic systems.—D. **Riabouchinski**: The cyclic movement of a liquid round a solid which moves parallel to a rectilinear wall.—J. **Mascart**: Observation of the occultation of Venus of July 1, 1921, made at the Observatory of Lyons. Observations were made under good atmospheric conditions by six observers with different types of instrument.—E. **Belot**: The law of rotation of the sun explained by evolution and flattening of the proto-sun.—M. **Brillouin**: Bohr's atom. The circumnuclear Lagrange function.—A. **Lafay**: The figures of M. de Heen and the electric discharge.—M. **Solomon**: A radiological ionometric arrangement. A description of an apparatus for the measurement of ionisation in medical radiology. It is standardised by a known quantity of radium.—A. **Dauvillier**: The principle of combination and the absorption lines in the X-ray spectra.—A. **Marcelin**: Surface tension of the monomolecular layers.—A. de G. **Rocasolano**: Variations of catalytic power in the electroplatinosols.—G. **Tanret**: An ammonium molybdo-quinate. Quinic acid is known to show a marked increase in rotatory power when mixed with solutions of molybdates. This is due to the formation of a definite complex compound, ammonium molybdo-quinate, the isolation and analysis of which are described.—J. **Cvijić**: The correspondence

of the fluvial steps and river-banks.—R. **Souèges**: The embryogeny of the Labiates. Development of the embryo in *Glechoma hederacea* and in *Lamium purpureum*.—P. E. **Pinoy**: The germination of the spores, the nutrition, and the sexuality of the Myxomycetes.—Mme. Z. **Gruzewska**: The mucilaginous substances of *Laminaria flexicaulis*. Nitrogen does not appear to be an essential constituent of the mucilage; hydrolysis is slow, the sugar formed being glucose or galactose.—G. **Bertrand** and R. **Vladesco**: The variation in the proportion of zinc in the organism of the rabbit during growth. The proportion of zinc contained in the entire body of the rabbit is a maximum at birth, diminishes during the period of lactation, and then, after the twenty-fifth day, on weaning, the zinc increases rapidly.—H. **Bierry**, F. **Rathery**, and Mlle. **Levina**: The proteid sugar in cancerous subjects. The amounts of free sugar and proteid sugar in the blood-plasma of ten cancerous subjects have been determined. The proteid sugar is from twice to four times the normal amount.—M. **Aron**: The existence and *rôle* of an endocrinian tissue in the testicle of some Batrachians.—C. **Pérez**: A new Ceponian, *Onychocepon harpax*, a branchial parasite of Pinnotheres.—H. **Faes** and M. **Staehelin**: The resistance of the adult cockchafer to low and high temperatures. The adult cockchafer can be submitted to a temperature down to -8° C. and recover its activity on warming; at lower temperatures it is killed. This insect is more susceptible to high temperatures, since at 45° C. it is killed.

BRUSSELS.

Royal Academy of Belgium, January 8.—M. A. Gravis in the chair.—A. **Demoulin**: The equations of Moutard with quadratic solutions.

February 5.—M. G. Cesàro, president, in the chair.—C. **Julin**: Report of the decisions taken at the meeting of the section of biological oceanography of the International Union of the Biological Sciences.—J. **Massart**: The four steps of sexual conjugation.—P. **Stroobant**: Complementary note on the nature of the temporary stars.—C. **Servais**: A group of three tetrahedra.—P. **Nolf**: The action of chloroform on the coagulation of the blood plasma of birds. Antithrombosine is generally considered the physiological antagonist of thrombine, its function being to neutralise this substance wherever it is in excess. This is not found to be in accord with the experiments described. It would appear that antithrombosine, instead of neutralising thrombine, contributes to its formation.—Th. **de Donder**: The *gravific* field.—L. **Godeaux**: Researches on the cubic involutions belonging to an algebraic surface.—F. **Carpentier**: The prothoracic endo-skeleton of *Gryllotalpa vulgaris*.

March 5.—M. G. Cesàro, president, in the chair.—A. **de Hemptinne**: The law of Faraday, and the action of the silent electric discharge on the metallic oxides. An account of experiments in which the oxides of lead, copper, nickel, and mercury are exposed to the silent discharge in an atmosphere of hydrogen under reduced pressures (10 to 30 mm.).—E. **van Aubel**: (1) The atomic heat of the elements. According to a recent communication by M. Félix Michaud, the atomic heat should have the value 3·5 for a temperature corresponding to a maximum of the quotient CA/T (where C is the specific heat, A the atomic mass, and T the absolute temperature). An examination of the values for silicon, boron, rhombic sulphur, thallium, magnesium, and chromium shows that these substances are not in accordance with M. Michaud's rule. (2) The density and refractive index of mixtures of aldehyde with water or ethyl alcohol.—C. **Servais**: Quadrics of revolution conjugated to a tetrahedron.—E. **Henriot**: The variation of the refractive index of liquids with density.

April 9.—M. G. Cesàro, president, in the chair.—G. **Cesàro**: Some new forms of orpiment from Balia, Asia Minor.—C. **Servais**: A curve of the third order associated with a triangle.—P. **Stroobant**: Observation of a shooting star at Brussels.

May 3.—M. G. Cesàro, president, in the chair.—M. **Stuyvaert**: An element analogous with a curvature at a point external to a plane algebraic curve.—L. **Godeaux**: Some linear congruences of skew cubics considered by M. Stuyvaert.—P. **Bruylants**: The action of the organo-magnesium compounds on glutaric nitrile. This nitrile behaves as a pseudo-acid, and on acidifying the reaction product nearly the whole of the nitrile is recovered. There is a secondary reaction producing a very small quantity of a ketone, probably $C_2H_5.CO.(CH_2)_3.CN$.—H. **Vanderlinden**: The *gravific* field of an electrified sphere.

ROME.

Reale Accademia nazionale dei Lincei, May 8.—F. D'Ovidio, president, in the chair.—Papers by fellows:—C. **Somigliana**: Depth of glaciers, i. The equations of motion are found for a glacier, and are identical in form with those of a viscous liquid moving slowly in a tube inclined to the horizon. This very natural conclusion is justified by the property that the velocity of the glacier is considerably less than the critical velocity at which fluid motion becomes turbulent. It might be suggested, however, to Prof. Somigliana that the cracking of the ice substitutes another effect limiting the applicability of the equations in this case.—F. **Severi**: Integrals of first species, v.—O. M. **Corbino**: Thermal analogue of Oersted-Ampère effect, ii.—Papers communicated through a fellow:—G. **Abetti**: Astronomical determinations of latitudes and longitudes in Central Asia. These were carried out in De Filippi's expedition in 1913–14 by the author and Comdr. A. Alessio, the longitudes being referred to the meridian of the transit circle of Dehra Dun by wireless signals from the Trigonometrical Survey of India. The observations were made at the following stations: In Baltistan at Tolti, Wazul Hadur, Scardu, and Càrghil; in Ladak at Lamairu and Leh; in Caracorùm at Depsang and the front of the Rìmu glacier (altitude 4912 metres); and in Turkestan at Sughèt Carol, Jàrcand, and Càshgar.—C. **Perrier**: Presence of zinc in the malachite of Chessy. A comparison of malachite and the new mineral rosasite is given.—C. **Gorini**: Proteolitic activity of lactic ferments, v. Phenomena of rapid physiological mutation.—D. **Maestrini**: Enzymes, vi. Protective power of starches and other substances on phthalin in acid media.—J. **Pérès**: "Transformations qui conservent la composition." A sequel to the author's previous contributions in the *Annales de l'Ecole normale supérieure* and *Bulletin de la Société mathématique de France*, published in 1919.

SYDNEY.

Royal Society of New South Wales, June 1.—Mr. E. C. Andrews, president, in the chair.—A. R. **Penfold**: The occurrence of a new phenol in the essential oils of the Leptospermum. In the course of the examination of the essential oils obtained from *Leptospermum flavescens* growing in various parts of New South Wales, a phenolic body was found to occur in amounts varying from 0·75 to 8 per cent., the latter being obtained from material growing in the Lane Cove (Sydney) district. It has been named "Leptospermol."

Modern Credulity.

DURING the last ten or twelve years there has been a remarkable recrudescence of the amulet, or mascot. Nowadays there must be few collections of jewelry which do not contain at least one piece for luck, whether it be a four-leaved shamrock, an effigy of a pig, cat, or other animal in one of the precious metals, a holed coin inset with a turquoise or other stone, real or imitation, or some similar object to which protective properties are attributed in some degree. It must afford a peculiar joy to Sir William Ridgeway to see his theory of the magical element in primitive jewelry translated into actual practice in civilised conditions. The more grotesque or bizarre the object, the greater the attachment of the owner. Hence the remarkable forms taken by ornaments in china and other material. Nor need the mascot be an inanimate object. Dogs, cats, monkeys, and other animals are pressed into service. In Paris hunchbacks have a regular *clientèle* among stockbrokers, who make a point of touching the deformity before an important deal; while one French actor is said always to have a hunchback in his dressing-room during a first night.

The mascot appeals in particular to those whose pursuits expose them to risk or to the effects of chance. It is quite in keeping that their use should be particularly prevalent among those addicted to betting and card-playing, among members of the theatrical profession, and among motorists. In the case of the last-named the practice is perhaps more common in France and the United States; but even in this country, at one time, quite a considerable proportion of cars carried a "Teddy" bear, a black cat, a golliwog, or a policeman on the bonnet. The fact that applications have been entered for patent rights in special types of improved mascots and luck-charms suggests a sense of humour not without cynicism in the would-be patentees.

During the war the belief in the efficacy of mascots was both extended and intensified. The Army has always had a certain inclination towards some form of luck-bringer, which, more often than not, is the regimental pet. The goat of the Royal Welsh Fusiliers is perhaps the best-known example. The recognised use of the mascot in the Army, however, is collective rather than personal; and it was the personal use which became so prominent during the war. It extended to the whole community, and not merely to those on active service. There were few into whose lives the elements of luck and chance did not seem to have entered with a tragic significance which was absent before the war.

The mascot is not the only form taken by an interest in the occult. Apart from the serious study of telepathy and other forms of psychic manifestation, as well as the more or less religious belief in faith-healing, there was, before the war, a great deal of half-frivolous and wholly superstitious belief in crystal-gazing, palmistry, and other means of foretelling the future which afforded an opportunity to innumerable charlatans to prey upon a credulous public. During the last few years, for reasons which are obvious, this interest has assumed a more serious character, and a desire, perhaps not consciously realised, to mitigate the loss of an intimate association has intensified the wish to know something of the life after death and to communicate with those who have "passed beyond." As a result, a mass of evidence has been brought forward which, it is maintained, establishes the possibility of communication with the spirits of the departed, and affords some indication of the character and conditions of existence after death. Investigations have been carried a step further. The evidence is no longer confined to the existence of spirits once embodied in human form. To earth-spirits, elementals, poltergeists, and other influences

which are said to have manifested themselves by various means are now added fairies. Not only have fairies appeared visibly to a certain number of individuals, as reported by Sir A. Conan Doyle, but photographs of them have been taken and published in a popular magazine. The truly wonderful similarity between the real fairy or gnome, as photographed, and the conventional fairy of art is a remarkable tribute to the imaginative genius and insight of such artists as Mr. Arthur Rackham. Sir A. Conan Doyle, whom this resemblance has not escaped, would account for it by a tradition of a previous revelation.

It is clear that these beliefs cannot be treated as being all upon the same level. Mascots are undoubtedly largely a result of fashion, and in a number of cases—probably the majority—the owners would deny any faith in their efficacy. They are "just for luck." The spiritualist, however, holds his convictions with something of the fervour of a religious zealot, yet taking the beliefs as a whole they have one element in common. They represent a reversion to a very primitive point of view.

The revival of the mascot and other forms of the occult has been confined to the upper and well-to-do classes. Among the lower and less educated classes of Europe belief in certain forms of magic has never died out; it goes back to prehistoric times. In the Mediterranean the belief in the evil-eye retains all its old vitality; at Naples, during the current year, an old woman was harried as a witch; and a sheep's head, wrapped in human hair fastened with forty-three large nails, found in her possession, was seized by the police and burned in a church at the request of the excited populace. In the recent elections in Italy a political party of gamblers was formed, also at Naples, of which the chosen representatives were noted for the magical powers which they placed at the service of their clients. In this country the belief in the witch has not died out—in 1906, at Thames Police Court, a reputed witch was convicted of obtaining money by means of a trick, and other cases have occurred since that date. Love-charms and amulets against sickness and misfortune are common. A potato (against rheumatism), an oddly shaped bone, a fossil, a thread of red silk, even a modified phallus in glass or other material worn as a pendant, are objects familiar to the collector. These charms and amulets of the "folk," in both town and country, are more closely akin to primitive belief and less sophisticated than the mascot; but in both cases the psychological basis is identical.

To the anthropologist it is a commonplace that the belief in the efficacy of charms and amulets, like other forms of magic, rests upon ignorance of the operation of cause and effect. In the primitive mind this arises from an imperfect knowledge of natural forces. The owner of a mascot, though not unaware of the relation of cause and effect, ignores it and hopes to influence favourably antecedent conditions which are beyond his personal control. The desire to learn what conditions will prevail in the future, either from mere curiosity or in order that they may be controlled or utilised, as in a stock-exchange gamble or a bet, is responsible for the clairvoyant, the crystal-gazer, and other forms of fortune-teller. A further point of contact with primitive belief is that the use of the mascot implies faith in its efficacy; it has occult powers, a belief which differs in no way from that of the primitive mind that certain individuals and certain objects have *mana*. In the use of the figure of a policeman as a motor mascot we may even see a form of sympathetic magic; by its means the owner may hope to escape the attentions of the real policeman and the snare of the police trap.

A similar parallel can be drawn in the case of the whole-hearted believer in spiritualism. It requires little more than a superficial acquaintance with primitive animistic beliefs and practices to find their counterpart in the mental attitude and outlook of the modern spiritualist, while the medicine-man, especially when, as is often the case, he is endowed with an abnormal mental constitution and associated with a particular spirit or group of spirits, is the prototype of the medium and his "control."

To the sociologist this phase of modern credulity is of the greatest moment. Religion, with the attendant moral codes, has, on the whole, proved one of the strongest factors in the preservation of the social structure. Magic, when once it has served its purpose in the development of human society, has usually been antisocial, while spiritualism, at any rate in some of its recent manifestations, contravenes the generally accepted conceptions of religious belief. A certain amount of intellectual scepticism may be regarded as a healthy and necessary element in any society; but should the place of religion be taken by a reversion on any extended scale to a wholly primitive mode of thought, the prospect affords faint hope of social security and progress.

Education and World Citizenship.

The Salvaging of Civilisation. By H. G. Wells. Pp. 202. (London: Cassell and Co., Ltd.) 7*s.* 6*d.* net.

A BOOK by Mr. Wells, and especially a book on education, is always important. "The Salvaging of Civilisation" is no exception. Part of the book has already been published as a separate essay, part of it consists of lectures to an American audience, and a third part was doubtless prepared for the present volume; but it all fits together, because it all belongs to Mr. Wells's remarkably clear and orderly thought.

In his "Outline of History" Mr. Wells has sketched, in amazingly firm lines, the uncertain origins of our race. In the present book he presents, with the same firm touch, our equally uncertain future. It would be tempting to compare Mr. Wells as historian with Mr. Wells as prophet, for this is a prophetic book. It is concerned with the purpose and future of mankind, but with the distant, rather than with the immediate, future. Mr. Wells has gone scouting far ahead of those whose principal concern is with the next step towards international co-operation and world citizenship. In this volume he tells us what he has seen of the distant goal, but he has little to say of the first practical steps towards it. One thing, however, he is sure about. If the goal is ever to be reached, it is education that will get us there. "The task . . . is not primarily one for the diplomatists and lawyers and politicians at all. It is an educational one."

It is true that thought tends always to end in action, and it follows that deeds are the ultimate (and ideas only the intermediate) product of a system of education. The universities, for example, because of their increasing concern with applied science, especially during the war, are realising that their business is not only to discover and to disseminate knowledge, but also to see that practical effect is given to it. The practical effect here in question is no less than the political reconstruction of the world, so that, as Mr. Wells acknowledges, politicians, as well as educators, have a part to play; but "world-wide educational development and reform are the necessary preparations for and the necessary accompaniments of a political reconstruction of the world. The two are the right and left hands of the same thing. Neither can effect much without the other." But in the beginning, and for most of the way, it is the educator rather than the politician that plays the title-*rôle* in Mr. Wells's outline of history yet to be.

If, then, the end of education, like the end of thought itself, is action, we are not to be educated passively to imagine, but actively to seek, the ideal future for mankind; and our immediate purpose must be "to find release from the contentious loyalties and hostilities of the past which make collective world-wide action impossible at the present time, in a world-wide common vision of the history and destinies of the race." This purpose is to be central and dominant in the outlook that is to result from Mr. Wells's scheme of education. (We remark parenthetically that Mr. Wells's recognition of the supreme importance of purpose in the make-up of character might illustrate, if further examples were needed, how closely many of Mr. Wells's views accord with much that is best in modern thought on education. But there are some of Mr. Wells's opinions that would not obtain assent from those who are most competent to judge. Thus residence and tutorial superintendence were considered by Newman to be of the first importance in university education, but Mr. Wells thinks that an undergraduate of Trinity College, Cambridge, has "no very marked advantage" over an evening student in a northern industrial town.)

Mr. Wells further recognises that, to get things done, there must be unity of purpose among large numbers of men and women, as well as strong purposes dominating each of them individually. "It is manifest that unless some unity of purpose can be achieved in the world . . . the history of humanity must presently culminate in some sort of disaster." But the unity which Mr. Wells rightly demands for the central purposes of men and women the world over, he would also have for a large part of their outlook on the universe. Unity of outlook upon natural science, upon history, and upon literature, as well as upon the aim and purpose of human progress, he would secure by means of common text-books—"The Bible of Civilisation"—always being revised, but always and everywhere in use. Many of his readers will find this suggestion revolting; but they would be ill-advised to reject it without the most careful scrutiny. From many points of view it is far in advance of modern practice. Middle-aged students of mathematics will gratefully remember what Clerk Maxwell called

> Hard truths made pleasant
> By Routh and Besant
> For one who hasn't
> Got too much sense.

The codification of elementary applied mathematics by these great Cambridge coaches enormously facilitated the progress of most students who would otherwise have had to depend upon comparatively incompetent teachers and "over-

much tedious lecturing," as Mr. Wells has it. It created, among Cambridge mathematicians, a school of thought that was probably advantageous to their subject as well as to themselves.

But Mr. Wells's scheme of world-wide education, like the national system of education foreshadowed for England in Mr. Fisher's great Act of 1918, depends for its realisation upon the money being available. Mr. Wells has no doubt where the money is to come from; and, in truth, there can be little doubt about the matter. According to a recent American book, the United States spent last year no less than 93 per cent. of the national revenues upon wars old and new: that is, on war loan charges, on war pensions, and on maintaining military and naval forces. Great Britain, not being made up of forty-eight States with separate incomes, naturally spent a smaller proportion of her national income on war charges; but last year, and again in the Estimates for this year, the proportion of the national revenues that this country is spending on wars old and new is no less than 64 per cent.—more than twelve shillings in every pound of taxes. When we remember that a simple agreement between a few great naval Powers is all that is needed to abolish battleships, and that a battleship costs, in capital, some 8,000,000*l.* sterling, or, in income (for interest, depreciation, and repairs, but not including *personnel*), 1,000,000*l.* a year—more than ten times the British contribution to the League of Nations—we wonder that this money is not diverted to remunerative expenditure. The whole contribution of the British Government to university education is only 2,000,000*l.* (of which half a million pounds is a special grant for superannuation purposes) this year, and used to be much less. It is thus equal to the cost of maintaining the structure and equipment of two battleships. Mr. Wells says that we need to press "for a ruthless subordination of naval, military, and Court expenditure to educational needs." At all events, we need to come to an agreement with the other nations of the world, most of whose incomes are at present insufficient to meet their expenditure, for a general limitation of armaments, that would enormously reduce the burdens of taxation and set free far more than sufficient money to expand and improve our educational organisations as rapidly as is humanly possible.

Mr. Wells's book is marred by minor defects, which are only minor because of the greatness of the whole. Thus he would apparently have his readers believe that the world commonwealth, which he regards as the ultimate goal, should be attained by the immediate absorption of the existing seventy or eighty independent sovereign States of the world into a single super-State. Such a first step would certainly be a false step, even if it were in any way practicable. How would it, for example, be possible to persuade Japan to place the control of her destinies in the hands of a Parliament, Congress, or Assembly most of the members of which would be of European race? The first step towards increasing the political unity of the nations is surely their cooperation in multifarious works for the benefit of mankind, and especially in the abolition of world-war. This is what is being done by the "quite inadequate League of Nations at Geneva," which consists, after all, of forty-eight sovereign States representing three-quarters of the population of the earth.

Moreover, Mr. Wells is surely mistaken in supposing that we must get rid of patriotism if we are to have an adequate sense of world citizenship. Loyalty to a smaller group is not necessarily inconsistent with higher loyalty to a larger group that includes the smaller. An undergraduate who is asked to play for his university and for his college on the same day will play for his university, and not for his college; but he is not on that account less loyal to his college. The Yorkshireman or the Cornishman who loves his county is not on that account an inferior Englishman; nor is one who loves England likely to be a less loyal member of the British Commonwealth of nations than one who has no feeling for his own people; nor, again, has it ever been suggested that loyal members of the British Commonwealth are on that account feebler supporters of the League of Nations.

Practical Chemistry.

(1) *Introduction to Qualitative Chemical Analysis.* By Th. W. Fresenius. Seventeenth edition. Translated by C. Ainsworth Mitchell. Pp. xx+954. (London: J. and A. Churchill, 1921.) 36*s.* net.

(2) *A Text-book of Practical Chemistry.* By G. F. Hood and Major J. A. Carpenter. Pp. xii+527. (London: J. and A. Churchill, 1921.) 21*s.* net.

(3) *Public Health Chemical Analysis.* By R. C. Frederick and Dr. A. Forster. Pp. viii+305. (London: Constable and Co., Ltd., 1920.) 21*s.* net.

(1) THE treatises on chemical analysis—qualitative and quantitative—planned so far back as 1840 by C. Remigius Fresenius,

the original proprietor and director of the well-known Wiesbaden laboratory, have enjoyed an almost unchallenged position in Germany as standard works for more than three-quarters of a century. During that period they have been frequently revised and reprinted. English editions of these works have been published by the firm of J. and A. Churchill at various times, and are, of course, well known in this country and in America, but have never acquired the same popularity as in Germany. Manuals of chemical analysis written by English and American authors have been found more suitable for class and laboratory instruction. Chemical analysis is, of course, an art which can be acquired only by practice, and a book on the subject should be substantially a *vade-mecum,* which is defined to be anything, especially a book or manual, a person carries with him for daily use. Now this is precisely what the works of Fresenius are not. They have grown so unwieldy that it is impossible to use them as manuals or as the constant companion of the student on the laboratory bench. They are to be regarded rather as works of reference to be consulted in the college library, in which the learner may hope to find an account, more or less detailed, of everything connected with the subject, arranged systematically, and with bibliographical references to the original sources of information.

Mr. Mitchell's book is a translation of the seventeenth edition of the original work brought up to date and made to conform with modern conceptions by Dr. Th. Wilhelm Fresenius. In its English dress it is a portly octavo volume of nearly 1000 pages, and is, in effect, a text-book on general chemistry with special reference to qualitative analysis. Presumably, in its present form, it is primarily intended to supplement the course of lectures given in the Wiesbaden school. It has been translated into English with meticulous care, and so preserves certain blemishes which are characteristic of the original. Practically all the bibliographical references are to German periodicals, and largely to Fresenius's *Zeitschrift für analytische Chemie.* German names, of course, preponderate. English, French, and American chemists have made notable contributions to analytical chemistry, but their names are conspicuous by their absence. Mr. Mitchell is the editor of the *Analyst,* and he must have been struck by the entire omission of any reference to that journal, which now extends to forty-six volumes. Surely in this mass of analytical literature there must be an occasional grain of wheat that might have been allowed to germinate in a foreign soil. We do not know if the English editor was in any way restricted, but in preparing the translation for English-speaking peoples it was, we think, desirable that he should conform to generally accepted English nomenclature and terminology. When the International Committee on Atomic Weights was created, one of its earliest duties was to unify the nomenclature of the elements. Not only were the atomic weights to be made uniform throughout the various nations which were represented on the Committee, but also the names and symbols of corresponding elements. The general principle suggested was that the original name should be retained. This recommendation, although adopted by the American, French, and English representatives, was systematically ignored by their German colleagues. Glucinum, which was discovered by Vauquelin, was still called beryllium, apparently for no other reason than that Klaproth had so termed it. Columbium was first detected and so named by Hatchett in 1801, but this element is invariably called niobium by the Germans, because Rose in 1844 had inferred the presence of a new element, which he had thus named, in the columbites of Bodenmais. It was afterwards found that Rose's supposed new element had no existence; but, as the name "niobium" had been introduced into German chemical literature, it was applied to Hatchett's columbium, discovered more than forty years previously. We think, therefore, in the light of these facts, Mr. Mitchell would have been well advised to conform to English, French, and American procedure.

The book is free from typographical errors, and has evidently been carefully read. There are, however, a few errata which are duly noted; but that the atomic weight of titanium should be 48·1 instead of 40·1 (p. 197) is not one of them.

(2) Messrs. Hood and Carpenter's "Text-book of Practical Chemistry" is claimed by its authors to be "a whole-hearted attempt . . . to indicate the *best methods* of doing everything." Whatever may be thought of the claim, the book, in plan and execution, is in striking contrast with that just noticed. Whereas that work is specially, and almost exclusively, directed to the subject of qualitative analysis, the present authors seek to cover the whole domain of practical chemistry—inorganic and organic preparations, inorganic and organic qualitative and quantitative analysis by gravimetric, electrolytic, and volumetric methods, including gas analysis—within the compass of half the number of pages to which the work of Fresenius extends.

Although the book and its arrangement are,

apparently, largely based upon the experience of the authors as science teachers in schools, it is presumably intended for a higher grade of instruction than that usually given to schoolboys. Indeed, the authors, at times, think it unnecessary to mention certain elementary matters, for the reason that they are probably already known to beginners. They have, however, not been very consistent in this respect. Very elementary things are occasionally treated at considerable length, and space is thereby sacrificed to comparatively unimportant subjects which might well have been devoted to fuller details of more advanced or more difficult matters. The work, in fact, suffers from a lack of a sense of proportion; it bears marks of haste in preparation, as if the authors had not thought out with sufficient care the details of their scheme. The general plan of the work is excellent, but it would be quite impossible for any student, however hard-working, to overtake the whole within the period usually allotted to his training. The time given to the preparation of substances, if he is expected to make any considerable proportion of those enumerated, would alone consume a large fraction of it.

Under the direction of a capable teacher the book is calculated to be of service, if judiciously used, as a laboratory manual. Anyone who had worked through it, with due attention to its directions, would be well equipped with a knowledge and experience of operative chemistry.

(3) The little work on "Public Health Chemical Analysis," by Mr. R. C. Frederick and Dr. Aquila Forster, is apparently designed for the use of the Medical Officer of Health who may be called upon to make analytical inquiries, or may desire to inform himself of the methods employed by the Public Analyst in connection with matters with which he is directly concerned. After a somewhat bald introduction on the general principles of gravimetric and volumetric analysis, the book deals with such subjects as the chemical examination of air, water, sewage, trade waste, and effluents; the analysis of ordinary foods, such as milk and milk-products, flour, bread, sugars, jams, confectionery, proprietary foods, alcoholic liquors, tea, coffee, cocoa, and condiments; the detection of metallic poisons in foodstuffs; disinfectants; soap; rag flock, etc. The methods described are those in common use by analysts, and present no features of novelty. They may be accepted as trustworthy, and well within the competence of an officer who may only occasionally be required to undertake them. The book is well printed, adequately illustrated, and provided with a good index.

The Nature of Man.

The Origin of Man and of his Superstitions. By Carveth Read. Pp. xii + 350. (Cambridge: At the University Press, 1920.) 18s. net.

ONE of the legacies left by the Darwinian controversy has been an intense interest in the highly speculative questions centring round the transition that took place from our semi-human to our human ancestry. The subject has an intense fascination for many, and they will find ample room for the exercise of their imagination while reading the mass of material brought together by the author in support of his hypothesis. He assumes that our early ancestors were large anthropoid apes which took to hunting and a more carnivorous diet, and thus changed profoundly their "former, peaceable, frugivorous habit." Thus there was a selection of those qualities most effective for hunting game. Some of the Primates used unwrought weapons, co-operated in defence, and could communicate with each other—*e.g.* the early hunters went in packs, and thus resembled wolves; indeed, man "became at first a sort of wolf-ape."

In the course of his reflections upon the nature of man the author concludes that "man, in character, is more like a wolf or dog than he is like any other animal." Hence "the Nordic sub-race [of the Mediterranean, we may suppose], with its fair hair, . . . has the appearance of an Arctic beast of prey, like the polar bear." The adoption of a hunting life had many consequences: each pack had its own hunting ground; hence the idea of property; co-operative hunting increased intelligence. The "constructive impulse" thereby became an "absorbing passion," and the use of language was stimulated. The first wars, probably, were waged for hunting grounds; thus the more "virile" and compact of the "wolf-ape" packs predominated, and presumably led to that triumph of Nature, the "Arctic beast of prey"—the Nordic sub-race. Sports and games have been stimulated by the hunting life. Further, "I offer the suggestion that the origin of laughter and the enjoyment of broad humour . . . may be traced to . . . occasions of riotous exhilaration and licence" following on a successful hunt. Hunting life does not explain, says the author, the origin of magnanimity, friendliness, etc.

Mr. Read then turns to the origins of beliefs.

"Savages of the lowest culture have few beliefs that can be called positively injurious. . . . Taboos do more good by protecting person, property, and custom than they do harm by restricting the use of foods. . . . Many rites and observances are sanitary. Totemism rarely does any harm, and

may once have symbolised usefully the unity of social groups. Totemic and magical dances give excellent physical training, promote the spirit of co-operation, are a sort of drill . . ."

The hunting pack fell to pieces owing to a variety of causes, but the situation was saved by the rise of magic—due to a "belief in mysterious forces and from confusing coincidence with causation"—and the magician or wizard, who kept the group together by his power to "make the boldest tribesmen quail." This process of consolidation was helped on by the growth of animism—"a confusion between dreams and objective experience"—and the strengthening of the power of ruling families. The rest of the book is occupied with a discussion on more or less conventional lines of the origins of belief. The author examines the various theories of Frazer, Tylor, Lang, and others, but it is not easy to see where lies the real connection between this and the opening parts of the book.

It is difficult to express an opinion in a few words on an argument which deals with matters mainly beyond our ken. Discussions can scarcely be termed "scientific" that begin with wholly hypothetical stages of society such as the hunting pack of "wolf-apes." The author evidently has not studied the actual facts concerning hunters, or he would have seen that his theory breaks down for the reason that existing hunting peoples approximate more closely to the higher anthropoid apes than to his hypothetical wolf-apes. Moreover, what evidence has he that early man was warlike, or that he went about in packs?

The book has several misprints: p. v., 1805 for 1905; p. 296, Puranas for Punan, Boschmans for Bushmen; p. 61, Battus, ? Battas of Sumatra. The author is also given to repetition—*e.g.* on pp. 2, 28, and 32 he tells us that anthropoids "occasionally eat birds' eggs and young birds; the gorilla has been said to eat small mammals."

W. J. Perry.

Principles and Practice of Psychotherapy.

Psychology and Psychotherapy. By Dr. W. Brown. With a Foreword by Dr. W. A. Turner. Pp. xi+196. (London: Edward Arnold, 1921.) 8*s*. 6*d*. net.

INTO this small book Dr. W. Brown has succeeded in packing a great deal of information on a subject which is now attracting widespread attention. In his preface he enters a timely warning, which is supported by Dr. W. A. Turner in his foreword, that an essential pre-requisite for the practice of psychotherapy is a sound knowledge of general medicine, and particularly of neurology and psychiatry.

Dr. Brown has attempted to crowd so much into such a small compass that rather abrupt changes of theme somewhat interfere with the progressive development of a guiding line of thought. The early chapters discuss in a lucid manner the mechanism of dissociation and repression, which introduces us to the conception of the unconscious and the interpretation of dreams. Much consideration is devoted to the views of Freud, and Dr. Brown indicates clearly where and why he cannot altogether accept them. The section dealing with emotions is rather scanty for so important a subject, and here, perhaps, Freud's views are too summarily dismissed. A special section is allotted to the psychoneuroses of war; the great value of this contribution lies in the fact that Dr. Brown had unsurpassed opportunities for studying both the very early cases immediately behind the line in France, and later the more chronic cases which were met with in the special neurological hospitals at home. This twofold experience enables him to point out certain differences in type and to emphasise the great importance of early treatment in mental disturbances.

Dr. Brown has already published, in various medical journals, many articles dealing with his views on the principles underlying psychotherapy, and in this volume he seeks to crystallise them. He considers that there are four relatively independent factors at work, namely, psychocatharsis or abreaction, psychosynthesis or reassociation, autognosis or self-knowledge, and finally the personal influence of the physician. On the first of these factors he lays great stress, but indicates that the essential aim of them all is self-knowledge. He seems to have coined the term "autognosis" to designate a therapeutic process consisting of a small amount of mental exploration combined with a great deal of explanation and persuasion. Certainly no Freudian would allow that it is in any way comparable to a psychoanalysis.

The last section of the book is a most interesting little discourse on that bugbear of philosophy, the interrelationship of body and mind. Though he does not definitely commit himself, it would appear that Dr. Brown leans more to the theory of Bergson as unfolded in "Matter and Memory" than to any of the alternatives. He makes no mention of the more recent thoroughly monistic system of Kempf.

It is, however, not a little surprising to find that Dr. Brown refers to telepathy in terms which would imply that it is no longer a debatable

theme, and uses it conveniently as a possible explanation of certain obscure phenomena which require a great deal of further investigation.

Apart from the few criticisms which we have made, the book gives an admirable elementary presentation of its subject-matter, and may confidently be recommended to every student of psychology. ALFRED CARVER.

Torres Strait and its Echinoderms.

Department of Marine Biology of the Carnegie Institution of Washington. Vol. x., *The Echinoderm Fauna of Torres Strait.* By Hubert Lyman Clark. (Publication No. 214.) Pp. viii + 223 + 38 plates. (Washington, D.C.: The Carnegie Institution of Washington, 1921.) 15.50 dollars.

ONE result of an expedition to Torres Strait organised by the Carnegie Institution of Washington in 1913 has been that the department of marine biology of that institution has published an admirable memoir on the Echinoderm fauna by Dr. H. Lyman Clark. The 240 species there found are critically examined, as well as fifty species from adjacent regions. Notes on the habitat and habits are furnished in many cases. Forty-one new species were discovered, and some are here described for the first time; many of these and others are illustrated by photographs, and a number are represented in their natural colours from drawings by Mr. E. M. Grosse, of Sydney, on nineteen exquisite plates lithographed by Mr. H. S. Burton at the Government Printing Office of New South Wales. The technical and artistic skill here displayed do justice to the extreme beauty of the objects.

The chief interest of the memoir lies in the light that Dr. Clark's careful analysis of the Echinoderm assemblage sheds on the geographical changes which led to the formation of Torres Strait. C. Hedley's hypothesis of a Queensland gulf in Mesozoic times receives no support from the echinoderms. What may be called the original echinoderm fauna was, in Dr. Clark's opinion, on the north-west side of the present continent, and was of East Indian origin and Indo-Pacific composition. On the other hand, confirmation is afforded for Hedley's view that, as land areas east of New Guinea subsided, the Coral sea became connected with the Pacific; its western shores also receded until the Great Barrier Reef was formed. This sea was invaded by echinoderms from the Pacific, and these now compose the distinctive fauna of the Barrier Reef and the Murray Islands, and to some extent that of southern Queensland and New South Wales. Continued subsidence on both sides led at last to the formation of Torres Strait, and the East Indian echinoderms then migrated eastward and southward to the Queensland coast and Barrier Reef, where they mingled with the Pacific immigrants. The latter, however, have not passed westwards through the Strait.

The echinoderms on which these conclusions are based, though representing all the living classes, are confined to those from shore-waters, and the argument postulates that their migration must follow the shifting of the coasts, and cannot be greatly affected by the dispersal of pelagic larvæ through currents. The actual facts of the distribution are certainly more consistent with this assumption than with the opposite opinion of Mr. Jeffrey Bell. Dr. Clark has used, and used with masterly skill, the facts at his disposal; but over and over again he has to deplore the incompleteness of our knowledge. Some areas are still untouched by the collector; for instance, the Gulf of Carpentaria, in the very heart of the region under discussion, and the southern coast of New Guinea just to the north of it. From other important areas we have but the chance dredgings of a few cruises, and even where a more careful search has been made it has been restricted to a brief period; of the seasonal changes nothing is known beyond the fact of their occurrence. What rich harvest may follow from more extended exploration and more intensive study of selected areas is abundantly indicated by Dr. Clark's learned and suggestive survey.

F. A. B.

Our Bookshelf.

From the Unconscious to the Conscious. By Gustave Geley. Translated by Stanley de Brath. Pp. xxviii + 328. (London: William Collins, Sons, and Co., Ltd., 1920.) 17s. 6d. net.

THERE is a well-known fact of biology called the histolysis of the insect, which was first investigated by Weissmann in 1864. When the insect has completed its larval stage and enters into the pupal stage, its tissues disappear, leaving none of their former cellular elements; all are converted into an apparently homogeneous mass, out of which the imago is generated *de novo*.

There is a lady, known in mediumistic circles as "Eva," of rather unprepossessing appearance, to judge by her photographs, who possesses a power of what is called materialisation. She is by no means unique in the possession of this faculty, but she has been trained, we are told, to give the most perfect exhibition of it which has yet been known. At great personal discomfort, often apparently involving actual pain, under the

conditions of hypnotic trance and in a specially contrived darkened cabinet, she is said to exude, chiefly from the natural orifices of her body, a plastic, amorphous substance which assumes (as Hamlet said of his father's ghost) a questionable shape, usually a face or a hand. The shape is three-dimensional, and the author of this book, who has studied the case at first hand and under his own conditions in his own laboratory, tells us that he has himself touched it and even felt the bones beneath its skin. The exuded substance, notwithstanding its assumption of this solid shape, is invariably, and generally expeditiously, re-absorbed by the lady, and the suggestion is that it could not be detached or amputated without serious, if not fatal, injury to the lady.

The theory expounded in this book is that these two phenomena, the histolysis of the insect and the materialisation of the lady, are fundamentally and essentially identical, and the study of them has led the author to formulate a new principle, which he names dynamo-psychism. This, he claims, is a scientific principle which finally solves all the problems of life and evolution. As a philosophy it has had, he tells us, its forerunners in Schopenhauer's theory of will and in von Hartmann's theory of the unconscious; but the great merit which is claimed for the new formulation is its overcoming of the pessimism inherent in those theories. H. W. C.

(1) *The Copernicus of Antiquity (Aristarchus of Samos).* By Sir Thomas Heath. (Pioneers of Progress. Men of Science.) Pp. v+59. (London: S.P.C.K.; New York: The Macmillan Co., 1920.) 2*s.* 6*d.* net.

(2) *Kepler.* By W. W. Bryant. (Pioneers of Progress. Men of Science.) Pp. 62. (London: S.P.C.K.; New York: The Macmillan Co., 1920.) 2*s.*

(1) THE first of these two little books is the work of a master-hand. Sir Thomas Heath published in 1913 a valuable edition of the only extant writing of Aristarchus, preceded by an introduction of more than 300 pages, in which he gave a critical history of Greek cosmology up to the time of Aristarchus. In the present little book he also begins by giving a rapid sketch of the various systems of the world proposed by Greek philosophers. The statements of ancient writers are next quoted, proving beyond dispute that Aristarchus really put forward the heliocentric hypothesis. We could have wished that it had been shown in more detail how Aristarchus may have been led to propose this way of "saving the phenomena." Lastly, there is an account of the contents of the treatise of Aristarchus on the sizes and distances of the sun and moon, which is of considerable mathematical interest.

(2) Mr. Bryant's account of Kepler's life and work, though very readable, is not altogether satisfactory. The description of how the first two laws of Kepler were found is not clearly expressed and is incorrect in many details. When alluding to Kepler's ideas on gravity it should have been pointed out that his force was tangential to the orbit and not directed to the sun. Of the work on the harmony of the world we are told that "the fifth book contains a great deal of nonsense." That Kepler distinctly states that the harmony is only a mathematical conception, and that there is not really any music of the spheres, is not mentioned. The portrait given as a frontispiece is not of Kepler.

Cocoa and Chocolate: Their Chemistry and Manufacture. By R. Whymper. Second edition, revised and enlarged. Pp. xxi+568+xv plates. (London: J. and A. Churchill, 1921.) 42*s.* net.

THE first edition of this book appeared in 1912, and quickly established for itself a reputation as a useful book of reference, especially in connection with the problems of cocoa and chocolate manufacture, as distinct from those of cacao cultivation and preparation. The second edition has been largely rewritten and brought up to date—a considerable task in view of the important changes which have taken place in cacao production and chocolate manufacture since 1912.

The book is divided into three parts: (1) the history, botany, and agriculture of cacao; (2) the manufacture of chocolates and cocoa powders; and (3) the chemistry of cacao and its products. The few defects of the first edition were nearly all in part 1, and have been remedied, so that the book is now a reasonably complete account of the whole industry. It is well produced, and is provided with a good index and numerous carefully selected illustrations. Presenting, as it does, a broad survey of the whole subject, it should be particularly useful at the present time, when chocolate manufacture, at any rate in this country, is at a somewhat critical period in its history.

Mathematical Papers for Admission into the Royal Military Academy and the Royal Military College and Papers in Elementary Engineering for Naval Cadetships and Royal Air Force for the Years 1911–1920. Edited by R. M. Milne. (London: Macmillan and Co., Ltd., 1921.) 10*s.* 6*d.*

ALL the papers described in the title which have been set during the last ten years are here collected in a single convenient volume. The answers to the questions, where necessary, have been provided by the editor at the end of the book. To those who are engaged in preparing candidates for Army examinations this publication will be extremely useful.

Scurvy: Past and Present. By Prof. Alfred F. Hess. Pp. vii+279. (Philadelphia and London: J. B. Lippincott Co., 1920.) 18*s.* net.

PROF. HESS gives in this work the results of an exhaustive study of scurvy in all its aspects—its history, pathology, causation, symptomatology, diagnosis, and treatment. The bibliography is most complete. The work is very convincing.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The "Flight" of Flying-fish.

HAVING read with interest the letters by Prof. Wood-Jones and Mr. Julian S. Huxley in NATURE for April 21 and 28 respectively, I send some observations of my own which seem to have a bearing on this subject. In the early 'nineties I was engaged in the development of the meteorological kite of the Hargrave pattern, which was adopted at the Blue Hill Observatory for lifting self-recording apparatus in the air, and later adopted by the various bureaus of the world for aerological research. This work brought me in contact with the early pioneer workers on the problem of flight in the United States—Langley, Chanute, the Wrights, Cabbot, Means, Millet, and others—and I occasionally co-operated in experiments on the lifting and driving powers of various devices. One of these was a device in which a stiff rod had attached to one end a flexible rod of bamboo, one end of the bamboo strip being tied near the end of the rigid rod and the other about one-fourth of the way down, so that the bamboo rod formed a loop, over which was drawn a covering of cloth. Now, if one took the free end of the rigid rod and waved the end containing the bamboo loop up and down, he was immediately turned round by a forward motion of the outer end of the rigid rod. The reason of this clearly was that when he lifted the rigid rod upward the flexible loop bent downward, and there was a component of air pressure forward, while when he moved the rigid rod downward the flexible loop bent upward, and there was still a component of air pressure forward. When vibrating the rod up and down there was a persistent forward thrust, and this thrust was so great when the vibration was rapid that the operator was turned completely around in his tracks as on a pivot.

In 1905 I was in charge of the Tieserenc de Bort and Rotch Expedition for exploring the atmosphere with balloons and kites over the tropical part of the Atlantic. The *Otaria*, on which we travelled, was a small boat not much more than 100 ft. in length, with the decks near the water, so that I had an excellent opportunity of studying the movements of flying-fish, which we saw in great numbers.

As these fish left the water the powerful lateral strokes of the tail which lifted them into the air could be plainly seen. As they rose into the air the pectoral fins vibrated with great rapidity, and my earlier experiments with the rod and flexible web led me to believe that exactly this same principle was used by the flying-fish to drive itself forward. The forward part of the pectoral fin is rigid and the rear flexible, so that its rapid vibration gives a strong propelling force. When the fish had gained velocity and the rising impulse given by the tail had culminated, the fins ceased to vibrate and were used as aeroplanes, on which it glided forward, slowly sinking until its tail touched the water, when another lateral stroke lifted it into the air and the process was repeated. In this way the fish could remain in the air for long flights when necessary. The only way in which the motion differs from the flight of birds is that the vibration of the fins probably gives no lifting force, but only a forward driving force, and the fish needs to depend on the tail-strokes for the lift. Had the fish developed a concave under-surface of the fin it could probably have obtained both lifting and propelling force from the fins. H. H. CLAYTON.

June 20.

The Colours of Breathed-on Plates.

THE phenomena of breath-figures on glass are of considerable interest, and have been written upon in the columns of NATURE by the late Lord Rayleigh, Dr. John Aitken, and others. One specially interesting aspect of the subject to which I have recently devoted some attention is the explanation of the beautiful optical effects exhibited by breathed-on plates of glass. If a clean, cold plate of glass is lightly breathed on and then held in front of the eye, and if a small distant source of light is viewed through it, coloured haloes will be seen surrounding the source. The characteristic feature of the halo exhibited by a moderately heavy (but not too heavy) deposit is that the outermost ring in it is achromatic, with a reddish or brown inner margin, followed inside by a succession of rings of various colours. As the film of moisture evaporates, the halo contracts and the coloured rings move inwards, ultimately disappearing at the centre of the halo. The entire halo presents a radiating fibrous structure.

The explanation of these phenomena presents some difficulties. One is tempted to suppose (as, indeed, Donlé and Exner have already) either that the minute droplets of water condensed on the plate which diffract the light are of approximately equal size or that they are arranged at more or less constant distances from each other. A microscopic examination of the condensed film shows, however, that neither of these suppositions is anywhere near the truth. The size of the individual droplets shows a variation of several hundred per cent., and their arrangement in the film is entirely irregular, being determined presumably by the presence of invisible condensation nuclei on the surface of the plate —a view that is strongly supported by the fact that successive deposits on the plate are seen under the microscope to preserve the same configuration with a surprising degree of accuracy. Further, if the size of the droplets were the determining factor in the production of the diffraction haloes, it would be difficult to understand why as they evaporate the rings in the halo should *contract* in size.

These facts necessitate an entirely different supposition regarding the element of regularity in the film which enables it to give rise to a recognisable system of coloured diffraction haloes. Measurements I have made seem to show that the droplets in the film—whether large or small—have practically all the same angle of contact with the surface of the plate, this angle of contact diminishing as the film evaporates. The formation of the coloured haloes is, on this view, due to the passage of the light *through* the minute lens-shaped droplets; the maximum deviation of the light determined by the common angle of contact fixes the position of the outermost achromatic halo, and the colour-sequence following within it would be practically the same for all the droplets irrespective of their size. This would also furnish a satisfactory explanation of the contraction of the halo as the film evaporates. C. V. RAMAN.

Mutations and Evolution.

THE article on my recent little book on "Mutations and Evolution" in NATURE of July 14, p. 636, shows such insight in the exposition of some of the views

there set forth that it may seem ungrateful of me to venture to reply to anything the reviewer has written. Nevertheless, there is one important point in which I feel that my argument has been missed. My conceptions of the relation between recapitulatory and mutational characters are not easy to state clearly in a brief space, and I am willing to admit obscurity in certain passages, as evidenced by your reviewer's failure to grasp my meaning, but I am not willing to plead guilty to the more serious charge of obscurantism.

The argument was not that mutations are limited in their scope by the existence of non-cellular structures in organisms, but rather that embryonic characters which show recapitulation, and at the same time imply re-adaptation of the organism, cannot have arisen by chance mutations in the germ-plasm, but must have arisen as environmentally induced responses which could become germinal only according to the principle of the inheritance of acquired characters.

By general agreement mutations arise as such in the germ-plasm, *i.e.* probably in the chromosomes. But there is another possible route into the germ-plasm, namely, *via* a modified soma (probably in its beginning a modified cytoplasm), ultimately affecting the germ-nuclei.

Orthogenetic changes I placed in a third category as showing recapitulation and yet arising in the germ-plasm, since they are non-adaptational, and hence probably not environmentally impressed on the organism. The relations between these three types of characters are admittedly obscure, but it does not follow that they are non-existent or that the conceptions regarding them are obscurantist. I wished particularly to contrast mutations and embryonic recapitulatory characters from the point of view of organic structure, indicating that the principles which will explain the one cannot adequately explain the other. R. Ruggles Gates.

King's College, Strand.

Prof. Gates's restatement of certain points in his original argument, if more explicit, nevertheless meets but one of the issues raised in my article. In answer to the doubt therein expressed as to whether he himself can be held blameless of the offence with which he charges others, he pleads "not guilty." But if "obscurantism" (the author's word, not mine) be judged too harsh a verdict on the passage cited, *obscurum per obscurius* in respect of this particular statement—and others—is not to be gainsaid. And shall we even then acquit the author on the more serious count? Or will the general reader desirous of comprehending the relation of Mendelian to Darwinian theory uphold the charge after perusal of the author's introduction? If he do not, he will unquestionably deserve the encomium which the author, so disarmingly, bestows upon myself.

The Writer of the Article.

Molluscan Fauna of Scottish Lakes, and a Pisidium New to the British Isles.

May I through the columns of Nature invite the assistance of naturalists who may be visiting Scottish lakes and tarns on their holidays in making known the molluscan contents?

Whilst Mr. R. A. Phillips and Mr. Stelfox have investigated the mollusca of the Irish lakes, and Mr. C. Oldham those of much of Wales and England, our knowledge of the Scottish fauna is lamentably deficient. If living specimens are unobtainable, dead shells from the shores will be acceptable as showing what species are present. In either case, for purposes of identification, no special method of preservation is necessary—the specimens will travel perfectly if packed in sand or sawdust; but if spirit is procurable fresh specimens would be more useful if placed in that medium. In all cases, of course, locality and date are essential.

As instancing the interest attaching to the investigation, and the possibility of further important discoveries, I may mention that Dr. Nils Hj. Odhner, of the Rijksmuseum, Stockholm, has just identified some specimens from Loch Ness, in my collection, as being *Pisidium clessini*, Surbeck, a deep, cold-water species known also from Sweden and Switzerland, which he has also recognised from two other British localities. Cup and Ring Markings.

In reply to Mr. Abbott's letter in Nature of July 21, p. 652, I regret that he did not see the photographs to which I referred; had he done so he would have appreciated the difference between these and his own. As there is no tangible evidence that such reconstructed surfaces are due either to gelic selection or adsorptive precipitation, I submit that, pending the proving of the gel theory, it is safer to describe the process as "concretionary," for this term covers much ignorance, and is, at least, non-committal.

May I say that the ridged mortar, as shown in Mr. Abbott's interesting photograph, is not found only on the northern sides of buildings near the sea; I have excellent examples from Corfe Castle and other buildings in the district, from old field-walls at Kirkby Lonsdale, and from many other places inland?

There is a coign of calcareous sandstone in the wall of an old barn a few miles from Kirkby Lonsdale with the whole surface naturally ridged and ringed, while the mortar surrounding it is unaltered.

I have never suggested that similar patterns were not carved on some rock surfaces by prehistoric man, but that, if they were, these mystic markings were copied from Nature long before the days of mortar!

I regret I am now unable to find the photographs of 1896, but when I do Mr. Abbott shall see them.

C. Carus-Wilson.

Science and Civilisation.

The letter of Mr. Henderson Smith and Major A. G. Church in Nature of July 28, p. 684, is most welcome as showing that scientific workers are at last beginning to realise that it is time for science to make itself felt, not only for the acquisition of knowledge and the improvement of machinery and production, but also for the establishment of a national and harmonious social order.

May I say that a scheme has already been evolved which should appeal to all truly scientific sociologists? It is based essentially on economic and eugenic principles, and is termed Neo-Malthusianism. It aims at eliminating poverty and other social evils by proportioning population to the means of subsistence, and at securing race improvement by maintaining the selective struggle of Darwin, substituting humane voluntary abstention from reproduction for brutal elimination by disease and starvation. It aims also at the elimination of class and international warfare through the diminution of the pressure of population, and at the reduction of vice and disease by promoting universal early marriage.

Anyone interested in this subject is invited to write to the hon. secretary of the Malthusian League, 124 Victoria Street, S.W.1.

C. V. Drysdale.

Remarks on Simple Relativity and the Relative Velocity of Light.

By SIR OLIVER LODGE, F.R.S.

I.

IN continuation of my article in the Relativity Number of NATURE (vol. cvi., p. 795, February 17, 1921), I propose to discuss more fully, and to express as clearly and simply as possible, some of the points on which philosophic disciples or expounders of Einstein have written, so as perhaps to remove a certain amount of misapprehension, and incidentally to set my own views before other physicists, in order that they may be controverted where necessary. On some other points of more general interest I have written in the *Fortnightly Review* for next September, especially on the foundation which had been laid by Einstein's predecessors before the philosophic doctrine of relativity was made definite and erected into a comprehensive physical theory.

The Fundamental Relativity Hypothesis.

Einstein's first fundamental assumption is that direct observation of our absolute motion through space is not only unachieved, but also in the nature of things impossible; wherefore it can be held that such motion has no intelligible meaning. Those who admit an æther prefer not to shut the door on inquiry, but meanwhile express their provisional agreement by saying that its various functions and properties are so uniform, so universal, and so interrelated, that observation of any suspected effect of motion through the æther is liable to be frustrated or negatived by some—so to say—inevitable opposite effect; and that the compensation, at any rate over a wide range, is complete.

Einstein's second fundamental assumption is that the one absolute quantity which *can* be observed, namely, the velocity of light—if it be a velocity—is unique and so fundamental that every observer must necessarily measure the same result if he make his measurements correctly, no matter what his own motion may be; which, after all, is only another way of saying that his own motion through the æther is pragmatically a meaningless expression.

It is not claimed that these assumptions, which are certainly consistent with the Larmor-Lorentz transformation equations—at least, when they include the factor β, expressive of the FitzGerald-Lorentz contraction—are really established by them. That would be reasoning in a circle. Nor do the equations necessarily substantiate any metaphysical assertions about time or space or æther; but they do lead to algebraic and legitimate deductions.

The Time and Space Transformation.

The importance of those transformations—correlating the states of the same material system travelling at different speeds—can scarcely be exaggerated. They have been arrived at in many ways, usually by aid of ideal and hypothetical and apparently impossible experiments, sometimes by considering that an event does not effectively happen until we have seen it happen, thus entailing relative delay; and they have been variously interpreted. The original gist of the equations was that a moving observer must not only take his distances as variable; he must consider his times variable too. He must have a local and fictitious time peculiar to himself, if he is to ignore his own motion and treat his direct measurements as conclusive.

Einstein's step was equivalent to dispensing with any overt fiction about this subjective or local measure of time, to claiming that it was as real as any other, though peculiar to each observer, and to seeing what emerged.

Now if we agree to waive any question of experimental practicability, and proceed in an ideal fashion, it is easy enough to obtain notions about the required transformation; and as I have not seen the equations obtained so directly or naively, I proceed to deduce them thus:—

A stationary observer, supposed able to time the passage of light from a source at a distance x, may be expected to get the result

$$\frac{x}{t}=c.$$

If he be moving towards the source with speed u, he will be relieving the light of some of the journey by doing that bit himself. The light need now only travel a smaller distance x' to meet him, and the observer will have travelled the remainder, namely, $x-x'$. So if the time taken on the jointly performed journey be t', and if he finds it possible to measure the distance x' at the instant the light reaches him, which is evidently the right moment, he will get

$$\frac{x'}{t'}=c \quad \text{as the speed of the light,}$$

and

$$\frac{x-x'}{t'}=u \quad \text{as his own speed.}$$

Given these three equations, we get by mechanical algebra without further reasoning

$$t=t'+\frac{ux'}{c^2},$$

as well as the more obvious

$$x=x'+ut',$$

without mentioning relativity at all.

If all these measurements could be really made, we should have

$$c+u=\frac{x}{t'},$$

and u could be determined in terms of c. But the measurements are impracticable as they stand, for how is an observer to know the instant at which a particular portion of light left the source? In other words, how is he to time an event on the source when he is dependent on the light itself for information of its occurrence? He might have the event telegraphed, but that information also is transmitted by the æther at the same pace. So the foiled inquirer will naturally try to get some additional data by reversing his motion and starting back again from

his present position at distance x', so as to be moving away from the light instead of towards it. The light will now have to catch him up; and he may think, at first, that the ray which left the source at the instant he began his return journey will take the original time t to reach him, since it now has to travel the full distance x. But he will have to travel a little further than the original position, and take a little longer time, before he is overtaken; and he cannot write the reciprocal equations

$$t' = t - \frac{ux}{c^2}$$

and

$$x' = x - ut,$$

because they are inconsistent with the previous ones.

To make the two pairs of equations agree (as relativity demands), either x must equal x', which frustrates the whole experiment, or a common factor must be introduced, say β, such that

$$t' = \beta\left(t - \frac{ux}{c^2}\right), \text{ or } \beta t\left(1 - \frac{u}{c}\right);$$

and

$$t = \beta\left(t' + \frac{ux'}{c^2}\right), \text{ or } \beta t'\left(1 + \frac{u}{c}\right).$$

This will render them harmonious, and a suitable value (the only right value) of β is easily reckoned—again mechanically, without further hypothesis—namely,

$$\beta^2\left(1 - \frac{u^2}{c^2}\right) = 1.$$

If that is satisfied, the reversal of the journey will not give any different result; there is perfect reciprocity. You cannot by an experiment of reversing your motion with regard to light, or reflecting back the light with regard to the observer, discriminate between $c-u$ and $c+u$; nor can you discriminate either from c.

Now this β factor is the FitzGerald-Lorentz contraction; the experiment thus neutralised is the Michelson-Morley experiment; and the direct supposition that an observer must find $c-u$, and c, and $c+u$ all the same, or at least indistinguishable by observation, and that there is nothing more to be said, is the point of view of Einstein.

These names must suffice to suggest a flood of ideas to those who have read about the subject.

To sum up compactly:—

Assume that you cannot help measuring the same speed of light whether you be moving or stationary, so that x/t and x'/t' both equal c (the accented letters referring to the measurements made when you were moving with speed u to meet the light), then allow that x/t' is not equal to $c+u$, as you would expect, nor x'/t equal to $c-u$ (for in that case xx'/tt' would equal c^2-u^2 instead of c^2), but that, instead,

$$\frac{x}{t'} = \beta(c+u) \text{ and } \frac{x'}{t} = \beta(c-u),$$

which, together, require that

$$\beta^2 = \frac{c^2}{c^2-u^2};$$

then all the rest follows.

The Contraction.

A customary and older interpretation of the introduction of the factor β—to complete and make accurate what then became the Larmor-Lorentz transformation—is that the measuring rod with which you are hypothetically supposed to measure x or x' shrinks to $1/\beta$ of its normal length if the experimenter is moving either to or fro with speed u, so that all distances in the direction of motion measure out a little bigger than they otherwise would; more steps of the yard measure having to be taken. Note that space or æther does not shrink, but only the matter in space. The distance x has not changed, but only the instrument with which you hypothetically measure it. That having shrunk, the fixed distance measures out longer. The same thing happens with the instrument whereby you are supposed to measure time. Both distance and time of journey are abbreviated by approach, but, to measurement, not so much as an unchanged measurer would give. They are both lengthened by recession, and the measurements give rather more increment than might have been expected.

The ratio between measurements made during uniform approach, and the same made during relative rest, is

$$\frac{x'}{x} = \frac{t'}{t} = \beta\left(1 - \frac{u}{c}\right) = \sqrt{\left(\frac{c-u}{c+u}\right)}.$$

This line, with the definition $c = x/t$, is the briefest possible summary of the transformation equations.

A short and easy way of getting, or at least of recording, the essence of the transformation is to allow for the contraction of the hypothetical measuring rod by multiplying any distance across space supposed to be measured by a flying observer—flying towards or away from a distant event which really occurred at the instant he started to fly—by an undefined numerical coefficient β, and omitting this factor from any distance which he could have measured at rest before starting.

Thus let an event occur at the origin, and let an observer at x and t immediately begin travelling towards it, so as to meet the light at a place which appears to him to be x' and t', the combined velocity over the original distance being $c+u$, he can correct his x' measurement, which has been traversed by the light alone, and write

$$\frac{x}{c+u} = \frac{\beta x'}{c};$$

while if he started from the leisurely measured x' and t' position, directly the event occurred at the origin, and receded so that the light overtook him at what appears to him to be a place x and t, coming with the relative velocity $c-u$, he can correct his x measurement for the whole distance traversed by the light, and write

$$\frac{x'}{c-u} = \frac{\beta x}{c};$$

saying, if he likes, that it is just the same as if he had stood still and the light had come to him with diminished speed. (Or he might time his own journey as $\frac{\beta x - x'}{u}$, and equate that to $\frac{\beta x}{c}$). Combining these equations with the definition

$$\frac{x'}{t'} = \frac{x}{t} = c,$$

and not troubling about the y and z co-ordinates, which remain unchanged and need no attention, we get the Lorentz transformation complete (and incidentally we see that the usual differential invariant $ds^2 = dx^2 + dy^2 + dz^2 - c^2dt^2$ is always zero for light).

Once the transformations

$$\begin{cases} x' = \beta(x - ut) \\ t' = \beta\left(t - \frac{ux}{c^2}\right) \end{cases} \text{ with their correlative } \begin{cases} x = \beta(x' + ut') \\ t = \beta\left(t' + \frac{ux'}{c^2}\right) \end{cases}$$

are introduced, the coefficient β is self-defined as $\beta^2(c^2 - u^2) = c^2$, and results flow in thick and fast. Thus if we seek to superpose a velocity dx'/dt', or v, on the speed u, and reckon the result as dx/dt, or w, working mechanically on the above two equations, we do not find, as we might expect, $w = u + v$, but

$$w = \frac{u+v}{1 + \frac{uv}{c^2}}.$$

This *appears* to have nothing to do with the β factor, but to depend only on the second term in the expression for t. We must remember, however, that without the β factor we could not write the reciprocal equations, which permit simple reversal of sign in v if it is opposed to u. The consequences of this law of composition of velocities are astonishing, and include among them the uniqueness and maximal character of the velocity c.

Confirmation.

The Einstein assumptions have never been directly ascertained by experiment. They are not the result of experiment at all; they are a reasoned type of hypothesis, and any provisional confirmation must be derived from the legitimacy of the conclusions which, from them and their extensions, the far-reaching genius of Einstein has shown to be attainable. Briefly we may cite the general type of confirmations, including those of his completer theory, thus:—

The velocity of light inside transparent matter, being less than its value in free space, is affected by its motion in the way Fresnel predicted and Fizeau confirmed. The equations give this result without the need of Fresnel's theory.

Even outside great masses of matter the velocity is now discovered to be slightly affected (still diminished, never increased) in a second-order way that Einstein predicted and astronomers confirmed. Starlight is deflected by this gravitational refractivity.

Not only so. The neighbourhood of a very large mass of matter introduces secondary higher-order effects into the æther in such a way as to affect not its luminiferous properties only, but its gravitational structure too; and the consequence is that the orbit of a planet sufficiently near the sun behaves, not exactly in accordance with the laws of particle dynamics in empty space, but with a slight modification, depending on the squares of small quantities, such as the general principle of relativity enabled Einstein to calculate. And, as everyone knows, an outstanding discrepancy—though one detected only through the extreme refinement of astronomy—was thus triumphantly removed from the planet Mercury, the only planet near enough to the sun to be sensibly affected.

Thus, then, the general mathematical trend of ideas on which the principle was founded may be claimed as confirmed in this *ex post facto* manner; but many varieties of expression, and attempts to interpret the principle philosophically, are far from establishment still.

Alternative Modes of Statement.

If we take up an agnostic position, we cannot say—and Prof. Einstein seems to agree—that, as a deduction from experiment, any philosophic or metaphysical position is really proven. What we can definitely say is that certain statements are consistent with all the experiments hitherto made, but we cannot say that every other mode of statement is ruled out. In nearly every case—probably in every case—the result of experiment can be expressed otherwise. Thus, for instance, my experiment with the rotating discs (Phil. Trans., vol. clxxxiv., 1893) showed that their motion neither added nor subtracted anything, nor affected the velocity of light in their immediate neighbourhood, although their circumference was travelling at a speed almost sufficient to tear the steel asunder, and although an exceedingly minute alteration in the speed of light could have been observed; but this negative result can be expounded, and indeed was expounded, by saying that the æther—the vehicle of light—is not carried forward or perturbed at all by the adjacent moving matter. And that is part of an entirely rational æther theory of the atomic structure of matter.

The famous Michelson-Morley experiment, again, wherein no result is found, although the apparatus *must* be immersed in a relative æther stream, can be, and was, explained by saying that every solid body suffers a FitzGerald-Lorentz deformation due to its motion relative to that stream.

Again, the most important Fizeau experiment, one which did yield a positive result, because here light was travelling through and inside transparent moving matter, and so was accelerated and retarded by a measurable amount—not, indeed, beyond the velocity c, but beyond the velocity c/n, where n is the index of refraction—this result was explained, and by Fresnel anticipated, by assuming (crudely) that a given proportion of the æther clung to moving matter and was transported with it, or (less crudely) that the presence of matter so modified or loaded the æther as not only to retard the light considerably in any case, but to retard it differently when in motion than when at rest. Electrically, this comes out with complete clarity, because the loading property—the matter-caused modification of the æther constants μ and K—really does belong to the matter, and travels with it.

So in every instance which had been already explored an explanation was forthcoming, and had been accepted as sufficiently plausible and satisfactory; but it was a different explanation in each case. Not differing so as to be inconsistent—they were all consistent with a certain view of

the æther, and were all in agreement with the electrical theory of matter—but still, when Einstein showed that the law of composition of velocities appropriate to his principle of relativity accounted for them all as an immediate corollary, without effort and without any assumption beyond what was embodied in that principle—this feature of directness naturally aroused the keen attention of physicists.

(Discussion of the relative velocity of light is deferred to next week.)

(*To be continued.*)

Endowment of Scientific Research in the United States.[1]

IN NATURE for May 29, 1919, an account was given of the organisation of the National Research Council of the United States of America. Supported during the war largely by the Government, but now entirely by private bodies and firms (it has lately received a grant of 5,000,000 dollars from the Carnegie Corporation), this body owes its existence to a trend of opinion by no means confined to the capitalist classes which maintain it. The American Federation of Labour explicitly and emphatically professed its belief in the fundamental importance and beneficent results of scientific research—more especially research in pure science—in a manifesto quoted in the Report for 1918–19 of our own Department of Scientific and Industrial Research. This unanimity on the part of employer and employed in their recognition of the importance for the development of American industries of the promotion of research gives additional weight to the imposing array of facts and figures assembled by the National Research Council in the bulletin under notice, which deals with funds, other than Federal and State funds, available in 1920 for this purpose.

In the preparation of the following summary it has been assumed that where the total endowment, but not the amount annually available, is given in the bulletin, 5 per cent. of this total was available. In some cases no information is given as to the amount of the fund—either capital or interest—and these were necessarily omitted in compiling the money totals. The columns A, F, U give the number and aggregate annual value in *thousands of dollars* of the funds provided by, or in connection with :—A : academies, associations, societies, and museums; F : foundations, hospitals, and research institutes; U : universities and colleges.

	A		F		U	
	No.	1000 dols.	No.	1000 dols.	No.	1000 dols.
I. Medals and prizes	65	19	1	—	24	20
II. Grants	40	361	8	15,143	66	96
III. Institutional funds	14	255	30	2,322	176	2,056
IV. Fellowships and scholarships ...	6	34	6	120	263	352
Total ...	125	669	45	17,585	529	2,524

The most conspicuous figure in this table is the amount of the grants by foundations, etc., and this is almost entirely composed of appropriations (amounting to 15,000,000 dollars) made by the Rockefeller Foundation, New York City, "partly to agencies which it creates for carrying out specific programmes, and partly to other existing organisations to enable them to carry out specific programmes." Several other important annual appropriations are detailed below.

Source	Amount (1000 dols.)
Rockefeller Institute for Medical Research	1,100
Carnegie Institution of Washington—for research in astronomy, 221; physics, 329; botany, 65; biology, 131; nutrition, 52; eugenics, 31; embryology, 43	872
Carnegie Institution, minor grants ...	117
American Museum of Natural History—for promotion of research, exploration, etc.	278
Harvard Fund for medical research ...	363
J. De Lamar Funds for study and teaching of dietetics and of the origin, etc., of disease	377
John McCormick Institute for Infectious Diseases Research Fund	100
National Research Council fellowships for research in physics and chemistry ...	100
Massachusetts Institute of Technology, general budget appropriation for research	100

Thus, of the aggregate amount of the sums specified in the bulletin—20,778,000 dollars—more than 82 per cent. is attributable to Rockefeller and Carnegie benefactions, and more than 88 per cent. to these and the six other sources specified.

At the recent congress at Oxford of representatives of the universities of the British Empire much emphasis was laid on the fundamental importance of scientific research and on the necessity for providing material aids and training for it. The figures given above constitute a striking commentary on the following observations made by Prof. Joly at the congress: "Perhaps the most striking feature of American universities, as viewed by the British visitor, is the prevalence of research, and the lavish provision made for its prosecution. . . . There is research in everything. The American recognises to the full the value of the mental attitude induced by research, and this recognition is not confined to the university professor, from whom it may be expected, but extends, so far as I could gather, everywhere throughout the States." At some future date the National Research Council will perhaps take stock of the results of the application of these vast sums of money, and may possibly have a tale to tell of misdirected or unfruitful effort; but it can scarcely be doubted that the net results will affect substantially the welfare of mankind—perhaps so

[1] "Funds available in 1920 in the United States of America for the Encouragement of Scientific Research." Bulletin No. 9 of the National Research Council, 1701 Massachusetts Avenue, Washington, D.C., March, 1921. 1 dollar.

substantially as to give a new significance to the phrase "Almighty Dollar," and to affect the sociologist's estimate of the social order which has made possible the accumulation of multi-millionaire fortunes.

In a "Subject Index" the bulletin lists all the funds known to be available for the support or encouragement of research in the biological, mathematical, and physical sciences and their applications, and from this index has been prepared the following table, which, though not exhaustive, serves to indicate the subjects more generally favoured by founders and administrators of funds:—

Subjects	No. of Funds
Agriculture	12
Anthropology	24
Astronomy	33
Biology	36
Botany	13
Chemistry	57
Engineering	32
Geography	16
Geology, etc.	18
Industrial research	47
Medicine	147
Mineralogy	13
Pharmacology	14
Physics	49
Science, unrestricted (including appropriations of the Rockefeller Foundation)	120
Zoology	14

In the list of nine large endowments already given above, the ample provision for medical research is noticeable. Columbia University has a fund for cancer research producing 70,000 dollars per annum, and four other funds produce 291,000 dollars per annum for medical research. Cornell has 45,000 dollars per annum for research in veterinary medicine. Pennsylvania has lately received 500,000 dollars towards a tuberculosis research institute, and Iowa has a Welfare Research Station Fund for investigating "scientific methods of conserving and developing the normal child," for which it appropriates 25,000 dollars per annum.

A few other noteworthy funds may be particularised:—

Anthropology and Natural History.—Bishop Museum of Polynesian Ethnology, etc.: Research funds, 75,000 dollars per annum.

Bio-chemistry.—Leland Stanford Junior Food Research Institute: 700,000 dollars provided by the Carnegie Corporation for its support for ten years.

Engineering and Industrial Research.—United Engineering Societies' Fund, 500,000 dollars (capital). American Society of Heating and Ventilating Engineers: 21,000 dollars per annum for five years. Du Pont de Nemours Company Fellowships for Research in Chemistry in twenty-one universities: 750 dollars each.

Science, unrestricted.—Smithsonian Institution, Washington: Founded 1846, present fund 975,000 dollars. Brooklyn Institute of Arts and Sciences: Fund for research purposes of the museum, 600,000 dollars.

Mention may also be made of two foundations having an international character:—The American Field Service Fellowships for research in French universities: 30,000 dollars per annum; and the American Scandinavian Foundation, providing twenty travelling fellowships of 1000 dollars each.

The publication of this interesting bulletin provokes the question, What similar lists have been published in other countries? Particulars of scholarships, etc., open to graduates are to be found in the "British Empire Universities' Yearbook," and it is understood that in the next edition information regarding other funds available for the encouragement of scientific research will be given; but in the meantime the only published lists comparable with those given in the bulletin are, it is believed, the lists of "Encouragements et Aides Financiers" included in a recently published work by MM. Tassy and Léris called "Les Ressources du Travail Intellectuel en France." The annual value of prizes distributed in France by the national academies and by societies dependent on private initiative is stated to exceed 1,500,000 francs, and an almost equal amount is said to be devoted to subventions to missions, travelling fellowships, and other aids to research.

Obituary.

LORD REAY, formerly Governor of Bombay, and an active worker for intellectual interests in many directions, died on August 1 in his eighty-second year. From a detailed notice in the *Times* we extract the following particulars of his career: Born on December 22, 1839, Lord Reay was educated at the Gymnasium at The Hague and at the University of Leyden, where he graduated in laws. In 1866 he made a tour through the United States for the purpose of studying the social and political condition of the country at a particularly interesting period of reconstruction. On his return to Holland he was elected president of a Society for the Promotion of Manufactures and Handicrafts, and in that capacity he organised the first industrial exhibition which was ever attempted in Holland. In 1871 he was returned to the Chamber of Representatives of the States-

General as Liberal member for Tiel, and again in 1875, the year in which his father succeeded to the Scottish title of Reay, on the death of the ninth baron. In 1877 he resigned his seat in the Dutch Chamber of Representatives, and became naturalised as a British subject. He was created a baron in the peerage of the United Kingdom in 1881, and in 1884 was elected rector of St. Andrews University.

In 1885 Lord Reay was appointed Governor of Bombay, where he brought about an amelioration of the Forest Laws, which gave universal satisfaction to the natives. Foremost among other questions which arose for solution was that of education, a subject which was always of the greatest interest to Lord Reay. His policy was to substitute local control for direct governmental supervision, to establish grants in aid in place of payment by results, and to develop a modern side in secondary schools. Technical education received a great impetus, and a permanent memorial of its development is the Victoria Jubilee Technical Institute for Mechanical Industries at Bombay. His Governorship ended in 1890, and his services to the Presidency were commemorated by the erection of a marble statue in Bombay.

Afterwards, as president of University College, London, of the Institute of International Law, and of the Franco-Scottish Society, and as member of the Senate of London University, Lord Reay found full scope for his energies. He became the first president of the British Academy in 1901, and was president also of the Royal Asiatic Society. On the resignation of the late Lord Londonderry in 1897 Lord Reay was unanimously elected chairman of the London School Board, a post which he retained until the abolition of the Board in 1904.

Mr. William Taylor, of Lhanbryd, who died recently at Elgin, aged seventy-two, was a most active zoologist and geologist, and made many contributions to science. Trained as a pharmaceutical chemist, he emigrated early in the 'seventies to Texas, where in the intervals of business he devoted much attention to the reptiles and small mammals. He corresponded with the British Museum, to which he sent many valuable specimens, accompanied by notes on their mode of life. In 1892 Mr. Taylor returned to Scotland, and henceforth lived in retirement in his native village of Lhanbryd. Here again he studied the mammals, especially the cetaceans stranded on the coast; but his most important work was the collection of fossil reptiles from the Triassic sandstone of Morayshire, and of fossil fishes from the Old Red Sandstone of the same county. Some of his fossils were sent to the Royal Scottish Museum, Edinburgh, where they were described by Dr. Traquair, but the greater part of his collection was acquired by the British Museum, where much of it was described by Dr. G. A. Boulenger and Dr. Smith Woodward. Several new species were named after him. Until 1914 Mr. Taylor made an annual tour to the south as far as London, thus keeping in touch with those who were interested in his researches, and he often attended the meetings of the British Association. He did not write much himself, but was always a keen observer, and gave valuable help to those who published technical accounts of his discoveries. He also did much to spread an interest in natural science in the district in which he lived.

The death is announced of Dr. J. E. Blomfield at Sevenoaks on July 8. Dr. Blomfield was educated at Winchester, and later at the University of Oxford, where he obtained a demyship at Magdalen College in natural science. He afterwards entered the medical course, was elected Radcliffe travelling fellow, and worked at Jena, Vienna, and Paris. His clinical studies were pursued at University College Hospital, where he became house physician. On the advice of friends Dr. Blomfield decided to enter general practice, and from 1889 onwards practised at Sevenoaks. He was an accomplished microscopist, at an early date in his career published a paper on spermatogenesis, which attracted the attention of Charles Darwin, and later made a number of notes on, and preparations of, new growths in trees.

The death is announced, at the age of sixty-one, of Prof. Francis Bacon Crocker, professor of electrical engineering at Columbia University from 1893 to 1914, and president of the American Institute of Electrical Engineers in 1897. Prof. Crocker's work in the standardisation of electrical equipment throughout the world won him high praise from Lord Kelvin. He was the author of books on electric lighting, electric motors, the management of electrical machinery, and related subjects.

Dr. W. E. Stone, whom a cablegram in the daily Press reports to have lost his life in the Assiniboine Mountains while trying to carry his wife up a cliff from which she had fallen, had been president of Purdue University, Indiana, since 1900. He had previously been professor of chemistry in the same institution, and earlier still had been officially employed as a chemist by the States of Massachusetts and Tennessee. He had published reports of numerous researches upon the carbohydrates. Dr. Stone was in his sixtieth year.

We regret to see in the *Times* of August 2 the announcement of the death of Prof. Edmond Perrier, member of the Paris Academy of Sciences and of the Academy of Medicine, and honorary director of the Paris Museum of Natural History.

Notes.

The French Association for the Advancement of Science is meeting this week at Rouen under the presidency of M. Rateau. The scientific proceedings of the association will be carried on in twenty-two sections and sub-sections. There will be two lectures—one on the synthesis of ammonia by M. G. Claude, and the other on aviation of to-day and in the future by M. Bréguet.

The council of the Museums Association has elected Mr. T. Sheppard, of the Municipal Museums, Hull, as president of the association for 1922–23.

Dr. D. Segaller, who has been with the British Dyestuffs Corporation, Ltd., since the firm of Messrs. Read Holliday and Sons was acquired by British Dyes, Ltd., is severing his connection with the Corporation. As head of the technical department he has been in charge of a staff of chemists engaged on research on various problems connected with the activities of the Corporation.

A description of ball lightning seen in the sky at St. John's Wood during a thunderstorm in the early morning of June 26 has recently been received at the Meteorological Office. The phenomenon, a large incandescent mass floating in the air below the clouds and apparently stationary for some minutes, is of great rarity, and the Director of the Meteorological Office, London, S.W.7, would be greatly obliged if persons who observed it on this occasion would communicate with him. Prof. I. Galli has brought together a number of observations of globular lightning recorded in classical literature, as well as many from modern scientific publications, and has described them in several papers issued by the Portificia Accademia dei Nuovi Lincei of Rome.

In consequence of the retirement of Sir Hercules Read, the department of the British Museum hitherto known as the Department of British and Medieval Antiquities and Ethnography has been divided, and the following appointments have been made by the principal trustees:—Mr. O. M. Dalton to be Keeper of the Department of British and Medieval Antiquities; Mr. R. L. Hobson to be Keeper of the Department of Ceramics and Ethnography; Mr. T. A. Joyce to be Deputy-Keeper in the Department of Ceramics and Ethnography. Mr. Reginald Smith, hitherto Deputy-Keeper in the undivided department, becomes Deputy-Keeper in the Department of British and Medieval Antiquities. The prehistoric collections fall into the Department of British and Medieval Antiquities, and the Oriental collections into that of Ceramics and Ethnography.

On Thursday, July 21, a memorial was unveiled in the public gardens at Dartmouth to the memory of Thomas Newcomen, the great pioneer of the steam engine. Newcomen was born in Dartmouth in 1663; he followed the trade of blacksmith there, and was also a Baptist preacher. He appears to have been associated with Thomas Savery in his work on the use of steam, but to Newcomen belongs the credit of developing the cylinder and piston steam engine, the first one being erected near Dudley Castle in 1712. By 1716 similar engines were at work in Staffordshire, Warwickshire, Cornwall, and Flintshire, and the engine had no rival until the time of Watt. One or two Newcomen engines were at work until the beginning of the present century. During the latter part of his life Newcomen lived in London, and he died there on August 5, 1729. He was buried in the Bunhill Fields burying-ground. The memorial at Dartmouth consists of two engraved brass tablets mounted on a large rough granite block. After the memorial had been unveiled by the Mayoress, Mrs. C. Peek, a wreath was placed upon it as a tribute from the Newcomen Society, which was formed last year to further the study of the history of engineering and technology.

Col. Howard Bury's latest dispatch from the Mount Everest expedition to the *Times* is dated from Tingri Dzong on June 26. It describes the fortunes of the expedition during the march from the Arun Valley up the valley of the Bhong. On the way a visit was paid to Shekai Dzong, an important administrative centre and the site of a large monastery. Major Morshead and his surveyors have already mapped some 25,000 square miles of new country along the route of the expedition. Rinderpest in the Bhong Valley necessitated the use of donkeys only for transport, but they proved quite satisfactory. Tingri Dzong, which is to be the main base of the expedition, is forty-four miles in a direct line from Mount Everest, which rises gradually from the plain of Tingri Maidan without any intervening ridges. Some six weeks will be spent at Tingri and its neighbourhood in reconnoitring the slopes, and the expedition will then move to Kharta to spend another six weeks examining the valleys on the east and north-east of Mount Everest. Mr. A. F. R. Wollaston has rejoined the expedition after accompanying Mr. Raeburn back to Sikkim, and later will visit the neighbourhood of Gosainthan for botanical researches. Col. Bury says that the western slopes of Mount Everest appear to be very much steeper than had been anticipated, but he believes that the east and north-east slopes present the fewest difficulties. The weather was cloudy, and the expedition was getting few distant views.

The first technical session of the International Commission on Illumination, the successor of the International Photometric Commission, was held in Paris on July 4–8. Those interested in illumination problems in Belgium, France, Great Britain, Italy, Spain, Switzerland, and the United States of America were represented at the session, which was opened by the Minister of Public Works, who welcomed the delegates in the name of the French Republic. The British delegates, nominated by the National Illumination Committee of Great Britain, were:—Major K. Edgcumbe (Institution of Electrical Engineers, chairman of the National Committee), Mr. C. C. Paterson

(hon. secretary and treasurer of the International Commission), Mr. A. P. Trotter (Illuminating Engineering Society), Dr. E. H. Rayner (National Physical Laboratory), Mr. L. Gaster (Illuminating Engineering Society), Mr. R. Watson (Institution of Gas Engineers), and Mr. J. W. T. Walsh (National Physical Laboratory, assistant secretary of the International Commission). The subjects dealt with by the Commission were as follows:—(1) The unit of candle-power at present in use in this country and in France and the United States was adopted for international purposes, and is to be known as the "international candle." It is maintained by means of electric incandescent lamps at the National Laboratories of the three countries named. (2) The definitions of the terms "luminous flux," "luminous intensity," and "illumination," and the units of these quantities, viz. the lumen, the candle, and the lux (metre-candle), were agreed upon. (3) The subjects of heterochromatic photometry (including physical photometry and the characteristics of the "normal eye"), factory lighting, and automobile head-lighting were also discussed at the meetings, and sub-committees were appointed to study the questions from the international point of view during the next three years. The new president of the Commission is Dr. E. P. Hyde, director of the Nela Research Laboratories of America, and Major Edgcumbe is one of the three vice-presidents. The next meeting of the Commission was provisionally arranged to be held in New York in 1924.

CORRESPONDENCE has recently appeared in the *Times* on the subject of State awards for medical discovery. Sir Ronald Ross urges (July 13) that a system of small pensions, somewhat on the lines of Civil List pensions, ought to be established in order to compensate medical men and others for work which has been of advantage to the public without being remunerative to themselves, the medical profession rightly objecting to medical discoveries or inventions being kept secret or monopolised by those who make them. Sir Ronald Ross mentions an example:—Dr. H. made during the war valuable additions to our methods of diagnosis by X-rays, particularly by the use of a cardboard scale. He appealed to the Royal Commission on Awards to Inventors, but was refused an award on the ground that the chairman had "such a high esteem of the noble ideals which the medical profession had adopted in forgoing personal advantage, giving their services free, and so on, that he was in favour of maintaining this spirit, and altogether against the idea that the Royal Commission could be persuaded to give an award to a member of the medical profession." This means, as Sir Ronald Ross pertinently remarks, that while the inventors of life-destroying devices may be rewarded by the State, those of life-saving devices are to be rigorously excluded! To this Mr. Tindal-Robertson, Secretary of the Royal Commission on Awards, replied (July 15), quoting the general practice of the Commission, and stating that in the particular case of Dr. H. the ordinary principle was held to apply, that the sale of any article, whether patented or copyrighted or not, necessarily includes the right to use the article. Sir Ronald Ross replied to this letter (July 28), admitting that the Royal Commission, on the grounds laid down, could not help, but urging that the powers of the Royal Commission should be enlarged so as to enable it to deal with the claims in question. He quoted the precedent of Edward Jenner, who received a grant of 30,000*l.* from the State. It is noteworthy that the British Science Guild and the British Medical Association last year advocated the payment of pensions on the lines suggested by Sir Ronald Ross, and that the latter body reaffirmed the principle at its annual meeting in July.

RECENT excavations at Pompeii, which have been in progress since 1911, have disclosed what may one day prove to be the most interesting part of the city, but the results are still jealously concealed from the visitor. A correspondent of the *Times* of July 26 is, however, in a position to supply some information regarding them. Passing through the well-known Strada dell' Abondanza, a compitum or crossing of two streets is reached, where there is a large sacred picture. Such places were held sacred, and were generally marked with sacred pictures and an altar, where propitiatory sacrifices were made to the Lares, who had houses and street-crossings under their special protection. The fresco now unearthed is divided into three sections, the first representing the twelve Penates or city guardians, beginning with Jupiter and Juno and ending with Diana. To the right of this painting, which is probably more interesting than any other found at Pompeii except that of the Villa Dionysius, is a sacrificial scene in which a large-winged demon serpent, the emblem of the Lares, is seen approaching the altar with two eggs and a pine cone as a bribe to it to avert the Evil Eye. Beneath is a real altar of masonry, on which are still preserved the ashes of the last sacrifice that was offered before the fatal August 24, A.D. 79. Archæologists will await with much interest the publication of these important discoveries.

IN a communication to the Ipswich and District Field Club Mr. Reid Moir describes the excavation of several barrows (sepulchral mounds) on Brightwell Heath, near Ipswich. Within a radius of 8 ft. in the middle of one, on the original ground-level, were found fragments of a pottery beaker dating from the early Bronze age and a number of flint scrapers and other implements, which the author claims to be able to distinguish from Stone-age specimens by an examination of their flaked areas. The study has hitherto been complicated by the habit of collecting *all* the worked flints from a barrow, whether belonging to a burial or scattered at random in the soil thrown up to form the mound, and possibly of much earlier date. Full-size drawings are given, with side-views and an analytical table of the 152 scrapers and 106 flakes found. Another barrow contained a burial of the earliest Anglian period, about A.D. 460, with a thin bronze bowl containing the cremated bones and originally covered with linen secured by a cord under the rim; also a bone comb and ornamented bone disc

closely resembling those found at Felixstowe, and now in the British Museum. The bronze bowl further contained part of an ivory armlet, two glass beads, and a clay draughtsman. Altogether an exceptional find that opens up a prospect of further successes on the Suffolk heaths.

Mr. E. E. Green contributes to the July issue of the *Entomologist's Monthly Magazine* part vi. of his "Observations on British Coccidæ." In the present article three species of Eriococcus are described as new to science. *E. glyceriae* is based upon specimens obtained from *Glyceria maritima* growing at Blakeney Point, Norfolk; *E. placidus* was obtained from a species of grass (? Festuca) at Thurnham, Kent; and the third new species, *E. pseudinsignis,* occurred on a similar food-plant in the same locality. Mr. Green has added much to our knowledge of British scale-insects during the past few years as the result of painstaking field observations. Although the family includes some of the most destructive of all insects, the British forms, excepting the common mussel scale and a few other kinds, are seldom observed unless by the trained specialist. In the same periodical Mr. J. E. Collin continues his descriptive keys of Anthomyid flies of the genus Limnophora, Desv., inhabiting our islands.

An interesting article on the biology and genetics of the very common ladybird beetle, *Adalia bipunctata*, is contributed by Mrs. O. A. M. Hawkes to the Proceedings of the Zoological Society for December, 1920. It is found that, although this beneficial insect will devour many species of aphids, it will not, for example, eat the common bean aphis except under stress of circumstances. Difficulties were experienced in the rearing of this and other species of ladybirds in captivity owing to their cannibalistic habit of devouring their eggs, larvæ, and pupæ. *A. bipunctata* has many colour forms, and these varieties offer suitable material for the study of inheritance of normally occurring variations. There is no evidence of dominance in crosses between its two chief forms, the red and the black, but matings of red with red produced only red with two exceptions. In matings of black with black both red and black forms resulted, but it was not possible to guarantee that the females had not had partners prior to the experimental tests.

Among the many activities of the late Mr. W. Denison Roebuck, of Leeds, none was pursued with greater determination than the collection of records of the distribution of land and fresh-water mollusca in the British Isles. Beginning in 1877, he was still adding fresh data up to his death in 1919, and the summary results of the 59,000 entries in his books are published in the last issue of the *Journal of Conchology* (vol. xvi., No. 6). No record was admitted to his "census" unless specimens had been seen and verified by referees appointed by the Conchological Society. The distributions ascertained by this accurate and painstaking work are set out in tables under 153 topographical divisions based on those devised by H. C. Watson, and are also shown for more than 150 species in five plates of small, but clear, maps. The whole forms an account which should be of substantial value not only to conchologists, but also to students of geographical distribution. It is to be hoped that its publication will stimulate naturalists to deal with other groups in the same way, and by collaboration render the enormous mass of data which must exist in individual collections of more general service. British entomology suggests itself particularly as a field in which important results might readily be obtained by systematised effort. Copies of Mr. Roebuck's work may be had from Mr. J. W. Jackson, University Museum, Manchester, at 5*s*. each.

A memorandum to the Government of India regarding the probable amount of monsoon rainfall in 1921 was issued by Dr. Gilbert T. Walker, Director-General of Observatories in India, dated June 7, 1921. The monsoon rainfall is affected by previous conditions over different parts of the earth, and these conditions have been on the present occasion unusually divergent. In India the development of the monsoon on the western side of the Peninsula had up to date been less vigorous than usual. Examining one of the features of interest, it is shown that scarcely any snow fell during the preceding winter in Baluchistan and very little on most of the hills of the North-West Frontier Province. The total winter precipitation over these areas is said to be the lowest for at least twenty years. Dr. Walker summarises the conclusions to be drawn from the controlling features with a statement that it would be unjustifiable to attach any importance to indications so feebly marked as those of the present year, and he adds that when their resultant effect is so trifling nothing is gained by attempting to reach a conclusion, and he does not consider the controlling factors decided enough to enable a trustworthy forecast to be prepared.

So far as efficiency and durability are concerned, there does not seem much to choose between the electrical and the mechanical methods of connecting the propellers of a ship with the steam turbines. Excellent results have been obtained by both methods. The electrical method, however, has much greater flexibility. There is no necessity to have the turbines near the shaft, and its direction of rotation can be reversed with the greatest ease. In *La Nature* for July 16 L. Jauch, the chief mechanician of the French Navy, compares the two methods, and concludes that the electrical drive will be much the more popular in the future. He points out that five battle-cruisers each requiring 180,000 h.p. and using electrical methods of driving the propeller are being built in America. The author calculates that at maximum power the efficiency of the mechanical type of gearing would be 2 per cent. higher. But this is offset by a 2 per cent. gain in favour of the electric drive at mean speeds and a 20 per cent. gain at low speeds. He points out that with the electric drive there is no fixed relation between the speed of the propeller and the speed of the steam turbine. Hence the latter can always be run near the speed at which its efficiency is a maximum.

The Department of Commerce, Bureau of Standards, Washington, has just issued Circular Paper No. 100 on "Nickel" (20 cents). This is one of a

series describing the physical properties of metals, together with a discussion of the relation of these properties to the composition and treatment of the materials. In it are described the properties of nickel and of its commercially important alloys: nickel-steel, ferro-nickel, copper-nickel, and nickel-chromium alloys. The pamphlet is illustrated by numerous photomicrographs and curves, and provided with a very complete bibliography. The collection of data will be valuable to metallurgists.

THE Wireless Press, Ltd., announces for early publication a volume by Prof. J. A. Fleming, who was recently awarded the Albert medal of the Royal Society of Arts in recognition of his many valuable contributions to electrical science. Under the title "Fifty Years of Electricity: The Memories of an Electrical Engineer," the work will record the progress of electrical engineering since 1870, the year in which Prof. Fleming attained his majority.

THE catalogue of optical instruments recently issued by Messrs. Adam Hilger, Ltd., 75A Camden Road, London, N.W.1, contains details of a number of instruments not previously obtainable in this country. Amongst them may be noted a monochromatic illuminator, an infra-red spectrometer, a vacuum spectrograph, a linear thermopile, a spectrophotometer, and several refractometers. Messrs. Hilger are offering a limited number of their instruments at a special reduction of 20 per cent. off their current prices.

ERRATUM.—We regret that the price of the fifth edition of Sir J. J. Thomson's "Elements of the Mathematical Theory of Electricity and Magnetism" was incorrectly given in NATURE of July 21, p. 647, as 30*s.* net instead of 25*s.* net.

Our Astronomical Column.

DISPLACEMENT OF LINES IN THE SPECTRUM OF VENUS.—The *Astrophys. Journ.* for June contains a paper by Dr. Chas. E. St. John and Mr. Seth B. Nicholson, in which they test the result announced by Mr. Evershed that his Venus spectrograms supported the view that the earth exerts a repulsive effect on the solar gases, analogous to that which the sun appears to exert on comets' tails. The authors took two series of Venus spectrograms: in 1919 with Venus east of the sun, and in 1919–20 with Venus west of the sun. Their analysis of the results leads them to conclude that the effect can be correlated with the altitude and the angular diameter of Venus; hence they conjecture that it is due to atmospheric dispersion, the centre of the visual image which was adjusted on the slit differing from the centre of the photographic image. They propose in future to take some further plates viewing the image through a blue screen, which should eliminate the above source of error. They have incidentally examined the measures to see if they afford any evidence of a rapid rotation of the planet, but conclude that "the difference between the morning and evening series . . . is not of an order that would indicate . . . a rate of rotation higher than that found by Slipher." In all the plates of the series, whether on Venus, the sky, or the sun, an iron-arc spectrum was photographed simultaneously.

PLANETARY PHOTOGRAPHY.—Pubns. Ast. Soc. Pacific, June, 1921, contains a lecture by Mr. E. C. Slipher on this subject, illustrated by numerous reproductions of photographs of Venus, Mars, Jupiter, and Saturn. Those of Venus failed to record any surface markings, but illustrate the changes of diameter and phase that occur in the synodic period. The photographs of Mars taken at Flagstaff are stated to number 100,000. Numerous exposures are made on each plate, in the hope that some will catch the moments of best definition. Mr. Slipher gives a long list of features that he claims can be verified from the plates. It must, however, be admitted that not all of these can be seen on the reproductions, though they may be visible on the original negatives. The polar cap is shown with great clearness, and it would seem to be worth while to make measures of its position angle in order to obtain an independent determination of the position of the axis.

The photographs of Saturn yield much interesting information. The great excess of luminosity of ring B over ring A, and the semi-transparency of the latter, permitting the outline of the ball to be seen through it, are well brought out; also the faintness of the ring when the sun is near its plane. There are reproductions of two exposures on April 28 last, when the earth and sun were on opposite sides of the ring-plane. There is a dark stripe across the centre of the disc, formed by the dark side of the ring and its shadow; it is narrowest in the middle, the two edges being curved in opposite directions. One feature shown in all the photographs is the extreme regularity of the fivefold belt in Saturn's southern hemisphere. The edges appear to be exactly parallel to the equator. One is inclined to mistrust this regularity on drawings, but the photographs are free from bias.

MEASUREMENT OF THE DIAMETER OF ARCTURUS.—Mr. F. G. Pease (Pubns. Ast. Soc. Pacific, June, 1921) gives an account of the work with the interferometer on the 100-in. Hooker telescope at Mount Wilson since the successful measurement of the diameter of Betelgeuse. Observations on Arcturus in February and March, with poor seeing, showed some diminution of the visibility of the fringes with increasing distance between mirrors. At length on April 15 the seeing was perfect, and the fringes were found to disappear when the mirrors were separated by 19·5 ft. As the maximum separation at present is 20 ft., it was not possible to proceed to the next point of greatest visibility of fringes; but the value 19·5 is considered to be correct within 0·5. Assuming an effective wave-length for type K0 as 5600, the angular diameter of Arcturus is 0·0237″, very near the mean of the values estimated by Eddington, Russell, and Hertzsprung. The parallax is taken as 0·116″ from the mean of the best recent measures, giving a linear diameter of 19,000,000 miles, or twenty-two times that of the sun.

Observations of Aldebaran on nights of poor definition give grounds for thinking that its angular diameter is somewhat greater than that of Arcturus; Pollux and α Ceti give indications of weakened fringes, but probably a longer beam than 20 ft. would be needed to make them disappear. The mirrors have hitherto been moved by hand, which has taken much time. Two screws driven by a single motor are now being mounted, which should greatly facilitate the measures.

The Universities and Technological Education.[1]

By PROF. W. W. WATTS, F.R.S.

TECHNOLOGICAL education may be defined as the development of those sides of learning which will enable us to extract the highest possible good from the resources of the world, and in the process to make life at least endurable and, if possible, pleasant to the maximum number of people; to avoid waste and extravagance in both production and use; to keep and leave the world beautiful and peaceful; and to do all this with such a margin of economy as to deplete as little as possible our children's heritage in the earth of which we are but tenants for life.

In the use of every kind of resource, animal, vegetable, or mineral, man has been woefully extravagant, partly through thoughtlessness, but mainly through ignorance. To take their share in improving this state of things is a task not unworthy of the greatest and most ancient universities, as well as of those of newer growth, and of those other institutions which, because of their heart-whole and deliberate devotion to this end, are not yet deemed worthy to be reckoned as universities.

Among the functions of these universities and institutions should be the training of men who are to lead the industries forward in the direction of higher efficiency, smoother and more salutary working, and increased production; men who shall know sufficient of the laws of Nature to extract through their operation all the energy and material to which we are entitled, and who never forget that Time the Avenger, tardy but sure, will exact from them the penalty for any thoughtlessness or neglect.

The Student.

It is fair to demand that the technological student should come from school with a really good general education and the culture which such an education should give. He should have such a knowledge of languages that he can not only use those he knows, but will also be able without great difficulty to acquire any other which may prove essential to him; such an acquaintance with literature that he really understands how to read and extract from the printed word what it is able to give him; facility in writing clearly and intelligently; so much knowledge of geography and history as will enable him to get hold of any information he may require; and a thorough grounding in mathematics and elementary science.

In the study of the group of sciences and arts germane to the professional training, the best that can be done is to pick out in each subject those matters which are common to a number of technological subjects, to teach them to mixed classes of convenient size, and to supplement them where necessary by special additional instruction or direction. The amount of common matter is much greater than is generally supposed, and such courses, if thoughtfully designed, will go a great part of the way. Here the strength of broad-based institutions is manifest, for in them it is possible, without undue expense, to make use of all existing departments. There must necessarily be either incompleteness or waste of effort and overlapping in the case of institutions devoted to a single branch of technology; and such institutions should never be founded unless it has been proved impossible for bodies of university rank to undertake the work.

[1] From a paper read before the Congress of the Universities of the Empire at Oxford on July 6.

Curricula.

It is as well to insist that technology must be based on a thorough knowledge, practical and theoretical, of the relevant sciences treated as pure sciences. In the past most industries have advanced by means of a cumbrous and exclusive course of trial and error. It is only in the more recent developments that advantage has been taken of the principles and general laws worked out by the scientific man in his laboratory, the royal roads in both the pursuit and the applications of science. In future the technologist must be a scientific man, not only in his knowledge, but also in his attitude and outlook. In his life-work he will not be really successful if he is satisfied with things that are. He is to be the introducer of new things in a *régime* which may fallaciously appear to have reached finality. This he can be only if his knowledge is wide and so ingrained in him that he can make full and practical use of it.

In every science the great aim should be to bring out the principles and the general laws which have been established, the lines of thought and experiment on which they rest, the means by which they can be and have been tested, and the consequences which flow from them. The teaching scheme is thus made easier as well as more efficient, for such principles are common ground, equally necessary to each branch of technological instruction. It is in the illustration of them that the teacher must bring out their contact with the technical practice of industry.

While holding fast to the principles of science, it is essential that the scheme at this stage should be exceedingly elastic and capable of rapid variation to meet the advance of industrial applications. What is at once the hardest task and the severest test of the successful teacher is not how much he can teach, but how much he dare leave out. In any case, he must be firm in meeting the question which few of us escape: "What use is this to me?" He can see farther than his students, farther even, perhaps, than his technical advisers, and he should be able to show that such apparent superfluities are like the hidden strands in concrete, without which the material would fail under some of the stresses it is designed to meet. It is his duty to remember that, whatever may be a student's intentions as to his future, he cannot be sure of controlling that future.

The guidance of technical advisory committees is of inestimable advantage, not only in the later year or years when purely scientific work is merging into the technical applications of it, but also to some extent while pure science is being studied. In both cases, however, their function should remain advisory and never become mandatory. The last word must rest either with the director or principal teacher, or with the faculty of which he is a member.

In the later year or years of the course the instruction will naturally become more highly specialised, and if the previous scientific training has been thorough and sound and the student has learnt how to make practical use of his knowledge, progress will usually be rapid.

It is essential, too, that at this stage, but preferably earlier as well, the student should be trained in writing of what he has learnt, or in summarising the results obtained by his own practical work, in clear and concise and, if possible, non-technical language which can be easily understood by the type of man under

whom his professional work will be carried on. By this he will be able to display most clearly how much of his work he has really grasped and how far he sees into its consequences, while he will, at the same time, be acquiring a gift of great service to him in his career.

Touch with Industry.

It is a vital question at what stage contact with industry should be initiated. Until a student knows some of the features of the industry in which he will be engaged, he finds it difficult to realise the significance of many parts of his training. On the other hand, if he goes into the shops, the works, or the mine too soon, he is not possessed of enough knowledge to profit fully by his experience. The advantage of early touch outweighs its disadvantages, and contact should begin early, and be renewed at several stages of the course. The student may at first gain little actual knowledge in the mine or workshop, but in working there for a period by the side of the men whom he will afterwards direct he will gain a most valuable knowledge of their customs and limitations, their predilections and weaknesses; and he will be laying down a foundation of experience which will usefully guide him when he comes to the difficult task of handling men himself. At the same time, while watching the technical skill of the expert workman, he will acquire respect for accuracy and delicacy of workmanship and for that astonishing proficiency which prolonged practice alone can give. What is of scarcely less importance is that at this stage he will hear a whole gamut of technical nomenclature which has before been mere jargon to him, if he has met with it at all. No one is more intolerant of the phraseology of the expert than the "practical man," but no one is more tenacious of his own terminology. It is well that the student should learn the latter while he is still in the position of the under-dog, so that it may not trip him up later. As his course proceeds it is natural that workshop and field experience will become of greater educative value. He will be entrusted with higher work and so gain new experience.

Directors and Teachers.

One of the greatest difficulties in the future, as it has been in the past, will be the staffing of technological departments. Such departments must be directed by the right kind of men—men not only of good intention, but also of wide industrial knowledge, capable of dealing with students and of organising their staffs; men of ideas and energy, devoted to their own research and that of others; and, above all, men of achieved success. There seem to be but three ways of securing such men: (1) To pick the right man whenever and wherever found, pay him his price, and leave him to teach as and what he thinks best and to select his *personnel* and material, as well as his methods and lines of research; (2) to take from the industrial side men who have made their mark and a competence, but, from interest in their subject and love of the work, are willing to continue in harness in what is one of the pleasantest, if not the least exacting, of professions; or (3) to select competent and trustworthy men who have found touch with industry from the academic side, and to allow them to supplement their pay by private professional work conducted under proper restrictions. Under present conditions the universities will have to fill their posts from the last two classes.

Subordinate staffs have also to be considered. Here again the pay is generally inadequate to secure the services for long periods of the most desirable men, and it is arguable that it is well this should be so. There are many inducements to attract men to the staffs of applied science departments: the continuation of their technological education and the possibility of obtaining higher degrees, the developing of their teaching ability, the opportunity of increasing their proficiency in research and improving their status and reputation thereby, the earning of additional pay by carrying out industrial work of research character or otherwise, and the introduction to, and contact with, industrial men who will eventually have research work to dispose of or employment to offer. It is essential, however, that means should be provided to retain some, and those not the least promising, for longer periods in order to give stability to the department and to the head of it the responsible support which he is entitled to look for.

It will also be to the advantage of every department that it should be sufficiently strong to allow one or other of its members to take an occasional period of time for the purpose of study, research, or even business work. This would react not only on the value of the teaching, but also in spreading the reputation and increasing the efficiency of the department by maintaining closer touch between it and the business world. If well managed, it need not involve heavy additional cost. It is chiefly a question of organisation and of a liberal outlook.

Research.

It is essential that research should form part of the curriculum of every technological student. Whatever his future career, in addition to routine work, it is certain that he will come across new conditions and new difficulties, something for which he may have met no precedent—problems, in other words, which need to be investigated on scientific lines before they can be solved. It is not essential that the research should be other than of a purely scientific nature. What is essential is that he should get to realise that the easiest and quickest way may often be to obtain facts and inferences at first hand, that he should learn how to question Nature, and acquire confidence that, if he can put his questions skilfully, he will usually obtain, after Nature's way, an answer which will contain, though it may conceal, the solution to his problem.

It is still more necessary that the teachers should engage in research, and naturally this in most cases would have some more or less direct bearing on industrial problems. Apart from the fact that only a man engaged in the production of new knowledge can be a really first-class teacher, in no other way can he establish contact with the highest development of the industry in which he is interested and thus secure the confidence and respect of those engaged in it. An active research school is the best symptom of a live and active technological, as it is of a scientific, department; it tends to attract the right kind of student, trains the best kind of staff, and is a legitimate way of keeping the department before the eyes of business men.

If it is possible to pass the best students on to the staff for a short period before they take up outside appointments, and to afford them reasonable leisure to embark upon research, the school will be much strengthened and the worth of the students considerably enhanced. A certain amount of teaching work is by no means a drawback, for it will enable them to consolidate their knowledge and render it more accessible when wanted. A larger staff than otherwise may be thus maintained, and the department will be more stabilised in the event of having to face the possible loss of one or more of its senior members.

Another consequence of a strong research school will be to attract from outside those engaged in industry who have special problems of their own to solve which cannot be so well dealt with in the laboratories to which they have access in works or elsewhere. This should, of course, receive encouragement. The introduction of outsiders of the right kind to the laboratories is of service in several ways. It "spreads the light" by keeping industrials informed as to the progress of science and the improvements of methods of investigation, and as to the precise nature, cost, and limitations of scientific inquiry. It impresses upon them the necessity for experimental accuracy, and shows how closely the sciences are now interwoven, and how results obtained in one science or branch may be imported to assist progress in another. Better relations are established between the institution and the industries surrounding it, mutual confidence is engendered, and personal acquaintance is encouraged to the advantage, on one hand, of the industries, and, on the other, of the students who may find eventual employment therein.

A corollary is that in certain cases research by staff or students may be in part carried on in works laboratories outside the university, and the considerations just set out apply as well to this case. Care is requisite that industrial research should not degenerate into anything of the nature of routine or testing work. This should be excluded, and the universities should not in any way compete with firms which specialise in this direction. Only where this class of work involves problems which are new or exceptionally difficult, or need the employment, or even formulation, of new principles, should it be undertaken by university departments.

The Product.

The type of man which it should be the aim of the universities to turn out should possess those qualities which distinguish the best type of scientific man—not merely knowledge of his subject and technical ability to use that knowledge, but capability to introduce the scientific method into his conduct of everyday life and into his dealings with his colleagues and subordinates. He must be willing to study *all* the conditions of his problems before he is sufficiently satisfied with their solution to carry them into effect. These conditions require, not *a* solution, but *the* solution which can be brought into operation with the least possible disturbance of the things that are, without needless change of raw material, machinery, or *personnel*, but with the advantage of diminished cost, enlarged production, and increased value or efficiency.

If this is the aim, the product will be the best type of technologist. He will not necessarily be the type of man suited to occupy immediately the highest position in his business. But the work given him to perform will be so well done that it will be impossible for his character, competence, and ability long to escape the watchful attention of his chiefs. It will not be long before he is chosen for more and more responsible work until he attains high rank in his profession. I do not believe it is possible that men of managerial type, captains of industry, will ever be technically trained as such. The universities should endeavour to produce such a type of man that his superiors will take him by force, and almost against his will, from his technological work to direct the bigger issues.

Conclusions.

(1) As much as in any other walk of life, the education of the business man must be a liberal one. His mind must be as agile, and he must be as well provided with intellectual weapons, as any other well-educated man.

(2) A course of technological education thoughtfully laid out is, as an instrument for mind-training and in the nature of the product turned out, in no way inferior to the higher branches of language, literature, history, or philosophy. The work is as hard, the problems to be solved as difficult, the reasoning as acute, the intellectual joy in success as great; while its urgency to the nation and to mankind is one of the most pressing matters that educationists have to face.

(3) In the multiplicity and complexity of subjects there is no longer time for the most liberal of educations to be as broad as heretofore. Some universities are even specialising in a single dead language as an honours subject, holding, perhaps rightly, that a thorough knowledge of one is better than what can be attained, in the time available, of two. Technological education has anticipated this specialisation only by a few years.

(4) There is no less worthiness and dignity in the newer education than in the old. All higher education is, and always has been, technological. The learning of the older universities has been used, and has even been moulded for the purpose, to equip the parson, the poet, and the politician; and both the peer and the proletarian can gain from the study of classical literature some facts or theories to guide them in their respective vocations.

(5) The business man has good right to demand that institutions of university rank shall supply his demands as well as they have dealt with education for the professions. The polytechnic system has not had the success that was expected in educating his foremen and workmen. He must not be again disappointed when he seeks higher education for himself. He expects, and has a right to expect, that the type of education he needs shall be, not a by-play or a by-product, but a worthy aim in itself; and if the universities will not give it to him, he will take his own steps in the matter.

The Exploitation of Irish Peat.[1]

By PROF. HUGH RYAN.

THERE are about 6,000,000 tons of turf used every year in Ireland, but this quantity is almost insignificant in comparison with the total amount, about 4,000,000,000 tons, which can be won from the bogs of the country. The Irish Peat Inquiry Committee, of which the present writer was a member, was appointed to suggest what means should be taken to ascertain the conditions under which the peat could be profitably won, prepared, and used in the most favourably situated localities. The main report of the Committee, which is contained in the publications under notice, recommended the purchase by the State of a large bog in which hand and mechanical methods of winning peat could be tried side by side. These tests would require to be continued over a long period if

[1] "The Winning, Preparation, and Use of Peat in Ireland." Reports and other Documents. (Fuel Research Board. Department of Scientific and Industrial Research, 1921.) 3s.

they were to give trustworthy data, and they would have resulted in the winning of large amounts of peat, for which there would be little prospective market. With the view of decreasing the net expense of the experiments and at the same time of testing, on an adequately large scale, the commercial possibility of utilising peat for the generation of electric power, the Committee suggested the installation of an electric power station on a suitable area of the Bog of Allen, within 25 to 40 miles from Dublin. A portion of this power could be used locally to drive the peat-winning machines or agricultural machinery, in chemical industries, such as the manufacture of calcium cyanamide, and for lighting and power purposes in the neighbouring towns. The excess of electric power could be transmitted in bulk to the power station at Dublin.

As a result of a conference with the Fuel Research Board the Irish Committee submitted a much less ambitious, if less satisfactory, scheme, which consisted briefly of the purchase of a bog of about 10,000 acres at a price of about 2*l*. an acre, and the establishment in it of an experimental station to test the various methods proposed for winning peat. Even on this scale a considerable number of labourers would be required, and in order to encourage these to settle in the district the Committee proposed to have experiments conducted by the Department of Agriculture for Ireland on the reclamation of cutaway and virgin bog. The Fuel Research Board approved in general of this scheme in 1918, but the agricultural portion of the scheme was referred to the Irish Department of Agriculture about two years after the Peat Committee had submitted its report. The present publications contain also the report of the Sub-Committee on agricultural matters appointed by the Department of Agriculture. Owing to this unfavourable, and to a large extent unjustifiable, report of the Sub-Committee, it is not proposed to carry into effect the recommendations of the Irish Peat Inquiry Committee with regard to the winning of peat.

A serious obstacle which confronts everyone who attempts to devise a scheme for winning peat on a large scale is the labour difficulty. The peat-fuel season, depending on air-drying as it must do for commercial reasons, lasts only about four to six months of an average year. It is not easy, therefore, for the peat industry to attract the labourers required by it from other industries which offer them constant employment throughout the year. This applies especially to the men required for cutting and spreading the peat. Much of the work of the drying operations can be done by women and boys, who are in general available during the late summer months in any more or less thickly populated district. One of the chief problems which the Peat Committee had to consider was, therefore, how to limit so far as possible the number of men necessary for the winning of a definite quantity, say 250 tons, of turf each day of the cutting season (120 days). The same difficulty was experienced abroad, and was, to some extent, met there by the introduction of labour-saving devices such as the automatic machines of the Baumann and Wielandt types.

FIG. 1.—Baumann's automatic peat machine.

The Baumann machine consists of a ladder dredger which scrapes the peat off the inclined face of the bank and conveys it to the hopper of the cylindrical mixer and macerator, shown on the right-hand side of Fig. 1. The peat is pressed through the mouthpiece of the macerator as a rectangular band which is automatically cut into sods. The latter are caught on plates moving in a lattice girder, extending about 120 metres over the adjacent drying ground. When the lower half of the continuous chain of plates is completely filled with sods, these are tipped on the drying ground and the emptied plates return to the macerator over the upper portion of the latticed girder. One of these machines in Raubling Bog, Bavaria, attended by a gang of five men, had a daily output of spread sods corresponding to 55 tons of air-dry turf. Its dredger was driven by a 20-h.p. electromotor, its macerator by a similar motor of 40 h.p., and the cost of the complete machine was 1500*l*.

The Wielandt machine is similar in principle to the Baumann, but lighter in construction, largely owing to the adoption in it of a different spreading mechanism. The machine can be driven by a 25-h.p. electromotor, and its total cost, including motor and cables, was 1000*l.* four or five years ago, but is now much higher. During the war it was found at Elisabethfehn, in Oldenburg, that one of these machines, attended by one man and three or four youths, had an output in the season of 7000 tons of air-dry turf.

If the statements made abroad with regard to the efficiency of automatic machines are correct, four of these machines, attended by sixteen men in all, can dredge, form into sods, and spread in a day enough peat to yield, when air-dry, about 250 tons of turf. The same output of peat, cut and spread, by the method ordinarily practised in Ireland requires about 160 men. It is therefore a matter of great importance for the winning of peat on a large scale in Ireland that these claims should be subjected to a prolonged test under the conditions obtaining here. In conclusion the writer must again express his regret that the recommendations of the Peat Inquiry Committee were ultimately set aside for reasons which are in part due to misinterpretation of the Peat Committee's report, and in part to statements which were made by the Agricultural Sub-Committee, and are in sharp disagreement with the actual facts, in regard to the extent and the purchase price of Irish bogs.

Geophysical Problems.

A SURVEY of research problems in geophysics has recently been published by the American Geophysical Union, a body which acts as the Committee on Geophysics of the National Research Council, and as the United States National Committee of the International Geodetic and Geophysical Union. The survey consists of a series of seven essays by the chairmen of the several sections of the union, dealing respectively with geodesy, seismology, meteorology, terrestrial magnetism and electricity, physical oceanography, volcanology, and geological physics and chemistry. It is interesting to observe that the two latter subjects, so little studied in this country, are in America found sufficiently important to occupy separate sections of the union.

Advance in nearly all these branches of geophysics seems to depend on much the same method of attack, involving on the one hand an enormous amount of organised, co-ordinated labour of observation and measurement, and on the other individual theoretical study, necessarily of a freelance character, by a comparatively few people with scientific training, insight, and wide knowledge, at research institutes or universities. The first half of the task is being executed with increasing skill and success by the national scientific organisations of the leading countries, but the complementary half lags behind. Dr. C. F. Marvin, for instance, after describing the present achievements and future tasks of meteorological organisations, concludes that "seemingly the greatest need in meteorology is that of a master mind to direct itself comprehendingly and intensively to the great problems which the science still presents." The recency of the beginning made by meteorologists in the study of the upper air, now recognised to be fundamental for the upbuilding of a dynamical science of meteorology, suggests that perhaps also in other geophysical sciences progress may be obstructed by failure to perceive vitally important directions which observation and research must take.

The outstanding task of geodesy at the present time is described by Prof. Bowie as being that of co-ordinating the geodetic triangulations of the various countries by reducing them to a single datum, defined as the adopted latitude and longitude of some one station, the azimuth of a line radiating from that station, and the dimensions of the reference spheroid on which the triangulation is computed. This involves a herculean work of re-computation and re-adjustment of the triangulation networks, especially in Europe; in America much progress in this direction has already been made. Gravity surveys must be extended over the land surfaces, and a satisfactory method of observation evolved for the ocean areas of the globe; this will afford information as to the variations of density in the earth's crust, enable the theory of isostasy to be further developed, and thereby lead to ever closer approximations to the figure of the earth.

In seismology the most important world-wide problem is the accurate determination of the time taken by earthquake waves to travel from their origin to other points on the earth's surface; this information is necessary in order that the origin of earthquakes arising in inaccessible (land or oceanic) regions may be determined, and that the velocity and path of the waves within the earth may be deduced, thus throwing light on the earth's internal constitution. Prof. Reid expresses the opinion that the most useful means to this end lies in the improvement of the equipment of existing seismological observatories rather than in multiplication of the present number. The desirability also of methodical studies of limited areas where small shocks are frequent and strong ones occasional is also mentioned, with the view of determining the sequence of events leading up to the rupture producing a strong shock, and possibly of forecasting the region and time of such occurrences.

Dr. Bauer's article on terrestrial magnetism contains some interesting remarks on the progress of the analysis of the earth's magnetic field which is now being made in the department of the Carnegie Institution which he controls. It has been concluded that for many purposes the theoretical formula proceeding in series of spherical harmonics may be restricted to the few most important terms, leaving the residual field, representing continental and more local irregularities, for special study and treatment in accordance with their extent and character. Reference is also made to the important problems afforded by the magnetic variations, both those connected with auroræ and earth-currents, and the rarer ones occurring at times of solar eclipse. The baffling fundamental problems of the origin of the earth's main magnetic field and the cause of its secular variation are also touched upon.

Prof. Littlehales points out the influence which the ocean, being so large an expanse of the substance having the highest known capacity for heat, must exercise as a factor governing the distribution of terrestrial temperature, and the consequent importance of oceanography to geophysics in general. A *résumé* is given of the efforts so far made, by voyages of exploration and by investigations in marine laboratories, towards the study of the oceans in their many aspects; the system according to which progress is now being sought is the study, in detail, of definite oceanic stations periodically revisited every three

months, for the purpose of making synoptic charts of temperature, salinity, gas content, currents, and so on, which it is hoped will prove amenable as material for mathematical investigation of the related phenomena.

In his essay on volcanology Dr. H. S. Washington describes the information which requires to be collected for the systematic study of the subject, and the programme of a volcanic observing station, such as those which have been established for some years at Vesuvius and Kilauea. The article on geophysico-chemical problems, by Dr. R. B. Sosman, of the Carnegie Institution Geophysical Laboratory, concludes the report, and deals with the investigation of the physical properties and chemical reactions of the substances and aggregates which make up the earth.

Agricultural Research.

"THE Present Position of Research in Agriculture" formed the subject of a lecture delivered by Sir Daniel Hall at the Royal Society of Arts, and reported in the society's Journal for April 1 (No. 3567, vol. lxix.). Up to the time of the formation of the Development Commission in 1909, agricultural research was entirely unrecognised by the State. A considerable amount of information had been gained from the researches at the Rothamsted Experimental Station, which was started in 1843, and was entirely dependent on the endowment provided by its originator, Sir John Lawes; valuable researches were also being carried on at the Woburn Station of the Royal Agricultural Society, while from 1890 onwards the various agricultural colleges were commencing investigations along many different lines. To work of this kind the State granted not more than a few hundred pounds a year, and the Development Commission was expressly charged with the object of formulating some scheme for the promotion of research. The scheme adopted is now in working order, and by it the field is divided up into a number of subjects, one of which is allocated to each university or institute. By this means research is removed from immediate State control, concentration of effort ensured, and overlapping avoided, and each institute is able to carry out a continuous scheme of work. The question of the State control of research is one which is hotly debated. On one hand it is argued that the State pays, and therefore should control the expenditure; on the other, when the nature of research work is considered, it is obvious that the looser system of control prevailing in a university is much more productive of good work than the rigid methods of a Government department, while the type of man wanted for research is much more attracted to the former than to the latter. Moreover, if research came directly under Government control, then the programme of work would have to be submitted annually to the judgment and criticism of administrative bodies possessing no expert knowledge. That such a procedure is disastrous has been proved many times in other countries.

Another advantage arising out of the association of the research institutes with the universities lies in the co-operation thereby ensured with other workers in all fields of science, so that no matter in what direction the particular research may extend, the advice of men with expert knowledge is always available. It is also of the utmost importance to keep agricultural research in contact with the business of farming, and this is attained most easily through association with a university which teaches agriculture and is in touch with the surrounding farmers.

At present there are under the scheme eight institutes, each dealing with some particular branch of agricultural research, such as plant pathology, fruit-growing, dairying, etc. A research council, consisting of the directors of the various institutes, together with a few independent scientific men and the officials of the Government departments concerned, has been set up to ensure the co-ordination necessary between the different research centres. To this body also the Ministry is able to submit plans for any large-scale investigations requiring the co-operation of a number of the institutes. An important feature of the scheme has been the provision of a number of advisory officers who are attached to the various agricultural colleges. These men are free from most teaching duties, and are able to give advice and help to the farmers and horticulturists in their area while keeping in close touch with the directors of the related institutes and the officers of the Ministry's staff. In this way a systematic service is secured capable of dealing with plant pathology, etc., all over the country.

The total funds set aside in the current Estimates for this research scheme amount to 105,000*l.*, against 38,250*l.* for the year 1913–14. This ensures for each institute a definite number of salaried posts with reasonable prospects of promotion, so that agricultural research is no longer an absolute blind-alley employment.

The immensely important subject of animal disease has been very inadequately dealt with, but the many difficult questions involved are being investigated. The Ministry is now supporting a research laboratory at Addlestone, and grants are made to the Royal Veterinary College and the London School of Tropical Medicine for the pursuance of researches in animal diseases.

Having dealt with the organisation of research, the lecturer gave a short account of some of the most important practical results obtained recently from the various institutes. At Rothamsted a valuable investigation has been carried out on the method of the decomposition of farmyard manure. A cellulose fermenting organism was discovered which attacks straw in the presence of active nitrogen. At the same time there is considerable loss of nitrogen, so that it is most essential to protect the ordinary dung-heap from washing by rain, and also, in the case of rich cake-fed dung, it must be got on to the land early if heavy losses of nitrogen are to be avoided. Some of the principles emerging from this work have been very successfully applied to the treatment of sewage. At present the valuable nitrogenous compounds in sewage are mostly wasted, but by passing it through a straw filter bed under certain conditions some 60 per cent. of the nitrogen is removed by the organisms decomposing the straw, which thereby becomes a good manure, and, moreover, the effluent is harmless. Further trials are in progress with the object of making farmyard manure on a large scale without animals.

At Aberystwyth plant-breeding methods are being applied to grasses and clovers, while at Cambridge the scientific breeding of farm crops has given most valuable results; wheats have been produced which add 10 per cent. to the yield of the farm, while some of them combine the strength of the Canadian with the cropping power of the English varieties.

In connection with animal nutrition the Cambridge station is trying to obtain growth-curves showing the relation between the food consumed, the live and dead weight, and the useful meat, fat, and offal for each stage of the animal's development, while the station at Aberdeen is paying particular attention to the importance of vitamins in the nutrition of farm animals.

At Long Ashton and East Malling researches are being made in fruit growing and preserving, so that some quick method of storing fruit for future use may be available whenever a glut occurs in the market. Research on plant disease is being conducted more with the object of producing immune varieties than of finding curative methods. That this is the right line to take is shown by the fact that whereas all attempts to free a soil from wart-disease infection have been unsuccessful, there are certain immune potatoes which will grow without blemish in the most heavily infected soils.

The lecturer remarked that although our organisation for agricultural research is young, and we cannot compare with America or with Germany before the war, either in the number of workers engaged or in expenditure, yet "it is not too much to claim that the majority of really fruitful ideas and conceptions that have recently been current in agricultural science have sprung from English laboratories."

Meteorology of the Philippines.[1]

THIS work is rightly claimed in the preface by the director of the Philippine census to be of "great practical value." Observations from sixty official stations and fifty-three voluntary stations have been dealt with, and the maps and plates aid much in the simplification of the large amount of data contributed to the world's meteorology. The elements dealt with are temperatures, rainfall, humidity, cloudiness, wind direction and force, and typhoons.

Temperature is treated, as to both exposure and method of obtaining averages, in a manner quite comparable with the most approved European system. The mean annual temperature for the whole archipelago obtained from stations near the sea level is 26·9° C. (80·4° F.). The seven warmest months are April to October, and the five coldest November to March. May is the warmest, and January the coldest. Tables are given showing in great detail the mean, extreme, and range of temperature at all stations.

Rainfall distribution throughout the year forms the most interesting feature of the weather of the Philippines. The exposure to the prevailing winds occasions great differences in the amount of rain, in spite of the relatively small extent of the archipelago. The winter rains come direct from the Pacific and cause large falls over the eastern part of the archipelago; these are called the north-east monsoon rains. The summer and autumn rains are due chiefly to the influence of typhoons; these rains are most abundant in Luzon and the Visayas. The thunderstorm rains which occur in spring are of little importance compared with the other rains.

The annual means of seventy stations give 2366·1 mm. (93·18 in.) as the annual average rainfall for the Philippines. The annual averages at the several stations range from 4597·6 mm. (181·05 in.) to 989·8 mm. (38·98 in.). The greatest fall is at Baguio, due to its elevation and the local topographical features; the least at Zamboanga. The annual extremes are very divergent. The heaviest annual fall at Baguio is 9038·3 mm. (355·91 in.) in 1911.

A feature of some interest is the summary of the weather of official holidays in Manila for the sixteen years. This is a step in advance of European official discussions.

University and Educational Intelligence.

LEEDS.—The James Edmondson Ackroyd memorial fellowship has been awarded to Mr. F. W. Dry, who will undertake a research on the comparative anatomy, histology, and pigmentation of mammalian hair as a basis for breeding and other experiments. The value of the fellowship is 300*l.* per annum, renewable for a period of three years.

MANCHESTER.—Mr. J. M. Nuttall, senior lecturer in physics, has been appointed assistant director of the physical laboratories, and Mr. D. C. Henry lecturer in chemistry.

Mr. A. J. Hailwood has been awarded the Moseley memorial prize in physics.

THE Berlin correspondent of the *Times* announces that Prof. Walter Nernst has been elected Rector of the Berlin University.

DR. LIVINGSTON FARRAND has accepted election to the presidency of Cornell University in succession to Dr. J. G. Schurman, recently appointed American Minister to China. After graduating at Princeton in 1888 and at the Columbia College of Physicians and Surgeons in 1891, Dr. Farrand spent two years in study at Cambridge and Berlin. From 1893 to 1914 he was connected with Columbia University, first as instructor in psychology and later as professor of anthropology. He was president of Colorado University from 1914 until after the armistice, when he joined the American Red Cross. In 1917 and 1918 he directed the anti-tuberculosis work of the International Health Board in France. Dr. Farrand was at one time editor of the American *Journal of Public Health*, and has contributed largely to psychological and anthropological publications. In 1904 he published a study of the Indian population and physical geography of North America entitled "Basis of American History."

THE Roll of War Service of the University of London Officers Training Corps has been published by the Military Education Committee of the University. The first section, devoted to the roll of the fallen, contains the names and other particulars of 665 officers who were members or former members of the contingent. Section ii. records 1726 honours and distinctions awarded to 1068 officers. The roll of war service forming the third section gives particulars of 4276 officers and former officers and cadets of the contingent who served as officers in the war. The appendices contain statistical and historical information. Of the 4218 former cadets who served as officers during the war 1579 were first enrolled in the contingent before the war, the remainder (2639) during the war, but only 202 obtained their commissions before the war. The colleges of the University contributing the largest number of cadets are University College, 558; King's College, 484; Imperial College, 471; Guy's Hospital, 235; and St. Bartholomew's Hospital, 230. The illustrations include portraits of the late Lt.-Col. A. G. E. Egerton, Coldstream Guards, first Adjutant 1909–13, and the five former cadets who were awarded the V.C. The volume is published by the Military Education Committee of the University of London at 46 Russell Square, London,

W.C.1, at 1 guinea, packing and postage 1s. extra; half leather binding $1\frac{1}{2}$ guineas, postage extra; and full leather binding 2 guineas, postage extra.

PROF. EINSTEIN's main object in recently visiting America was to meet the Jewish community of the United States in order to enlist its support for the proposed University of Jerusalem. The foundation-stones of this University were laid in 1918, and preparations are being made to erect an institution worthy of the noblest ideals of modern knowledge. It is proposed to commence with physical and chemical departments, a medical faculty, an arts faculty, departments of law and commerce, and a Jewish faculty. The object of the promoters is to make the institution serve the interests of the Palestinian population as well as those of general culture. The University will be up to date in equipment and representative of the highest scholarship in each department: the association with the institution of men like Einstein, Wassermann, Bergson, Alexander, Lord Rothschild, etc., makes this perfectly clear. The University will be in no sense exclusive. So far as possible, Hebrew will be the medium of instruction, this being the language spoken by the Jews of Palestine, but it need scarcely be said that religious and racial tests will be unknown. Mr. C. Crossland, Director of the Fishery Service, Sudan Government, writes to us to express the fear that the University will be Jewish in a clerical sense, but we believe this need not be entertained for a moment, because Jews all over the world, and especially in Palestine, are absolutely opposed to any form of clericalism in social, political, or cultural life. The University of Jerusalem will be the only real university for a considerable section of the Orient, and it is to be hoped that it will become a great centre of culture for the Near East, acting as a link between the East and West, and thus helping to encourage feelings of friendship and co-operation between the representatives of the great civilisations of the past and of the modern world. Of course, as regards methods of teaching and research the University will be modelled entirely on European and American standards. The outcome of Prof. Einstein's visit is that the medical faculty of the University is now assured, and we can expect in the near future to have this faculty established in a country where the combating of disease is of particular importance. Other faculties and departments will follow as the means are obtained for them.

THE RIGHT HON. VISCOUNT HALDANE delivered an address on November 9 last before the Old Students' Association of the Royal College of Science, South Kensington, dealing with the subject of the nationalisation of the universities. The address has recently been issued in pamphlet form by H.M. Stationery Office. The title, as Lord Haldane observes, "is somewhat of a paradox, so far as I am concerned," since he proceeds to declare his unrelenting opposition to any suggestion that the universities of the United Kingdom should come under the control of any State Department. He submits that the most vital element in a university is that of an atmosphere "which in itself is the most excellent of things, and would be as difficult as it is rare were it not for that divine spark in the human soul which means that those who are gifted need but little to bring them to devote their whole energies to concentration on the highest ideas." That atmosphere no State Department can produce. Nevertheless, the State as representing the nation must have a care for the abiding well-being of the people. The highest education, that offered by the universities, touches, after all, but a fraction of the people. Not one in ten of the population get any education at all after they leave school at the age of fourteen, and not one in a thousand get the advantage of the higher education of the universities. The problem is how to bring higher education to bear upon the democracy. One crucial difficulty is the cost, only a fraction of which, about 28 per cent., is met by the fees which well-to-do parents vainly imagine represent the real cost of the education which their sons and daughters receive. Apart from the endowments of past benefactors, the balance must be found by the gifts of the benevolent, which represents in the United Kingdom less than half a million sterling annually against the five millions contributed in the United States. The rest of the expenditure must be met from public sources, either from the rates or from the Exchequer, but the universities must be left free as to the means and methods which they employ in order to realise their obligations to the community, which are not only to train duly prepared students for their various faculties, humanistic and scientific, but also to undertake extra-mural work such as the Workers' Educational Association demands.

THE University of Bristol has issued a striking and beautifully illustrated appeal with the view of raising, under the novel form of "a group scheme," a five-year million fund, the participants in which may spread their contributions over a period of five years. The appeal is headed "The First Line of National Defence," as, indeed, rightly considered, a university significantly is. Already more than one million pounds sterling has been contributed in money, land, and buildings, chiefly by the inhabitants of Bristol, and notably by the Wills family, and now the University owns 19 acres of land within the city area, upon which its various fine buildings have been erected or are in course of erection. The University obtained its charter in 1909, and its course of instruction for degrees includes the customary faculties of arts, science, medicine, and engineering, inclusive also of agriculture and theology, together with many forms of extra-mural activities dealing with adult education. It is specially devoted to research in the various faculties. More endowed chairs and an increased staff of lecturers are needed, together with money for the establishment of fellowships, for departmental libraries, for equipment, and for research. One thousand two hundred full-time students and more than 1000 part-time students are in attendance, and the demand will grow as facilities for secondary education are increased and developed. The area embraced within the operations of this "University of the West" extends from the Cotswolds throughout the four south-western counties to Land's End. It is confidently to be hoped that within this area there may be found, not only on the part of private benefactors, but also on that of the local authorities, an eager willingness to support the efforts which the Council of the University is making to bring within the reach of the inhabitants of the four counties the highest possible facilities of learning and research in all departments of knowledge. The Treasury grant is to be raised in 1922 from one million to a million and a half sterling, and the University of Bristol can participate in it in proportion to the amount publicly subscribed. All the universities of the kingdom are in like straits for means of development, and it is worth while in this connection to direct attention to the munificence displayed in the United States by private persons, who gave in one year, 1917–18, in support of the universities and colleges of that country, nearly 5,500,000*l.*, whilst benefactions to such institutions in the United Kingdom amounted in the three years, 1916–19, to only 1,192,000*l.*

Calendar of Scientific Pioneers.

August 5, 1872. Charles Eugène Delaunay died.—Known principally for his work on the theory of the moon, Delaunay in 1867 succeeded Poncelet in the chair of experimental physics in the Sorbonne, and in 1870 was made director of the Paris Observatory. He met his death by drowning off Cherbourg.

August 6, 1879. Johann von Lamont died.—Though a native of Scotland, Lamont spent his life in Germany. Like Gauss, Hansteen, and Sabine, he was a pioneer worker in terrestrial magnetism, and in 1851 discovered a decennial period in the daily range of magnetical declination and earth currents. He directed the Bogenhausen Observatory, near Munich, and catalogued 34,674 stars.

August 7, 1848. Jöns Jakob Berzelius died.—The contemporary of Dalton, Davy, and Gay-Lussac, Berzelius occupied a pre-eminent position among chemists. He discovered cerium, selenium, and thorium, isolated silicon, zirconium, and tantalum, was a founder of electro-chemistry, and by his work on atomic weights furnished chemists with a set of exact constants of great importance. He was secretary and president of the Swedish Academy of Sciences.

August 7, 1898. James Hall died.—One of the most distinguished of American geologists, Hall for sixty-two years was connected with the Geological Survey of New York, and made valuable researches of the palæozoic invertebrata of that State.

August 7, 1912. François Alphonse Forel died.—Professor of anatomy and physiology at Lausanne, Forel was best known for his researches in limnology, and especially for his study of the seiches of Lake Geneva.

August 8, 1897. Victor Meyer died.—From Göttingen Meyer in 1889 went to Heidelberg as successor to Bunsen. He discovered thiophen, introduced a new method of determining vapour densities at high temperatures, and made investigations in stereochemistry.

August 8, 1919. Ernst Heinrich Haeckel died.—Professor of zoology at Jena for more than forty years, Haeckel was the first German biologist to make evolution the leading conception of biology. A prolific writer, his "Natural History of Creation" appeared in 1868, and his "Riddle of the Universe," containing his well-known monistic views, in 1899.

August 9, 1899. Sir Edward Frankland died.—The first professor of chemistry in Owens College, Manchester, Frankland afterwards succeeded Hofmann at the Royal School of Mines. His investigation of the laws of the formation of chemical compounds led to the theory of valency, and in applied chemistry he did very important work in connection with water-supply and the pollution of rivers. He received the Copley medal in 1894, and in 1897 was knighted.

August 10, 1802. Franz Maria Ulric Theodore Aepinus died.—Aepinus was born in 1724, and became mathematical tutor to the Russian Royal Family. Among physicists he is known as the author of "Tentamen Theoriæ Electricitatis et Magnetismi," 1759, the first systematic attempt to apply mathematics to these subjects.

August 10, 1915. Henry Gwyn Jeffreys Moseley died.—A graduate of Trinity College, Oxford, Moseley by a systematic determination of the X-ray spectra of many of the elements was led to the discovery that the properties of an element are defined by its atomic number, giving rise to "Moseley's numbers," which are recognised to be of fundamental importance. He was killed in action at Suvla, on the Gallipoli Peninsula, at the age of twenty-seven. E. C. S.

Societies and Academies.

PARIS.

Academy of Sciences, July 11.—M. Georges Lemoine in the chair.—C. **Moureu**: The second conference of the International Union of Pure and Applied Chemistry.—S. **Carrus**: Research on triply orthogonal systems.—M. **Alayrac**: The movement of a solid in a resistant medium. Some of the results in a recent communication by the author had been anticipated by M. Dulac.—MM. C. **Nordmann** and **Le Morvan**: The determination of the effective temperatures of some stars and their colour index. The value of the "colour index" of stars can be determined by the authors' method of colour photometry. This method results from two homogeneous measurements, and avoids all the causes of error and uncertainty due to the comparison of a magnitude determined separately by sight and by photography.—A. **Lafay**: The direct measurement of the mobilities of electrified particles in gases.—D. **Coster**: The fine structure of the series of X-rays.—A. **Marcelin**: The superficial extension of soluble or volatile bodies. Studies on the displacement of particles floating on water by the changes in surface tension caused by the introduction of a piece of camphor, menthol, and *iso*butylcamphol.—M. **Fric**: Contribution to the study of the stability of nitrocellulose powders. The changes in composition caused by ultra-violet light in solutions of the powders in acetone were followed by the resulting changes in the viscosity of the solutions.—P. **Lebeau** and M. **Picon**: The action of sodammonium on diphenylmethane, fluorene, and indene. Dimethylfluorene. Sodammonium reacts with indene and fluorene, giving substituted sodium derivatives, and at the same time hydrogen is added to a certain proportion of the hydrocarbon. Indene gave 50 per cent. of the dihydride.—MM. **Pariselle** and **Simon**: Syntheses of tertiary alcohols, starting with methylethylketone.—L. **Longchambon**: Rotatory power in crystallised media.—P. **Fallot** and H. **Termier**: The vertical extension of the marl facies containing pyritic Cephalopods in the Island of Ibiza.—J. **Mascart**: The method of working out averages in meteorology. A discussion of some of the difficulties underlying the problem of taking true meteorological averages.—P. **Schereschewsky**: The foundations of the rational classification of clouds.—J. **Politis**: The *rôle* of the chondriome in the formation of essential oils in plants.—M. **Molliard**: The function of potassium in the chemical actions and the reproductive functions of the fungi.—MM. **Cluzet** and **Bonnamour**: The electrocardiographic study of the arrest of the heart in electrocution.—H. **Marcelet**: The hydrogenation of some marine animal oils. The oils from eight species of fish were treated with hydrogen in presence of nickel carbonate as catalyst at a temperature of 250° C. The changes in the iodine figure and melting point are given in each case; all the oils lost their disagreeable smell under the treatment.—Mme. A. **Drzewina** and G. **Bohn**: The phenomena of autoprotection and autodestruction in aquatic animals.—A. **Trillat** and R. **Kaneko**: Activity of infection by the air. Studies on the infection of mice by the Danysz paratyphoid organism and by pneumococcus. Of the various methods compared, the infection by bacterial fogs proved to be the most delicate, positive results being obtained by much smaller weights of bacterial emulsion when carried by air than when introduced by subcutaneous injection, with food, etc.—H. **Frossard**: The action of the orbiculo-costo-diaphragmatic reflex on the sympathetic and parasympathetic systems.

July 18.—M. Georges Lemoine in the chair.—The president announced the death of M. Gabriel Lippmann.—A. **Haller** and Mme. **Ramart-Lucas**: The two dextrorotatory methylallylcamphocarbonates, the three propanol-2-camphocarbonolides, and the 2-camphopropanol derived from them.—P. A. **Dangeard**: The structure of the plant-cell in its relations with the theory of the chondriome. A summary of the author's work on this subject since 1918, and an account of his system of nomenclature.—M. **Janet**: The characteristics of certain partial differential systems comprising as many equations as unknown functions.—A. **Denjoy**: A mode of progressive integration and the corresponding characters of integrability.—J. **Andrade**: Possibilities of new types of chronometer.—L. **de Karasinski**: The resistance of materials.—E. **Rengade** and E. **Desvignes**: An arrangement for testing the hardness of refractory materials at a high temperature. The method employed is a modification of the Brinell test, in which the ball is replaced by a cone of Acheson graphite. The specimens were heated in an electric furnace and the temperature was determined by an optical pyrometer. The results of numerous observations carried out on clay and bauxite bricks at temperatures between 1150° C. and 1470° C. are given in a diagram. The bricks show a gradual softening, as has been already mentioned by MM. Le Chatelier and Bogitch. Silica bricks behave differently; up to about 1600° C. they give no imprint, then the brick breaks up suddenly.—A. **Dauvillier** and L. **de Broglie**: The distribution of the electrons in the heavy atoms.—A. **Debierne**: The diffraction of the X-rays by liquids.—H. **Pélabon**: The resistance of thallium sulphide and selenide. The resistance of the compounds Tl_2Se and Tl_2S in the solid state varies with their previous thermal treatment. The specific resistance varies with the temperature according to a law which remains the same, but the resistance is not determined when the temperature is known. In both cases there is an abrupt change in the resistance on melting.—P. **Pascal**: The magnetic properties of the alkaline earth metals in combination.—H. **Weiss** and P. **Lafitte**: The interpenetration of solids. An extension of experiments already described with zinc and copper to other pairs of metals.—E. **Decarrière**: The *rôle* of the gaseous impurities in the catalytic oxidation of ammonia gas. The results with traces of sulphuretted hydrogen have been given in a previous communication. Figures for acetylene are now given, and it is shown that the effect of this gas as impurity is more serious than that of sulphuretted hydrogen, since the lowering of the yield increases with the total amount of acetylene which has passed the catalyst, and is not simply dependent on the proportion actually present at any given time. If both sulphuretted hydrogen and acetylene are present as impurities in the ammonia, as is the case with ammonia prepared from commercial cyanamide, the former has a protective action and the injurious effect of the acetylene is in great part neutralised.—L. **Hackspill** and E. **Botolfsen**: The preparation of calcium carbide by calcium ammonium and acetylene. Pure calcium carbide is not obtained by Moissan's method, the decomposition at 150° C. of the compound $C_2Ca{\cdot}C_2H_2{\cdot}4NH_3$. The calcium carbide formed is very impure, and contains cyanamide, calcium cyanide, and free carbon.—C. D. **Zenghelis**: A new reaction of ammonia. A concentrated solution of silver nitrate in formaldehyde (formol) freshly made gives a mirror of metallic silver with traces of ammonia. The reaction was obtained with 0·00034 milligram of ammonia, and ammonia has been detected in potable water in a case where no indication was given by the Nessler reagent.—M. **Picon**: A new method of preparing the sodium derivatives of the true acetylene hydrocarbons. The acetylene is treated with sodium amide in liquid ammonia; the products are pure and the yields are high.—A. and J. **Pictet**: The polymerisation of the glucosanes.—A. **Mailhe**: The nitro- and amido-derivatives of methylethylbenzene.—L. **Doncieux**: An ancient passage of the pre-Wurmian Rhone through the plateau of Clarafond, Haute-Savoie.—J. **Savornin**: Extension of the continental Aquitanian to Morocco.—H. **Ricôme**: The causes of the inverse orientation of the root and stem.—M. **St. Jonesco**: The existence of anthocyanidines in the free state in the fruits of *Ruscus aculeatus* and *Solanum dulcamara*.—P. **Benoit**: The female gonophores of *Tubularia mesembryanthemum*.—P. **Wintrebert**: The existence of a transitory nervous dualism at the commencement of the neuro-muscular connection in Selacians.—G. **Bertrand** and R. **Vladesco**: The probable intervention of zinc in the phenomena of fertilisation in the animal vertebrates. In man the prostate gland is richer in zinc than the testicles, and its proportion of zinc exceeds that found in any of the other organs of the body. Similar ratios were found for the ox, but in the pig the seminal vesicles possess the maximum zinc content. It would appear that zinc plays an important part in the phenomena of reproduction in vertebrates.—E. **Aubel**: The action of the pyocyanic bacillus on asparagin. Among the reaction products malic, formic, fumaric, and propionic acids were identified.—P. **Courmont**, A. **Rochain**, and F. **Laupin**: The disappearance of pathogenic germs in the course of the purification of sewage by activated sludge. After six hours' treatment pathogenic organisms of the typhoid-paratyphoid group are nearly always present in the effluent; the cholera vibrion disappears.—F. **Diénert**: Concerning activated sludge. A study of the influence exercised by carbolic acid on the fermentations caused by activated sludge.—MM. **Desgrez**, **Guillemard**, and **Hemmerdinger**: The fixation of carbon monoxide diluted and carried by an air-current. An attempt to find a reagent suitable for the absorption of small proportions of carbon monoxide in a gas-mask. The best results were obtained by using pumice (27) saturated with a mixture of iodic anhydride (9) and sulphuric acid (2·5).

Ottawa.

Royal Society of Canada, May 18–20.—Presidential address, Prof. J. C. **Fields**: Division in relation to the algebraic numbers.—Prof. A. S. **Eve**: Ionisation potential and the size of the atom.—Prof. A. S. **Eve** and E. S. **Biehler**: Detection of variation in electric earth-currents by coil and galvanometer.—Miss V. **Douglas** and Dr. J. A. **Gray**: The effective range of β-rays.—Dr. J. A. **Gray**: The velocity of sound in air and soil. Properties of X-rays excited by β-rays. The absorption of γ-rays. A note on the examination of materials by X-rays.—Dr. A N. **Shaw** and L. S. **Smith**: The transmission of heat through the thin boundary films of air or of water at the surface of glass.—Dr. E. H. **Archibald**, C. E. **Stone**, and E. M. **White**: The viscosity of ether at low temperatures, and solution of acetic acid in liquid hydrogen bromide.—Dr. W. F. **Seyer**: Preliminary report on the lubricating properties of the different series of hydrocarbons.—Dr. D. F. **Steadman**: An automatic mercury pump.—W. A. **Hardy**: Some results of the destructive distillation of British Columbia alder and Douglas fir.—Dr. J. H. L. **Johnstone**: The variation of the "emanating power" of certain uranium minerals with temperature, and a new secondary radium emanation standard.—C. A. **Mackay**: The effect of thermo-luminescence on electrical conductivity.—J. **Patterson**: The anemometer factor. Pilot-balloon methods in

Canada.—Dr. L. V. **King**: Some new formulæ for the direct numerical calculation of the coefficient of mutual induction of coaxial circles. A new high-frequency vibration galvanometer. The photographic recording and measurement of radio-telegraph signals. A new lecture-room illustration of atomic models.—Prof. J. C. **McLennan**: The refractive indices of metallic vapours.—W. W. **Shaver**: The absorption spectra of liquid and gaseous oxygen.—Prof. J. C. **McLennan** and P. **Lowe**: The structure of the Balmer series lines of hydrogen.—Prof. J. C. **McLennan** and P. A. **Petrie**: The spectra of helium, hydrogen, and carbon in the extreme ultra-violet.—Prof. J. C. **McLennan**: The liquefaction of hydrogen.—W. A. **Lawrence**: Nitrophthalic anhydrides and acetylaminophthalic anhydrides with toluene and aluminium chlorides.—H. N. **Stephens**: Bromophthalic anhydrides with benzene and aluminium chloride.—N. A. **Clark**: The effect of certain chemicals on the rate of reproduction of yeast.—Prof. J. B. **Ferguson** and G. A. **Williams**: The passage of hydrogen and of helium through silica tubes.—W. B. **Leaf**: The action of methyl-green on yeast.—K. L. **Wismer**: Pressure-volume relations of superheated liquids.—W. H. **Martin**: Scattering of light by dust-free liquids.—Prof. F. B. **Kenrick**: Note on Wolski's paper on optically empty liquids.—Prof. J. B. **Ferguson**: Re-determination of the melting point of sodium chloride.—Prof. W. L. **Miller**: Researches in physical and organic chemistry carried out in the chemical laboratory of the University of Toronto.—Dr. J. C. **Glashan**: The reduction of the circulants to polynomial form with applications to the circulants of the 7th and 11th degrees.—Prof. A. H. S. **Gillson**: The gravitation potential of an anchor ring. Some tidal problems.—Prof. E. F. **Burton** and Miss E. S. **Bishop**: Law of distribution of particles in colloidal solutions.—S. **McLean**: Production of heat during charcoal absorption.—Prof. E. F. **Burton** and E. D. **McInnes**: The relation between coagulative power of electrolytes and concentration of colloidal solutions.—Dr. J. S. **Plaskett**: The radial velocities of 570 stars. The orbit and dimensions of TV Cassiopeiæ. The temperature control of the stellar spectrograph.—W. E. **Harper**: The orbital elements of the brighter components of Boss 497. The orbits of spectroscopic components of Boss 4622.—H. H. **Plaskett**: The intensity distribution in typical stellar spectra.—Dr. S. D. **Killam**: The solution of plane triangles by nomographic charts.—Dr. C. T. **Sullivan**: Note on the geometrical equivalence of certain invariants.—Dr. W. B. **Dawson**. The interpolation of breaks in tide curves for recording gauges.—Dr. F. T. **Shutt** and Miss A. H. **Burwash**: The vertical movement of alkali under irrigation in heavy clay soils. Notes on the nature of burn-outs.—Prof. H. F. **Dawes**: Reversible pendulum.—Prof. A. L. **Hughes**: Characteristic X-rays from boron.—Prof. J. **Satterly**: A new experiment in vibration.—Prof. J. C. **McLennan**: Note on the spectrum of potassium. Note on infra-red spectroscopy.—H. J. C. **Ireton**: Selected radiation emitted by specially excited mercury atoms.

University Finance.

THE problem of university finance is not a simple one, and the solution is not yet. Apart from endowments, which in this country are relatively small, the three main sources of income are students' fees, Parliamentary grants, and grants from local authorities, and these three bear no fixed relation to one another. Students' fees vary according to time and place; the Parliamentary grant, administered by the University Grants Committee, seems to be allocated according to no definite principle; and the local authorities may or may not contribute to the maintenance of the universities, and where they do contribute their subventions from the rates are by no means uniform in amount. Even in normal years the fluctuating character of the income makes the task of financing a university not a light one, while in abnormal times the task becomes one of difficulty and embarrassment. Under such conditions the marvel is that so many able business men have been found ready and willing in an honorary capacity to give their time and energy to help in directing the financial affairs of our universities. That they do so speaks much for the hold which higher learning has upon a valued and important section of the community, but such interest ought not to be looked upon as a justification of the system, or rather lack of system, of finance which exists at present.

One of the main principles which should govern university finance is that the income should be stable. There should be sufficient for necessary needs, and something over for development and expansion. Now it is no exaggeration to say that in most, if not all, of the universities at present this fundamental principle is more honoured in the breach than in the observance. Very few can budget with reasonable certainty for several years ahead, yet they most certainly ought to be able to do so if they are to fulfil the function for which they were founded. For one thing there should be reasonable assurance of reasonable salaries. But since in general the salary bill of the teachers is rather more than half the total expenditure, it is obvious that a fluctuating income makes it extremely difficult to give that assurance. The teachers may lament their hard lot, and it has been extremely hard with many, but if there is no certainty as to income from year to year there is little hope for a reasonable and proper amelioration. In view of such facts, it was well that university finance should be discussed at the Congress of the Universities of the Empire held recently at Oxford.

The subject was opened by Sir J. A. Ewing and Dr. Adami in two interesting and able papers. The former gave a comparative statistical survey of the larger universities, arriving at the conclusion that the average cost "per head," in the fourteen university institutions selected by him, amounted to approximately 65*l*., and that of this sum 34*l*. was spent on salaries and superannuation, and about 6*l*. on administration. These figures, though they must be taken with some reserve, are interesting, but do not "cut much ice." Perhaps it is more helpful to learn that 25*l*. of the 65*l*. is paid by the student, and 20*l*. comes from Parliamentary grants, for then we gather that the student pays rather more than one-third of the cost of his education, while the Government pays rather less than one-third. But what further inferences we are to draw from these statements the learned principal of Edinburgh University omits to say. Incidentally, however, there emerge two facts which some of our more observing readers might have anticipated. The first is that among universities the economic advantage of large-scale working holds just as in ordinary business concerns; and the second, that the group of three Scottish universities is run at a lower cost per head than any of the other groups. In view of this it would have been interesting, and no

doubt instructive, had the statistics contained a comparative table of salaries paid in the various universities or groups of universities quoted by Sir J. A. Ewing.

Turning to the paper read by the vice-chancellor of Liverpool University, one is struck by the clear exposition of the subject, the principles enunciated, and the policy suggested. The aggregate income of twenty-one institutions of university rank in Great Britain has been carefully analysed. From the figures given we find that students' fees amount to 39·7 per cent. of the total income; Parliamentary grants, 36·5 per cent.; and local authority grants, *plus* income from endowments, 23·7 per cent. As the aggregate income is more than 200,000*l*. short of the estimated expenditure, Dr. Adami suggests that the prospective deficit should be met by additional grants from local sources. He thinks that the contribution from the city in which the university is situated should be at least one penny in the pound, and that the other authorities, town and county, of the district served by the university should contribute at least one halfpenny in the pound. The only criticism we have to offer upon this is that Dr. Adami is too modest in his demands. There seems to be no sound reason why the whole of the local authorities in the Kingdom, urban and rural, should not contribute a uniform rate of one penny in the pound. The universities are not local, but national. Undoubtedly a penny rate for the whole country would ensure a greater measure of stability, and would go far to solve the problem of university finance.

Regarding the question of salaries, Dr. Adami quotes extensively and effectively from the memorandum prepared by the Interim Committee of the Conference of University Authorities and the Association of University Teachers. The scale of salaries suggested by the committee, and afterwards adopted by the conference, is given, as is also the estimated additional income required to put the scale into immediate operation in England and Wales. A rough estimate places the sum at about 350,000*l*.

On the subject of the superannuation of university teachers Dr. Adami is on firm ground when he says that the matter cannot rest where it is at present. The recent grant of 500,000*l*. from the Treasury (acceptable as it is) for the purpose of augmenting the superannuation allowances of certain of the senior members of the staffs of the universities is not only totally inadequate for its ostensible purpose, but also subjects those university teachers who have seen teaching in schools or technical institutions outside the university to differential treatment of quite an unjustifiable character. At present a schoolmaster of standing cannot accept a position in the university without a loss of pension benefits. This rift between the universities and the schools and technical and training colleges outside the universities cannot be allowed to continue. Anyone who has the best interests of the universities at heart will agree with Dr. Adami that "some method must be discovered whereby years spent in one service are duly recognised in the other for pension purposes." We have on more than one occasion expressed the same opinion in these columns.

One other point. No discussion of university finance where Parliamentary grants are involved would be complete without reference to the relation of the State to the university. There are some who see in the growing financial intimacy between the State and the university a threat to the autonomy of the latter. Whether this opinion is shared by our readers or not, we believe that the freedom of the university is so vital for its efficiency and its highest development that it is the duty of every university teacher to guard jealously this most valuable possession, and we believe they will not fail in this duty. It was natural and fitting, therefore, that the subject should come up for discussion at the Oxford congress, and, considering the issues involved, it is perhaps not a matter for surprise that it gave rise to one of the outstanding incidents of the congress—a brilliant speech by Sir Michael Sadler on the freedom of the university.

The Bible.

The Bible: Its Nature and Inspiration. By Edward Grubb. (Published for the Woodbrooke Extension Committee.) Pp. 247. (London: The Swarthmore Press, Ltd., 1920.) 2*s*. 6*d*. net.

IN this handy little paper-covered volume Mr. Grubb gives us a most readable and interesting historical account of the Bible and of our knowledge of its growth and development. As the advertisement on the cover justly says:—

"This . . . book explains what the Bible really is, and why Christians value it above all other books. Many suppose that if the Bible is not literally true, from beginning to end, it is of no use at all. That is quite unreasonable. The presence of human imperfection in the work of

the men who wrote the Bible is no proof whatever that they had not a real and living message from God to the people for whom they wrote—and for us, if we will take the trouble to understand it."

Mr. Grubb is a believing Christian, and writes for Christians with a breadth of view that is a tribute to the writer's common-sense and humanity (in the higher sense of the word). One wishes one could say as much for many so-called "Rationalistic" writers, some of whom have been more bigoted and more intolerant, more narrow and uninformed, than the worst Roman "cagot" or Calvinistic heresy-hunter that ever lived. However, these professional anti-Christian fanatics are nowadays almost a thing of the past. A few who still survive here and there are mere relics of the mid-Victorian age who do not count. We are talking of Britain, of course; in France the species still lives and flourishes.

Nothing has contributed more to the rout of the old-fashioned Freethinkers than the discoveries that have been made since the 'seventies in the realm of ancient Oriental history and anthropology, which have shown that the Old Testament was not, as those of our grandfathers who considered themselves enlightened supposed, a collection of baseless fables, but real history, sometimes in the guise of legend, but more often in that of genuine copies of ancient annals. The cuneiform discoveries of Rawlinson and George Smith, the recovery of the ancient history of Egypt to the confusion of the supposedly intelligent but really extremely credulous Sir George Cornewall Lewis, the finding of the Moabite Stone, and the critical study of the text of the historical books of the Old Testament, have all shown that in the Bible we are dealing with real history and with tradition based upon facts. They show also that, in the obvious myths, such as those of the Creation and the Deluge, we have before us extraordinarily interesting accounts akin to the cosmogonical myths of the Babylonians, pointing to the origin of Hebrew civilisation. But in the relief which these discoveries gave to those Christians who demanded "belief in" the Bible (a phrase that meant everything to them, though to the more instructed it might mean anything or nothing) as a condition of their faith in Christianity, and in the triumph which the godly felt had been vouchsafed to them over the vain imaginings of the ungodly, the new discoveries were hailed as "proving the Bible"—as showing irrefragably that the Biblical books were all "inspired" truth, and that Moses wrote the Pentateuch after all. One sees that this would be of great interest and importance to a professing Jew, but one is puzzled to know how, even if Moses did not "write the Pentateuch," the fact could affect the faith of a Christian. A *new* law was given to the world by Our Lord, based, indeed, on the traditional beliefs and teachings of His people, the Jews, but owing nothing of its authority to them. Some Christians, however, of the Reformed Churches have always been more Jew than Christian!

There is, indeed, little fact behind the idea which one often meets that archæological discovery has "proved" the literal truth of the whole of the Old Testament, and incidentally "shown that Darwin was all wrong" (a very prevalent idea). Similarly, as little fact supports the idea of the old-fashioned Rationalists that the Bible was from beginning to end an invention of designing priests. Archæological discovery has certainly "proved the truth" of the Old Testament, but not in the literal sense which alone is comprehended by the simple-minded. Both the Tale of Troy and the Arthurian Legend are doubtless "true" in that they are indubitably based on fact, and that is what archæological discovery shows us with regard, for example, to the books of Joshua and Judges. "Kings" and "Chronicles" are annals; they are (as we can see by comparison with contemporary historical documents, Egyptian and Assyrian, as well as from internal evidence) more trustworthy than the others, as the Anglo-Saxon Chronicle may be more trustworthy than Giraldus Cambrensis or Geoffrey of Monmouth; they are on the same level as such chroniclers, no less, but also no more. The Bible must be looked at as objectively as any other scripture; and if we study it so, and also with reverence as the foundation of Christ's teaching, and as a Holy Book inspired by the Spirit of God, because it is the work of man, we shall understand many things that hitherto have been hid from us, and see clearly where formerly we were blind.

This is the position that Mr. Grubb holds in common with all enlightened Christians of to-day, whether English Catholic, Presbyterian, or Free. Rome still seems to affirm "verbal" inspiration officially. The English reformed branch of the Western Catholic Church, with its freedom won by the Reformation from the dead hand of ancient official pronouncements made in the days of ignorance, has during the last fifty years obtained for itself a reputation for freedom of discussion and scientific criticism of Biblical matters on the part of its learned divines even more honourable than that of its fellow Protestant Churches. Many of the greatest lights of the "Higher Criticism" have been English Churchmen, and obscurantist circles have often been scandalised by the fact.

Unhappily, one or two of the "Higher Critics" have gone much too far with their textual criticism, and honestly, but mistakenly, have invented a new Old Testament of their own imagining, and a very dull and uninspired thing at that. The text of the real Book is often obscure, and not seldom corrupt, so that it must be emended, but not so much so as to be a sort of Bacon-Shakespeare cryptogram which can be elucidated only by methods strongly reminiscent of Mrs. Gallup! The "Higher Criticism" does not connote this sort of fantasy; what it really is Mr. Grubb shows with both knowledge and skill. From his little book the interested reader can see just how far archæological discovery has confirmed the general historical character of the legendary and annalistic books of the Old Testament, and he will be able to realise what "textual criticism" means in the case of Hebrew manuscripts; the distinctions between the different schools of early Jewish religious writers that "wrote the Bible"—the Jahvist ("J"), the Elohist ("E"), and the Priestly ("P") writers—will be made clear to him. He will also be able to understand the fact of the various "strata" of Isaiah, which can be printed, if necessary, in different colours to distinguish them.

The Bible, treated scientifically and subjected to the same criticism as any other collection of ancient legends and poems, becomes extraordinarily interesting. If the sacred books of a religion cannot stand criticism, they are not worth much. The "Book of Mormon" cannot stand criticism; the Holy Bible can and does. Literal truth at all times and in all places is not the question. Christianity does not stand or fall by the "verbal inspiration" or literal "truth" of the Old Testament, but rests foursquare and secure on the teaching of its Founder as given to us in the New. He regarded the scriptures of His ancestors with the same reverence that we do, who seek out and study their origins and growth in order that we may the better understand the bases of our faith and so teach it *ad majorem Dei gloriam*. H. H.

Zoology for Medical Students.

An Introduction to Zoology. By Prof. C. H. O'Donoghue. Pp. x+501. (London: G. Bell and Sons, Ltd., 1920.) 16*s*. net.

THE object of this volume is to provide a text-book for the zoological portion of the syllabus in biology for the first examination for medical degrees of the University of London, and for the first examination of the Conjoint Examining Board in England.

For an introduction to zoology for medical students, the subjects discussed, the degree of fullness of treatment, and the order of their presentation are admirably suited. After a preliminary chapter, the frog is first treated as an introduction to anatomy, physiology, and histology; then follow accounts of two free-living and two parasitic Protozoa—Amœba and Paramæcium, Monocystis and the malaria parasite. A chapter is given to Hydra and Obelia, and another to the earthworm and Tænia, while the dogfish is treated at length. An account of the rabbit takes up nearly 100 pages, and this section includes—an excellent addition—descriptions of the skull of the dog, and of the brain and heart of the sheep. A chapter on histology and cytology follows, which deals mainly with cytology, including spermatogenesis and oogenesis; the section on embryology introduces the early development of Amphioxus and of the frog (which finds its place here instead of in the earlier chapters); while the chick and rabbit are treated more completely. A final chapter is devoted to evolution, variation, and heredity.

The present writer is convinced that such a course, beginning with a fairly full account of an animal that goes on four legs, the internal arrangements of which correspond in some degree with what the beginner already knows of his own body, and then working upwards from the Protozoa, is, as the author has found, the most satisfactory from the point of view of both teacher and student. The number of forms to be studied must be sufficiently large to serve as a basis for the wider appreciations and generalisations on the comprehension of which the value of the course to the medical student depends. Medicine is applied biology, and if the student does not grasp the fundamentals at this stage he will not do so from the specialised study of human anatomy and physiology at a later period. At the same time, as the author implies, the multiplication of types beyond what is strictly necessary to illustrate fundamental principles is to be deprecated as involving a study of unnecessary details. In the present state of the medical curriculum there is no excuse for presenting the ordinary student with a survey of the whole animal kingdom—a practice that perhaps still survives in places. A complete study of a few well-chosen forms, with similarly thorough laboratory work on those forms, is worth more for the purpose of giving an insight into biological principles—and infinitely more as a training in scientific method and thoroughness—than skimming over all or most of the phyla of Invertebrates and the classes, or even orders, of the Vertebrates.

A few criticisms of details are necessary. The account of the physiology of digestion is, quite

suitably, an account of mammalian digestion, but this should be stated; instead, it is said to be an account of the physiology of digestion in general. The respiratory movements in the frog are badly explained; if they took place as described, no air would ever be expelled to the exterior, and the animal would ultimately burst. Also the description of the frog's truncus arteriosus is not easy to follow, and there is no explanation of how its mechanism works, and no statement that the arterial arches contain blood of different degrees of oxygenation. The author appears to distinguish ague from malaria ("three distinct diseases, malaria and two kinds of ague"); while only the maximum recorded length (36 metres) is given for *Taenia saginata,* which is surely liable to mislead the student as to its usual dimensions.

The last chapter, which is so important, is too compressed; the subjects of the forty-two pages include evolution; variation, heredity, and selection in connection with the Darwinian theory; Mendelism; and palæontology as illustrated especially by the reptiles; while the topics of the evolution of sex and its meaning do not appear to find a place. Some of the figures introduced from Bourne's "Comparative Anatomy of Animals" have suffered considerably—*e.g.* those of the nephridium of the earthworm and of the skeleton of Scyllium; they are unworthy of a place in the book.

Errors which have been noted are as follows: A trochanter is a prominence, not a depression (p. 30); to say that membrane bones are "formed by bone tissue being laid down in a membrane" is neither adequate nor correct. Among misprints one might note "Calkin," "Bütchli," "Weissmann," "strobilla," "alteration" (of generations), "aborizations" (p. 95), "cœcum" and "stomodœum" for "cæcum" and "stomodæum," and "anistropic" (p. 42). "Pre-caval" contains an unnecessary hyphen, while in "sub-cutaneous" and "sub-clavian" it is more than unnecessary.

The author, in his preface, acknowledges his indebtedness to Profs. Dendy and Hill, especially to the latter, on whose lecture-notes parts of the book are more or less directly based.

The Analysis of Steel.

The Chemical Analysis of Steel-Works' Materials. By F. Ibbotson. Pp. viii + 296. (London: Longmans, Green, and Co., 1920.) 21s. net.

THE "Analysis of Steel-Works' Materials" of Brearley and Ibbotson has long enjoyed a reputation as a sound and trustworthy manual of the subject with which it deals, and its contents are familiar to most steel analysts. The revision of the work has been undertaken by one of the authors only, and advantage has been taken of the occasion to extend the treatment of steels, alloys, slags, etc., on the analytical side, and to gain space for such extensions by omitting the sections of the earlier work dealing with pyrometry and the use of the microscope. In the interval which has elapsed since the original publication many books on these two subjects have made their appearance, and their development has been so rapid that it has become undesirable to attempt their treatment in the course of a few short chapters in a work devoted mainly to a different branch of the subject. Mr. Ibbotson's experience of the analysis of steel-works' materials is exceptionally wide, and the methods which he describes have been in all cases personally tested and compared with alternative processes, so that the author may be accepted as a safe guide, especially in the difficult region of the analysis of high-speed tool steels and other complex alloys containing the rarer metals.

The separation of the rarer elements has been worked out with great care for the purposes of mineral analysis, and it is possible, by following somewhat laborious methods, to effect a complete separation of the metals contained in a mineral with a high degree of accuracy, as has been shown more particularly by American work on the composition of rocks. The analysis of complex steels, however, calls for processes which are rapid as well as accurate, since the results are usually required for commercial purposes within the shortest possible time. The high cost of the rarer alloy metals makes their exact estimation very important, whilst certain alloy steels are remarkably sensitive to minute variations in the proportions of the added elements, so that to devise methods which will yield, in the hands of the works chemist, results of the required accuracy in a reasonably short time is a task of some difficulty. The author lays great stress on accuracy, so that while his methods are not invariably the most rapid, they are such as can be trusted where a gain in speed might possibly be accompanied by a serious risk of error.

The work differs a little in its arrangement from most text-books on the subject. The opening chapter deals with certain reactions of a more or less general character, including the separation of iron from other metals, the reduction of solutions by nascent hydrogen by means of the Jones reductor, and the precipitation of chromium, molybdenum, tungsten, and vanadium by means

of mercurous nitrate. The succeeding chapters describe the estimation in turn of the elements which usually occur. The methods for the direct combustion of carbon are comparatively slow, and it would have been advantageous to add a description of the rapid methods, using small electrically heated tubes, which were devised during the war for the enormous number of shell steel samples which had to be analysed in the Admiralty and other laboratories. In such rapid methods soda lime is used with advantage in place of the more cumbrous potash bulbs. In the Volhard estimation of manganese the simple method of precipitation with zinc oxide and titration without removal of the iron, which is very convenient in the analysis of ferro-manganese, is not mentioned. The estimation of sulphur and phosphorus in steels, about which disputes are most frequent, is treated very thoroughly.

The analysis of ores, refractories, slags, fuels, and boiler waters is dealt with in later chapters. The section on slags suffers somewhat from its brevity, and many chemists would welcome a fuller account of this important subject. Thus in the analysis of basic slags no mention is made of the distinction between total and available phosphoric acid, on which the value of the slag so largely depends, and it would also have been well to include some account of the estimation of fluorine in such slags; the addition of fluorspar in the basic open-hearth process is frequently practised, and its effect is to convert a part of the phosphoric acid into an inert form.

Mr. Ibbotson's work may be confidently recommended to the analyst and student as a trustworthy guide to the subject by an author of ripe experience in the field in which he has worked so long.

Relativity and Gravitation.

Relativity: The Electron Theory and Gravitation. By E. Cunningham. Second edition. (Monographs on Physics.) Pp. vii + 148. (London: Longmans, Green, and Co., 1921.) 10*s.* 6*d.* net.

THE second edition of Mr. Cunningham's book, like the first, aims at presenting the problems of relativity in a form suitable for the general physicist. More than half the book deals with the special theory, giving the fullest account of the experimental side in any English book. This part is practically unchanged from the first edition—too little changed, for one would have liked to see the author's views on Majorana's experiments, which are not mentioned.

In discussing the general theory, he follows the historical order of development, commencing with Eötvös's experiment, which showed that the weights of two bodies of different constitution in the same gravitational field are proportional to their inertias within 5 parts in 10^8. From this he advances by a series of generalisations. First, light has inertia; if Eötvös's result is true for it, it must also have weight. Therefore it cannot travel in straight lines in a gravitational field. Therefore the differential ds, which is intimately related to the behaviour of light in the special theory, must, if it is still to maintain this relation to light, have a form in a gravitational field that takes the field into account. It has also a relation to the motion of a particle in the special theory; we knew already that it would have to be modified in form to maintain this in a gravitational field.

It is therefore assumed that the same form will still answer both purposes. Previously, again, the law of gravitation satisfied a condition that was unaltered by any displacement of the origin or rotation of the axes. Suppose, then, that the coefficients in the new ds satisfy a condition that is unaltered by any change in the co-ordinates used; the class of changes admitted is to be as wide as will permit some such condition to be satisfied. This leads at once to the irrelevance of the mesh system, and appears to the reviewer to be the best reason yet advanced for attributing to this principle any appreciable prior probability.

The crucial tests of the theory are described, and a chapter is devoted to Weyl's theory of electric and magnetic forces. The book is well arranged and written. Enough does not seem to be made, however, of the crucial tests. For anything that any professed exponent of the theory has said, there might be a million other theories, all as probable as Einstein's, which would give the same predictions. It may be pointed out that on p. 114 the assumptions given are not enough to ensure that the coefficient of $drdt$ shall be zero, which is assumed a few lines later; that in the footnote on p. 107 it is implied that a purely imaginary quantity can have a true minimum; and on p. 120 that the mere fact that the resultant velocity of an object is known is not enough to determine its path. But in the main the book is a careful and sound analysis, and can be recommended to all students of the theory.

H. J.

Our Bookshelf.

The North American Species of Drosophila. By A. H. Sturtevant. (Publication No. 301.) Pp. iv+150+3 plates. (Washington: The Carnegie Institution of Washington, 1921.)

A systematic account of the North American species of Drosophila and related genera, which includes many new species from collections made in various parts of the continent, will be found in this volume. One of the chief features of interest in such a monograph lies in a comparison of the systematic differences distinguishing species with those distinguishing mutants. In the latter part of the work this subject is discussed. The species of Drosophila, although often closely alike in appearance, so that only intensive study has succeeded in separating them, are extraordinarily difficult to cross. This applies not only to those having different chromosome groups, which no one has yet succeeded in crossing, but also to those in which the chromosomes are alike.

Dr. Sturtevant points out that both species and mutants may differ from each other in such features as eye-colour, wing-shape, abdominal pattern, and size and shape of eyes; but in studying specific differences it is "often necessary to examine minute characters, such as wing-vein indices or the relative sizes of certain bristles, that are seldom examined in material bred for genetic purposes." Many of the mutant characters are, however, similar to those observed between species. The general impression is received that specific differences and mutations may both be found in practically any character studied. The species usually differ slightly in innumerable characters, while mutants often differ strikingly in a few. This does not indicate that specific and mutational characters are different in kind, but that only the smaller mutations, by upsetting less the economy of the species, usually survive as specific differences. R. R. G.

Introduction to General Chemistry. By Prof. H. Copaux. Translated by Dr. H. Leffmann. Pp. x+195. (Philadelphia: P. Blakiston's Son and Co., 1920.) 2.00 dollars net.

In its translation into "standard English" (*vide* preface) Prof. Copaux's excellent little book has suffered considerably. It may be that "chlorin," "sulfur dioxid," and "do not have" are "standard" English, but in many cases the translator does not appear to have understood what he was doing, and the result (*e.g.* p. 55) is quite unintelligible. There are numerous minor inaccuracies in translation, and others are added in the footnotes contributed by the translator. Through someone's lack of care, several dropped letters have been passed unnoticed. It is regrettable that before sending the book to the printers the translator did not submit his manuscript to someone with a knowledge of physical chemistry. In this way some serious errors might have been avoided. "Wolcott Gibbs" on p. 139 should be "Willard Gibbs."

A Last Diary. By W. N. P. Barbellion. With a preface by A. J. Cummings. Pp. xlviii+148. (London: Chatto and Windus, 1920.) 6*s.* net.

To speak frankly, we prefer Bruce Cummings to Barbellion—that is to say, the man as he appeared to others rather than as he chose to appear to himself. This diary, no less than the former, contains some brilliant bits of writing, but its mixture of slang and literariness, of wit and self-exposure, grows wearisome. In style and in substance Mr. Arthur Cummings's account of his brother is more pleasing. Barbellion's life was a tragedy, but he succeeded, apparently with intention, in depicting it so as to arouse irritation instead of sympathy. One longs to pity him, but that is the last thing he will permit. As a psychological document, however, the book is profoundly interesting, and for the humanist it is redeemed by the gradually touched-in portrait of simple, lovable old Nanny.

Impressions and Comments. Second series. 1914–20. By Havelock Ellis. Pp. 248. (London: Constable and Co., Ltd., 1921.) 12*s.*

It is a pleasure, and in these days a relief, to turn to diarial musings distinguished by sanity, simplicity, and sobriety of statement. Mr. Havelock Ellis may hold strong views, he may deal boldly with dangerous subjects, but he expresses himself so calmly, so frankly, and with an undercurrent of such delicate humour that it were surely impossible to take offence. Unkind fortune had not hitherto distributed the books of Mr. Ellis to this reviewer, who therefore was unprepared for the discovery that one of whose work in other directions he knew was also among the most delightful writers of our day.

Here is no room to quote, though one can scarcely refrain in the face of that exquisite "Christmas Day, 1919." Nor is this the place to challenge an occasional argument; yet in suggesting that familiarity made the ancient Greek insensitive to the charm of the Athenian atmosphere Mr. Ellis has surely forgotten the famous phrase of Euripides: ἀεὶ διὰ λαμπροτάτου βαίνοντες ἁβρῶς αἰθέρος.

That which gives a poignant and peculiar quality to the book is the clear-eyed realisation of approaching departure. We seem to see an honoured worker, resting from his labours on the deck of a vessel that bears him over calm waters to a serene sunset. He looks forward and backward with equal mind, and ever and anon pens some brief message of wisdom or good cheer for those whom he is leaving on the shore.

Diseases of the Ear. By Dr. Philip D. Kerrison. Second edition, revised and enlarged. Pp. xxi+596+vi plates. (Philadelphia and London: J. B. Lippincott Co., 1921.) 35*s.* net.

This is one of the best works on diseases of the ear that have been published for a long time. It is very full and comprehensive, and is written with lucidity and even literary charm. It cannot be too highly praised and recommended.

New Studies of a Great Inheritance: Being Lectures on the Modern Worth of Some Ancient Writers. By Prof. R. S. Conway. Pp. viii + 241. (London: John Murray, 1921.) 7*s.* 6*d.* net.

PROF. CONWAY'S "Great Inheritance" is classical—in this instance Latin—literature, and the authors with whom he is chiefly concerned are Cicero, Vergil, Horace, and Livy. It is not necessary to dwell upon the numerous instances in which Prof. Conway's originality and insight are brought to bear upon the interpretation of doubtful or obscure passages. It is enough to say that, even in dealing with comparatively technical points such as the authenticity of the minor Vergilian poems, he sees and, what is more, can convey to his readers their broader significance as elements in the history of culture, and, in particular, their bearing upon the problems of modern life. Most readers, we expect, will turn again and again to the lecture on "Man and Nature in the Augustan Poets," which, with its illuminating parallel between the circumstances which led Vergil and Wordsworth respectively to seek consolation and inspiration in Nature, is, in a brief compass, one of the best studies extant of Vergil's point of view.

In the final essay, on "Freedom and Culture," which, in a sense, sums up Prof. Conway's whole position, he indicates how the classical conception of freedom has moulded the social and political life of this country through our traditional system of education. To point out that this system of education is confined to one class which is ceasing, if it has not already ceased, to be predominant, raises the question of the comparative merits of political ideals and tendencies, which it would be out of place to discuss here.

Some Investigations in the Theory of Map Projections. By A. E. Young. (R.G.S. Technical Series, No. 1.) Pp. viii + 76. (London: Royal Geographical Society, 1920.) 6*s.* net.

THE first of the new series of technical publications issued by the Royal Geographical Society is an exhaustive investigation of map projections based upon Airy's idea of making the mean square scale error a minimum. This principle was applied by Airy to zenithal projections as affording a reasonable compromise between the stereographic projection and the projection of equal area. Mr. Young shows how the arbitrary constants in Airy's solution should really be determined, and then proceeds to compare the minimum error projection with others belonging to the zenithal class. The conclusion reached is incorporated in a recommendation to cartographers to use the equidistant projection with total area true as being the best zenithal projection for all cases, except when some specially desired feature necessitates a different projection.

Similar methods are applied to conical projections. It is shown that for a zone the minimum error conical projection is nearly identical with Murdoch's third projection—a remarkably accurate and simple process invented so far back as 1758, and in the opinion of the author the very best of all conical projections. Later chapters deal with the spheroidal shape of the earth, polyconic projections, finite errors, and the convergency of meridians.

The paper is mathematical throughout. The algebra is laborious, but the results are of great interest. Mr. Young's paper is a valuable contribution to the subject he deals with, and sets a high standard for the series it initiates.

Elementary Vector Analysis: With Application to Geometry and Physics. By Dr. C. E. Weatherburn. (Bell's Mathematical Series.) Pp. xxvii + 184. (London: G. Bell and Sons, Ltd., 1921.) 12*s.* net.

AN excellent introduction to the subject of vector analysis is provided by this book. It is admirably clear, and a natural temptation to develop so fertile a theory in excessive detail and to multiply its applications has been successfully resisted. It is a more elementary work than Dr. Silberstein's "Vectorial Mechanics," and still more so than Joly's "Manual of Quaternions." All the ideas which are based on the differential operator of Hamilton are excluded, and the applications are limited to geometry and to the dynamics and statics of rigid bodies. Enough remains to place in a clear light the general principles of the subject, and its value is less apt to be obscured by the complexity of the material. It is understood, however, that the author contemplates a second volume, in which the higher developments will doubtless be treated. Without such a sequel the reader will be left unprovided with some of the most characteristic and important notions of the calculus.

The diversity of notation has always been, and is likely to remain, a hindrance to progress. The existence of Hamilton's system seems to have had a centrifugal result, and Tait's controversial methods probably had an effect precisely the opposite of that intended. The present author adopts the notation of Gibbs. At the moment the wider diffusion of vectorial methods is very desirable, and though the absence of a uniform notation increases the difficulty of pursuing the subject in different books, it is an obstacle on which too much stress can easily be laid.

The Formation of Colloids. By Prof. The Svedberg. (Monographs on the Physics and Chemistry of Colloids.) Pp. 127. (London: J. and A. Churchill, 1921.) 7*s.* 6*d.* net.

IN this small monograph the author, whose brilliant investigations on colloids are familiar to all interested in that important branch of science, has given a very concise account of much recent work on the formation of colloids. References to the literature are given, and the book is valuable in bringing together much scattered information on the subjects of which it treats. The printing and illustrations are well done.

Atmospheric Refraction.

THE proposition that "the course of a nearly horizontal ray of light in the lower part of the atmosphere is a circular arc having a radius of 14,900 geographical miles" has been stated by Mr. Mallock in a letter in NATURE of June 9, p. 456. Mr. Mallock states later on in the same communication that rays that are pointed a few degrees up or down will still be arcs of a circle of 14,900 miles radius.

It has been customary for many years in all survey departments to assume that the angle of refraction on a ray bears to the angle subtended at the centre of the earth a ratio denoted by k, which is called the "coefficient of refraction," assumed to be constant at a given point for all rays. It is easy to see from this that the ratio of the curvature of the ray—tacitly assumed to be circular—to the curvature of the earth is $2k$; and that if $2k=1$ a horizontal ray would circle the earth. According to Mr. Mallock's result, $2k=3960/14{,}900$, taking the earth's radius as 3960 miles, which leads to $k=0{\cdot}133$. Now this is *not* a value ordinarily met with in practice. In Clarke's "Geodesy" values of k derived from observations of the Ordnance Survey are given as 0·0809 for rays over water and 0·0750 for rays over land. These values are not far different from values obtained from other surveys.

Mr. Mallock's reasoning is based on the equation

$$v_h=v_0\left(1-a\frac{H-h}{h}\right).$$

When $h=0$ this becomes $v_0(1-0{\cdot}00029)$, or v_0/μ, where μ is the refractive index of air at standard pressure and temperature. While this is correct, it appears to me to be quite erroneous to consider the equation as giving the correct velocity at heights of a few thousand feet. It may not be incorrect to state for a limited range of height that the velocity varies as the height; but surely it is incorrect to deduce the factor of this variation from an assumed law which gives the velocity at height H (the height of the homogeneous atmosphere $=8{\cdot}3$ km.) equal to the velocity *in vacuo*?

If the refracted ray is circular and of the same radius of curvature for rays deviating several degrees from the horizontal, it would follow that the value of k at two considerably different levels would be the same. Now the refraction depends on $\mu-1$, which varies as the density of the air. It is manifest that k is smaller at a considerable height than at sea-level in the proportion of the densities at the two heights. The value of k varies not only with the height, but also with the angle of elevation of the ray. The most convenient plan so far evolved is to speak of the "coefficient of *horizontal* refraction," k_0, and to give values for this quantity at various heights. Under certain average conditions for a ray from A to B, points the heights of which are h_a and h_b, the refraction may be computed by using the coefficient of horizontal refraction appropriate to height $1/3(2h_a+h_b)$, while for the reverse ray $1/3(h_a+2h_b)$ should be used. The values of k_0, which follow from purely theoretical considerations if a temperature gradient of 3° F. per 1000 ft. be assumed, vary from 0·08 at sea-level to 0·05 at 19,000 ft. for temperatures and pressures 82°, 30 in., and 25°, 15 in., respectively. These values are found to account very well for refraction in numerous Indian observations.

Refraction is not, in general, constant throughout the twenty-four hours. It is usually smallest in the afternoon at about 3 p.m., and the minimum value then reached is approximately the same from day to day. On this account observations are often restricted to the hours between 2 and 4 p.m. It may easily happen that the refraction at 8 a.m. is double that at 2 p.m. The values of k given above refer to minimum refraction. Recent research has shown that the diurnal change is due mainly to the changes of temperature in the first 300 ft. of the atmosphere; in that region the form of the ray of light is by no means circular. Beyond a height of 300 ft. temperature changes in the air due to conduction practically disappear. For rays of light which remain most or all of their length within a distance of 300 ft. from the ground, highly anomalous values of k may, and generally do, exist. In such cases afternoon refraction is smaller than is indicated by values of k already given, and in some cases is zero, or even negative. Such rays require special consideration.

Results of a good many observations will be found in my "Formulæ for Atmospheric Refraction and their Application to Terrestrial Refraction and Geodesy" (Professional Paper 14, Survey of India, Dehra Dun, 1913); and a more recent article in "The Dictionary of Applied Physics" (Macmillan and Co.), now under publication, may also be consulted.

J. DE GRAAFF HUNTER.

Dehra Dun, United Provinces, India, July 13.

THE only points in Dr. Graaff Hunter's letter to which I need refer are (1) the objection raised against taking the refractive-index gradient for the lower levels of the atmosphere as being identical with that which would make $\mu=1$ at the height of the homogeneous atmosphere, and (2) the statement that "conduction" of heat extends to a height of 300 ft. above the ground.

With regard to (1), the pressure gradient near the ground, and the density and refractive-index gradients also, decrease linearly at such a rate that if the linear relation continues to hold, the pressure and density would be zero and the refractive-index unity at the height H, and this is the gradient which should be used in correction for refraction to such heights, as the linear relation is a sufficient representation of the facts. How far depends on the order of accuracy aimed at.

Temperature effects may make a difference of 1 or 2 per cent. per 1000 ft., but in such an uncertain correction as that for terrestrial refraction this is scarcely worth notice.

The presence of water-vapour will have an effect as well as variation of temperature, and it will generally be impossible at any particular time and place to know for certain what the refraction really amounts to, especially if the course of the ray is long.

(2) It is scarcely correct to speak of the irregular distribution of temperature near the ground as being due to conduction. True conduction in the air is quite insensible compared with diffusion by eddies and the general instability of flow.

A. MALLOCK.

The X-ray Structure of Potassium Cyanide.

WRITING in the current number of the Proceedings of the Royal Society, Prof. A. O. Rankine concludes from determinations of the viscosity of cyanogen gas that the cyanogen molecule "behaves in collision like a hard body formed by two overlapping hard spheres, each of which has the kinetic properties of a nitrogen molecule." He gives as the distance between the centres of these overlapping spheres $2{\cdot}3\times10^{-8}$ cm. Prof. Rankine also remarks: "It is significant that the crystals of potassium cyanide and those of the potassium halides are usually stated to be iso-

morphous, and that, in addition, we find that KBr and KCN have nearly identical molecular volumes—43·1 and 42·8 respectively. Thus if CN replaces Br there is no appreciable change in volume, and we may conclude, tentatively, that the cyanogen radicle and the bromine atom have the same size."

Acting on the suggestion of Prof. W. L. Bragg, the writer has made X-ray examinations of small single crystals of KCN by the ordinary spectrometer method, and of powdered crystals by the modification of the method recently described by Sir W. H. Bragg before the Physical Society of London. The results of this preliminary investigation indicate that the underlying structure of KCN is similar to that of KBr, the cyanogen radicle replacing the bromine atom. For instance, the strongest reflection is that given by the [100] face at a glancing angle of 6° 15′. This corresponds to a distance of 3·27 Å. between the planes, and the calculated mass associated with the unit cube the edge of which is of this length is one-half of the mass of the KCN molecule; this is a characteristic of the face-centred lattice. The first-, second-, and third-order reflections from the [100] face have intensities which decrease in the normal way, although at a greater rate than is usually the case; the first-order reflection given by the [111] face at a glancing angle of 5° 40′ is relatively small, while the second-order reflection at 11° 30′ is normal, as is also the first-order reflection from the [110] face. These spectra correspond to those given by NaCl, where the unit of the structure consists of a cube with atoms of one kind arranged at the corners and face centres, and atoms of the other kind at the mid-points of the edges and at the cube centre.

The data obtained, while being sufficient to fix the position of the CN radicle as a whole with respect to the potassium atom, afford practically no evidence as to the disposition of the carbon and nitrogen atoms towards each other. So far as the lower orders of spectra are concerned, the CN radicle behaves as a single unit, whose power of diffracting X-rays differs from that of the potassium atom. The edge of the unit cube in the KCN crystal is 6·54 Å. Taking 4·15 Å. as the diameter of the potassium atom (Prof. W. L. Bragg, *Phil. Mag.*, August, 1920), this leaves 2·39 Å. as the width of the space, measured along the cube edge, to be filled by the CN radicle. The diameter of the bromine atom is 2·38 Å.

The results of the investigation will be published in detail elsewhere. P. A. Cooper.

Manchester University, July 28.

An Ornithological Problem.

Staying this last week-end with a friend at Overstrand, I was much puzzled on the morning of August 6 by a strange bird which I first saw sitting on some low iron gates at the end of the lawn, when I took it for some kind of hawk. It then settled for a time on a croquet-hoop, and ultimately flew away, when its long wings and tail and smooth flight again suggested a hawk. My host, who had seen it before, thought it might be a cuckoo, and this, when a little later we saw it again in flight, seemed a probable solution.

We did not see the bird again until the evening of August 7, when during a heavy shower it appeared on the lawn and perched on a croquet-hoop close to the house. I then saw that its plumage was not grey-blue, like the adult cuckoo, but a rich mottled brown, and I began to think that it might be a nightjar, though its beak seemed a little too long and its appearance in a beautifully trim garden on the edge of the sea, in the daytime, out of character. Moreover, both on gate and croquet-hoop it sat crosswise, not lengthwise as the nightjar does on a branch. It also occasionally hopped, somewhat clumsily, across the lawn and regaled itself with a worm like any thrush.

On my return to town it was suggested to me that the bird might be a young cuckoo. It so happened that I had never seen one, and so was not aware how different the plumage is from that of the adult bird. After consulting the authorities, however, such as Dresser and Lilford, I am satisfied that this is the right solution, for the mottled brown plumage is quite in order, and the beak and the length of wings and tail are clearly more those of a cuckoo than of a nightjar. Moreover, we are expressly told that the cuckoo when on the ground hops in an ungainly fashion, whereas it is doubtful whether a nightjar with its peculiarly constructed feet could hop at all. The cuckoo, like the nightjar, is normally insectivorous, but this bird might have been brought up by a thrush and imitated its foster-parent's method of dealing with worms on a lawn. Presumably the young cuckoo is not ready for its long flight across sea so soon as the adult bird, of whom we read, "In August, go he must." George A. Macmillan.

August 9.

Uniform Motion in the Æther.

It seems to be fairly generally conceded that uniform motion relative to the æther is, in principle, undetectable by optical devices. Poincaré, for instance, who did not entirely accept the positions of relativity, stated as his opinion that "optical phenomena only depend on the relative motions of the bodies concerned, and this not to quantities of the order of the square or cube of the aberration, *but rigorously*."

A very simple consideration, however, shows that such a view is untenable. Thus, if we have a vertical mirror, with a horizontal motion in its own plane relative to the earth, and if a horizontal beam strikes it, the angles of incidence and reflection must, as measured from the moving mirror, be equal, for otherwise the measured discrepancy would determine the earth's motion.

Owing to the aberration, however, these apparently equal angles are not, in general, truly equal, nor are they equal as measured from the earth. It is only when the direction of the earth's motion is in the direction of the horizontal axis of the mirror that they will be equal when so measured.

This determines the direction of the earth's motion, and from the discrepancy in the other cases the magnitude of the velocity could be found.

An effect of the FitzGerald-Lorentz contraction would be to distort angles, so that, for example, a measured right angle, the bisector of which was in the direction of the earth's motion, would be greater than a true right angle; but this would not be compensatory in the case of the mirrors, and would itself, in another connection, serve to determine the earth's motion.

In fact, angular measurements of the stars would suffer discrepancies of a maximum of about 0·001″, in opposite directions, at intervals of three months, owing to the earth's motion in its orbit, and any added motion would probably be detected if an accuracy of 0·001″ in the measurement of large angular distances could be obtained.

As another example of a different kind, the simple immersion in still or moving water of the Michelson-Morley apparatus ought, theoretically, to give a positive result, since the water moves relatively to the æther, and Fizeau's law indicates that the velocity of light in moving water is not the same in all directions; while if the water moves relatively to the apparatus, this velocity is independent of the particular contractions of the latter. E. H. Synge.

Dublin.

As Mr. Synge says, the angles of reflection and incidence as measured by an observer moving with the mirror must be equal. When the motion of the mirror relative to the earth is in its own plane, the effect of the FitzGerald contraction is the same on each angle, since it affects all distances parallel to the motion in the same ratio, while leaving those perpendicular to the motion unaltered. Thus the angles will appear equal to an observer fixed with regard to the earth. They would also appear equal if the motion was normal to the plane of the mirror, but not if it were in any other direction than these two. Even in the last case, however, the difference would depend, not on the motion of the earth, but on the motion of the mirror relative to the earth.

Again, it is true that the apparent distance between two stars must vary during the year on account of the variations in the direction of the earth's motion relative to the stars; if all larger disturbances were eliminated this could be detected, but observation of it could only determine the variations in the velocity of the earth relative to the stars, not its motion in æther or "space." The same applies to the immersion in water of the Michelson and Morley apparatus; none of these methods could tell us anything we do not already know more accurately by other means.

Harold Jeffreys.

Conical Refraction in Biaxial Crystals.

An arrangement for demonstrating conical refraction usually found in laboratories is a piece of aragonite crystal mounted inside a little tube which has one end covered with a metal foil pierced by a number of pin-holes, and an eye-lens in a focussing mount at the other end. When the tube is directed against a luminous object and the eye-lens focussed on the pin-holes through the crystal suitably oriented they are seen as luminous rings of light. Writers on physical optics who describe this experiment refer to it as illustrating *internal* conical refraction—that is, as due to the fact that the Fresnel wave-surface has a tangent-plane which touches it along a circle. I wish to point out that this is really an error. A little consideration will show that as the eye-lens is focussed on the pin-holes, which may be as small as we please, we are concerned here with the waves *diverging* from them in all directions within the crystal, and the observed effect is due to the fact that the two sheets of the wave-front intersect at a conical point. In other words, the experiment really illustrates *external* conical refraction. This is confirmed by the fact that an extended source of light may be used without interfering with the success of the experiment.

A remarkable effect is observed if, with the tube pointed towards an open window, the eye-piece is steadily drawn back from the crystal. It will be noticed that a well-defined image of each pin-hole may be traced behind the crystal for a distance of several centimetres. The formation of this continuous image by a crystalline plate with parallel faces cannot be explained on geometrical principles, and is of great interest. The effect appears to be due to the dimpled form of the wave-front within the crystal, and is being further investigated by Mr. V. S. Tamma and myself.

Coiling of Underground Shoots of Convolvulus arvensis.

The shoots ascending from the rootstock of *Convolvulus arvensis*, before they reach the surface of the ground, are frequently found to be coiled. The coils vary in diameter from one to two inches or more, and lie closely adpressed upon one another. A considerable length of shoot, in some cases three or four feet, is thus compressed into a small space. No object has been found enclosed by the coils which would serve as a stimulus; the soil contains very few stones to obstruct the straight upward growth of the shoots. In a few cases a similar coiling has been observed in the ascending shoots of *Carduus arvensis*. One of the "popular" names of *Convolvulus arvensis* is "Devil's Corkscrew." These white corkscrew coils of the shoots underground seem more likely to be the origin

Fig. 1.—Devil's Corkscrew (*Convolvulus arvensis*).

of the name than the less noticeable above-ground coiling portion.

In the accompanying illustration (Fig. 1) A–B is the rootstock; the ascending shoot, originating at B, is coiled at C, and terminates in the leafy above-ground portion at D. (The coils were slightly pulled out before taking the photograph.)

Bees and Scarlet-Runner Beans.

I should like to add to the remarks on bee visitors to the flower of the scarlet-runner bean contained in my letter in Nature of July 28, p. 684, the following further observations. Some ten days from the time of making the original notes a complete change was found in the insect visitors to the flowers and in their behaviour towards them. Instead of the smaller black and black with grey humble-bees busy over the blooms in what I termed the legitimate way, there were numbers of a larger, yellow-banded species of humble-bee that had bitten every newly developed bloom and were searching the nectaries through the perforations made in the base of the flower. They all unhesitatingly scrambled to the underneath part of the blooms, which in every instance had been bitten before the observation was made. Many honey-bees were following in their wake, busily draining the exposed nectaries of every particle of the sweet liquid that had been left or had newly formed.

The results of the two ways of visiting the flowers are very marked and distinguishable. The earlier flowers and lowest on the racemes that were first visited without injury are replaced with a good show of pods, while the later bitten blooms drop off very quickly, with only barren pedicels remaining.

The season being so unusually forward gave opportunity to the earlier insect workers, which made some return to the plant for its sweet gifts, while the later humble-bees are mere depredators that only rob and injure the plant.

Remarks on Simple Relativity and the Relative Velocity of Light.[1]

By SIR OLIVER LODGE, F.R.S.

II.

The Relative Velocity of Light.

CONSIDER once more the assumption that is either tacitly or confessedly introduced into the establishment of the Larmor-Lorentz transformation and the consequent composition of velocities.

It is this: that the velocity of light outside and far away from matter is absolute; in the sense that it will be measured as the same velocity by every observer, no matter what his relation may be to space and time—*i.e.* no matter where or when he exists, or at what unknown speed he may be moving, not even if his speed were infinite.

A very extraordinary idea that, and one difficult to believe. It is true that it follows from the equations previously written down by Larmor and Lorentz, but they were originally limited to the small range of u/c that covered all practicable observations, and so were not meant to be of universal application and pressed into infallible consequences. The merit, or demerit, of Einstein is that he had no such compunction, and was ready to follow the argument whithersoever it led; and the result—made possible by his wonderful grasp of recondite machinery which he annexed from pure mathematicians, especially recondite when gravitation was included—was a far-reaching effort towards a universal synthesis, in the course of which a few definite features amenable to observation emerged—with the known brilliant results.

Now that the velocity of light in free æther is constant is admitted by everybody, the only reasonable alternative would be some dependence on wave-length, which would mean that the æther was coarse-grained; and that is experimentally negatived by several phenomena and by all manner of determinations of what used to be called a ratio of units, "v," but is more intelligibly and satisfactorily called a measure of the product of the magnetic and electric ætherial constants μK.

But that the relative velocity of light, determined by an observer travelling with speed u to meet it, should still appear the same, and be independent of his motion, is curious, not to say paradoxical. The relative velocity of the observer and the light must be $c+u$—common-sense forbids otherwise,—but if he seeks to measure it he will get, we are told and inclined to believe, not $c+u$, but $(c+u)\div(1+cu/c^2)$, and that is simply c.

So far as I know, no one has ever measured the apparent velocity of light from a star or from one of those spiral nebulæ from which the earth is receding at hundreds, or even thousands, of miles per second. It is not easy to see how it can be done, for the readily observed Doppler effect is always attributed to relative motion of source and observer; and if those are relatively fixed it has been definitely shown that no steady motion of the medium has any observable influence on either direction or frequency (Phil. Trans., 1893, vol. clxxxiv., p. 784). Gusts, however, cause wailing; and by utilisation of the variation of an already occurring Doppler effect something may be done (*l.c.*, p. 785). But, in view of the universality of the above transformation equations, we may admit that it is unlikely that any result other than c will be obtained. It is by assuming the velocity of light constant that the recession velocity is measured; the whole observed retardation is naturally attributed to relative velocity of source and observer; though if we could be sure that all the observed relative velocity really belonged to the receiver, and none of it to the source, we should know that the reason we were able to observe an apparent change in frequency was because of the resultant speed at which we received the waves. But that is just the difficulty—we cannot tell how much of the recession belongs to the source and how much to the receiver. If we could know the observer's speed through the æther we could clearly say that he met the waves more slowly or more quickly than he would otherwise get them; and this reasonable statement has never been disproved by observation.

We ought not to claim, therefore, as some philosophers do, that the fundamental hypothesis of Einstein about observed velocity of light has been directly verified and is a sound basis on which to found a theory. The hypothesis does not justify any theory, though a successful theory may justify the hypothesis. A mistaken claim for what has been done by experiment is often made; and as clear statements are always valuable, whether right or wrong, I select for quotation one from Lord Haldane's recent book, "The Reign of Relativity," on p. 82:—

> Long before 1905 it had been found by experiment that the velocity of light appeared to be always 186,330 miles per second, whether the passage of its rays was towards us while we were at rest with regard to its source, or whether we were ourselves moving towards that source.

Now whether what is here asserted to have been "found by experiment" about the velocity of light be a fact or not, no observation of a discriminating kind had been made before 1905; and I would myself deny that any such observation has been made since. Certainly no experiment of the direct kind suggested in this quotation has ever been made—it is doubtful if it can be made. Every purely terrestrial measurement of the velocity of light has been made, and must necessarily be made, on light which has travelled round a contour, or, what is the same thing, which has gone and returned over the same path. Such an experiment proves nothing, either for

[1] Continued from p. 719.

or against a discrepancy due to the observer's motion, in the measured 186,330 miles a second. In a to-and-fro journey there is complete compensation for any possible discrepancy in speed so far as small quantities of the first order, involving the ratio u/c, are concerned. The only outstanding discrepancy to be expected is of the second order of minutiæ; and that, as many of us think, is systematically neutralised by the FitzGerald-Lorentz contraction, which, though it is a consequence of the electrical theory of matter, is stigmatised as an unreal contrivance, a mere invented refuge, by the philosophers above referred to.

Relativity has only to do with second-order effects; it essentially depends on ds^2, the square of a small interval; but the statement above quoted is not entirely about second-order effects; it relates to the first order—to a journey in one direction—and would require for direct verification an observation of the difference in the time of a single journey, when the observer is moving (*a*) with, (*b*) against, an æther stream.

The nearest approach to a measurement of this kind that might conceivably be made would be a vastly improved determination of the velocity of light by a method based on the observation of some periodic feature in Jupiter's satellites during the course of Jupiter's year. To make a determination possible at all, the earth must be moving either to or from Jupiter at the time—it does not matter which—and the chance of obtaining a positive result depends on the varying angle which the line joining earth and Jupiter makes with the sun's way, or rather with the direction of locomotion of the solar system through the æther, whatever that direction may be.

But I think it is generally agreed—subject, however, to the opinion of the chief authority on those motions, Prof. R. A. Sampson—that the gravitational theory of the satellites, perturbed as they are by each other as well as by the oblateness of Jupiter, is not yet nearly perfect enough to enable us to decide the question whether the velocity of light deduced from their eclipses is dependent on the season of Jupiter's year,—in other words, whether light appears to reach us with the same speed when we are looking at Jupiter down-stream as it does when we are looking at him up-stream (see Phil. Trans., 1893, vol. clxxxiv., pp. 746, 779, and 785). For we have no means of determining the instant at which the light starts from Jupiter; all that we can really observe is the time that light takes to transit the distance travelled by the earth in the interval between two eclipses.

Apart from all astronomical observation, however, it has been claimed that the rather recent pair of experiments of Prof. Majorana, with moving mirrors (*Phil. Mag.*, February, 1918, p. 163, and January, 1919, p. 145), do establish the thesis that the observed velocity of light is independent of the relative motion of observer; but they, too, are observations made on a to-and-fro journey, and, therefore, for the present purpose, are beside the mark. If light were a projectile, it could be hit forward by a moving mirror, like a cricket ball, but no one can suppose that any kind of impact can alter the subsequent velocity of waves through a medium, nor is it to be supposed that motion of a source can affect the travelling rate of waves which it has emitted and abandoned.

More Careful Discussion of Doppler Effect.

Motion of the source does not affect velocity, but if a moving source emits waves at constant frequency n, the wave-length ought to be different in different directions θ, and this modified wave-length,

$$\lambda' = \frac{c \cos \epsilon + u \cos \theta}{n},$$

can be observed by a fixed observer, and, when compared with the normal $\lambda = c/n$, is called the Doppler effect. The small aberration angle ϵ, between ray and normal to wave-front, is defined by $c \sin \epsilon - u \sin \theta = 0$.

If, however, the source is fixed in the æther, and only an observer is moving, the velocity and the wave-length are both quite normal; but the frequency with which the waves are encountered by the observer will depend on the speed and direction of his own motion. Consequently there is again an observable Doppler effect expressed as

$$n' = \frac{c \cos \epsilon + u \cos \theta}{\lambda},$$

to be compared with $n = c/\lambda$.

Hence if an observer steadily chases a source, keeping a fixed distance between them, the two effects—the real wave-elongation and the apparent frequency increase—neutralise each other *exactly* whatever the direction of joint motion, because $n\lambda' = n'\lambda$. So drift through a medium produces no trace of a Doppler effect.

Nevertheless, the two types of effect—one with source only moving, the other with receiver only moving—are not identical; they are the same when both are moving in the same direction, so as to be relatively at rest, but not the same when they are moving relatively to each other. For, writing u/c as α, and taking the case of relative recession between source and receiver, we get, for the observed frequency ratio,—
if it be the source only which is moving,

$$\frac{n'}{n} = \frac{\lambda}{\lambda'} = \frac{1}{\cos \epsilon + \alpha \cos \theta};$$

while if it be the receiver only which is moving,

$$\frac{n''}{n} = \cos \epsilon - \alpha \cos \theta.$$

Hence

n'' is not equal to n', but

$$\begin{aligned} \frac{n''}{n'} &= \cos^2 \epsilon - \alpha^2 \cos^2 \theta \\ &= 1 - \alpha^2 \sin^2 \theta - \alpha^2 \cos^2 \theta \\ &= 1 - \alpha^2, \end{aligned}$$

which is the square of the usual FitzGerald con-

traction. The relativity doctrine, in order to avoid recognising any such difference, would presumably distribute this factor between the two expressions, making them

$$\frac{\lambda'}{\lambda}=\frac{\cos\epsilon+a\cos\theta}{\sqrt{(1-a^2)}},$$

$$\frac{n''}{n}=\frac{\cos\epsilon-a\cos\theta}{\sqrt{(1-a^2)}};$$

so that there shall be equality between $n''\lambda'$ and $n\lambda$, and then it is impossible to tell to which body the motion belongs.

Note that the introduced β factor cannot in this case be attributed to a FitzGerald contraction of the grating—if a grating is used as the measuring instrument,—for the aspect of the grating to the incident light, and therefore to the motion under examination, is normal, not tangential. But the law of reflection is interfered with by the motion, in a way investigated in Phil. Trans. for 1893 (vol. clxxxiv., A, pp. 793–800), and the result is to give a modified deviation which will be interpreted as part of the Doppler effect. The discrepancy is reckoned, on p. 798 *loc. cit.*, for any incidence angle i and any drift angle ϕ, as $\alpha^2\cos^2 i\sin 2(i-\phi)$; so it is a maximum for normal incidence and for a drift direction making 45° with the ray.

This might readily have the average value $\frac{1}{2}\alpha^2$ needed to replace the ordinary β factor, but in so far as it yields a factor depending on the angle ϕ its changes *seem* amenable to observation.

In the same Phil. Trans. paper I show (p. 787) that the Doppler effect observed by a moving grating is really an aberration effect, due to the motion being partly across the diffracted rays, although the incident ray may be along the drift. For a grating *must* deviate in accordance with wave-length, whether it be moving or stationary, so far as first order is concerned.

But the question arises, What happens when the grating is drifting partly in its own plane ($\phi=90°$) and thereby suffering a FitzGerald contraction?

The answer seems to be that the extra aberration due to this drift will just compensate the second-order Doppler effect otherwise to be expected from the ostensibly narrower-ruled grating. There are certain possibilities here, however, which need looking into.

Summary of this Portion.

The Einstein formulation seems to justify itself by results, and may be supposed to strengthen the claims of any philosophy suggested by it, as well as to establish the explicit assumptions on which the theory is based; but we should be careful to perceive that justification is of this subsequent inferential order, and that it is not primarily the outcome of experiment—certainly not of any old unexplained measurements. The whole thing depends on the law that we postulate for the composition of velocities. When two velocities in the same direction are compounded, is the resultant velocity $u+v$, or is it really $\dfrac{u+v}{1+\frac{uv}{c^2}}$? Einstein's assumption led to the latter as a physical truth, and if that is right it is algebraically undeniable that if one of the component velocities is c, the resultant will be c also; and any such criterion as my old experiment (1892–97) with rotating discs, whereby it was sought to observe a possible difference between $c+v$ and $c-v$, cannot give any positive result. Nor can it, by giving the result zero, prove that v is 0, because, as a matter of simple algebra, if $u=c$, no sort of v can make any difference, not even if it be infinite.

So also Michelson's experiment can show nothing, nor can any velocity compounded with the velocity of light exhibit itself in any way, if that is the true law of composition of velocities in general.

But why into this composition formula should there enter the velocity of light? If, for instance, the composition is between a ship and a tide, or a satellite and a planet, or the usual railway train and embankment, one cannot avoid the question, What on earth has the speed of light to do with it? any more than the speed of sound or of a messenger boy, or whatever agent it is which brings information to an observer. It is true that the law of composition is essential to the principle of relativity, but when we are engaged in establishing that principle it is scarcely fair to assume it.

The curious law of composition is deduced from the Lorentz transformation of space and time to other co-ordinates,

$$x'=\beta(x-ut)\;;\; t'=\beta\left(t-\frac{ux}{c^2}\right)\;;\; \beta^2(c^2-u^2)=c^2\;;$$

and in the establishment of these equations it is assumed that all observers have the same value of c, or that $x^2-c^2t^2$ is invariant.

I apprehend that for this transformation, treated as formal correspondence, there is a good deal to be said, so that any law deduced from it may be true with all its consequences; but it is surely a mistake to say that the measured velocity of light has been experimentally proved constant. So far as the velocity of light is concerned, the reasoning is circular. I suggest that it is also dangerous to adopt a mode of exposition which denies reality to the FitzGerald contraction. Still more is it premature to assume, as more than a temporary conclusion, that no phenomenon demonstrating our motion through the æther of space can ever be discovered; which carries with it the implied suggestion that the inability is because such a medium does not exist; so that not only can all motion be treated undynamically as a purely geometrical or kinematic relation, but so also that in absolute truth there is no difference discernible between a dog wagging its tail and the tail wagging the dog. Kinematically, it is as easy to take the apple as standard of reference as it is to take the earth, but physically and ener-

getically the treatment can only be satisfactory when their combined or reciprocal motion is balanced about their common centre of gravity.

Centres of gravity, however, presumably disappear from relativity; and, what is more serious, so does the conservation of energy. For if there is nothing absolute about speed there can be nothing absolute about kinetic energy. The relativity expression for kinetic energy contains an arbitrary constant; and whether energy is conserved or not becomes a matter of convenience and definition. The claim that relativity pressed to extremes does away with all conservation, as hitherto understood in physics, has been seriously made by the eminent mathematician, Prof. Hilbert, of Göttingen. On the other hand, it might be replied, according to Sir Joseph Larmor, that kinetic energy has always been treated as relative to some other body on which work might conceivably be done, and that the really invariant quantity is not energy, but the integral of energy with time, called "action"; or as it may be regarded, perhaps preferably for some purposes, i times angular momentum.[2] For this appears to be independent of frames of reference—which energy certainly is not.

Acceptance of the theory of relativity correlates results, but does not explain them. The theory does not even seek to explain or account for phenomena: they just are so. It is not a dynamical theory, it is a method of arriving at results, like the second law of thermodynamics and the conservation of energy. The full dynamical explanation remains to be worked out, and it may turn out to be on very much the old lines along which we had previously regarded physical phenomena. The true relation between æther and matter, and how their interaction generates and affects light, is an immense subject, not in the least exhausted, and barely encroached upon, by the perception that certain consequences inevitably follow from an admission that the velocity of light is a critical limiting velocity, which cannot be exceeded, and which when compounded with any other velocity retains its old value.

Whether the properties of the æther can ever be formulated in terms of the same sort of dynamics as we have found so fruitful and effective in dealing with matter is at present an open question. Quite possibly a different dynamics may be needed, one perhaps of which we have as yet no conception; but let us not shut the door on discovery, assume that nothing of the sort can ever be arrived at, and think that pure mathematical abstractions, glorified and complicated sufficiently, can be an ultimate embodiment of physical laws or can adequately express the facts of Nature.

(To be continued.)

[2] Which, by the way, is very suggestive of a constitutional gyrostatic æther structure.

The Conference of the International Union against Tuberculosis.

THOSE who have followed the course of tuberculosis in this country have noted that during the years of the war there was a sudden interruption in the fall of the curves illustrating case-rate and death-rate from that disease. Our work was then in fields abroad. Now, however, that we are getting back to pre-war conditions, peoples and nations are again joining forces in a new campaign against tuberculosis in our civil populations, and at the recent conference in London of the International Union against Tuberculosis delegates from forty nations, including China, Japan, Persia, and Czecho-Slovakia, met to discuss the great question of the cure and prevention of tuberculosis. Science knows no national borders, and it is obvious that the union is anxious to work with men from all nations, and to this end has drawn up a series of tentative regulations in order that when German physicians have composed the differences amongst themselves arrangements may be made for their reception into the councils of the union. The secretary of the old International Association against Tuberculosis appears to have assumed that everything would go on as before, and somewhat injudiciously made an attempt to call the old association together as a rival to the conference of the union of Allies and neutrals held in Paris last year. The wiser amongst his countrymen were against this, and at present the German physicians are divided into two camps. For the present the International Union is content to make good its own footing, go its own way, and lay down its own lines of operations, at the same time leaving the regulations so elastic that as asperities are smoothed down and difficulties removed German workers may come in and take their part in its great work; and it is hoped that steps towards this will have been taken when the meeting is held in Brussels next year, or, at any rate, in Washington two years later. By that time the League of Nations may have got under way, and the international character of the union may have become complete.

At the opening sitting of the London meeting the Foreign Secretary, Lord Curzon, and the Minister of Health, Sir Alfred Mond, blessed in no uncertain terms the ideals and work of the union, and their presence no less than their works may be accepted as of good omen that the Government authorities will, in their anti-waste difficulties, remember that a penny wise Health Ministry may be pound foolish where the public health is concerned, and that the same holds good as regards the Board of Education.

Prof. Calmette, in a most interesting opening address characterised by all the clearness of vision and beauty of expression for which this French savant is noted, outlined a new hypothesis

as to the importance of tuberculosis "carriers"—*i.e.* centres of infection, themselves healthy to all intents and purposes. He claims (though the claim is not universally admitted) that von Pirquet's method of diagnosis is sufficiently characteristic to allow of a decision as to whether a patient is the subject of bacillary infection, or, in other words, capable of reacting to tuberculin as a result of the presence in the patient of a sensitising substance derived from the tubercle bacillus. Prof. Calmette holds, moreover, that by means of this reaction it is possible to work on a grand scale and to determine whether peoples and tribes, infants and adults, are infected by, or free from, tuberculosis. He quotes Col. Cummins and others to the effect that among African tribes about the equator where civilisation has not yet penetrated, and among the nomadic tribes of Arabs and Berbers, tuberculous infection is non-existent, or very rare, whilst in Natal, among the Zulus in the Transvaal, and in Madagascar, as also in the larger cities of North Africa, it is very prevalent. Those living in huts and native villages are, however, gradually becoming infected by contact with men from without. In the hinterland of the Cameroons from 3 to 6 per cent. only of adults are yet affected, whilst many aboriginal tribes are still quite free.

In civilised countries, although the reported percentage of tuberculous infection is comparatively high, a careful examination by the von Pirquet test and an examination of patients who die from other diseases would, Prof. Calmette claims, indicate the infection by the tubercle bacillus of many who, as yet, show no signs of tuberculous disease, and he believes that in the overcrowded cities of Europe and the United States few escape tuberculous infection, although the chances of death from tuberculosis are little more than one in eight. In the country districts the figures are not so high. Amongst the Kalmucks, even where the inhabitants have little intercourse with towns, 69·4 per cent. of the men and 30·6 per cent. of the women give a positive tuberculin reaction, whilst on the outskirts of the same territory, where commercial relations with the Russian population are very close, 95·7 per cent. of male adults and 88·5 per cent. of women give a positive reaction. Moreover, where differences occur, these are due very largely to the fact that tuberculous infection has been implanted in certain races over a longer or shorter period of time, although infections are also variable, being rare and slight or frequent and massive according to the particular mode of life of the people. Those who have been longest protected by virtue of their isolation from contact with the tuberculous prove to be most susceptible, aboriginal tribes and infants being the virgin soil on which the tubercle bacillus flourishes most luxuriantly. In the races that have been contaminated for centuries and exposed from infancy the disease assumes a chronic, slowly progressing form; but almost all become infected. He finds evidence in support of his contention in the susceptibility of the bovine species to tuberculosis in the domesticated condition, although the wild cattle of Madagascar and of the pampas of the Argentine are said to be free from this disease. (It was found by the Royal Commission on Tuberculosis that Jersey cattle, though free from tuberculosis in the island, were readily infected when brought over to this country.)

Prof. Calmette is of opinion that the spread of human tuberculous infection throughout the world is due entirely to disseminators of virulent bacilli, most frequently through persons suffering from phthisis, who scatter enormous numbers of bacilli in their sputum and intestinal excretions either directly or by means of objects soiled by them, or again through the agency of living carriers, such as flies. These open tuberculous cases are not the only factors in the dissemination of the disease. Many apparently healthy individuals suffering from latent or concealed tuberculous lesions which can be detected only by the tuberculin reaction are a source of danger in that they eliminate bacilli intermittently in their glandular or intestinal excretions, thus spreading infection in their environment.

E. C. Schroeder and W. E. Cotton found that 46 per cent. of cows giving a positive tuberculin reaction and showing no clinically demonstrable lesion discharged bacilli intermittently in their excreta, and that swine fed on these excreta easily became infected.

Similar observations were made by the Royal Commission on Tuberculosis, which, injecting tubercle bacilli into the circulating blood of healthy cattle, demonstrated their early appearance in the milk, whilst Calmette and Guérin showed that some of the bacilli injected into the blood-stream are eliminated through the bile passages. Lydia Rabinowitsch and Kempner, Tirze, with others in Germany, and Sheridan Delépine in England, have made similar observations with regard to the mammary glands of cattle. More recently it has been claimed by several observers that bacilli may often be found in the milk of tuberculous human mothers, even when the disease is in its early stages, or where only lymphatic glandular lesions are present. Prof. Calmette suggests that in the children of these mothers serious forms of tuberculosis are set up by slight but oft-repeated infections through breast-feeding or through prolonged or numerous accidental contacts with intermittent disseminators of bacilli. He goes further, and holds that when tuberculosis appears in environments where it has hitherto been absent it may have been introduced by a bacillus-carrier unrecognised because apparently healthy, which nevertheless has spread virulent germs either in excretions or through glandular secretions—*e.g.* milk in the case of lactating women; also that the disease in these more recently contaminated countries is more serious and more rapidly progressive than in the countries longer infected, and that it then assumes the form met with in young children rather than that met

with in adults. He argues from all this that individuals with occult tuberculosis—the so-called healthy carriers of tubercle bacilli—are largely responsible for the spread of tuberculosis, not only amongst aboriginal and hitherto isolated peoples, but also amongst infants. He claims that this recently acquired knowledge of an unexpected danger makes the organisation of social defence against tuberculosis more difficult than when prophylaxis had to be based only on the education and isolation of phthisical patients, though he concedes that these are the principal disseminators of the disease. New peoples and infants should, wherever possible, be protected through a system of detection based both upon the judicious use of tuberculin tests and upon clinical examinations of the glandular system mainly by means of radioscopy.

It was interesting to find that Dr. Eric Pritchard, working along these lines during a period of ten years, had passed through his hands some thirty children who, by a process of injection with Koch's original tuberculin extending over five months, first in minute doses, to which they reacted, gradually increased up to 1 mg., to which the reaction was no more marked, could be immunised against any infection they were likely to be exposed to in the course of their lives. No accident such as might have been anticipated had occurred, and he was very hopeful that they had passed over that susceptible period of which Prof. Calmette had spoken.

It was felt by some who heard Prof. Calmette that his hypothesis, unless more fully explained, might lead to great misconception on the part of the public and be advanced as a reasonable excuse for inaction. If any apparently healthy person may be a "carrier"—and all may be infected in infancy—what good are elaborate precautions against tuberculous infection? The various public authorities might feel justified (and some might wish this) to sit with folded arms and tightly buttoned pockets. Later Prof. Calmette made it clear that his reference was only to those who had not hitherto been brought into contact with tuberculous patients, such as native races and infants, and that in civilised tuberculous communities other factors, surroundings, conditions of life, sources of infection, etc., must all receive due consideration. It was insisted that much information on these points had already been accumulated, and that the time had undoubtedly arrived when the aid of legislation should be called in for the prevention of tuberculosis. Two great sources of infection, human and bovine—expectorations from the former, and milk from the latter—containing massive doses of tubercle bacilli, must still be dealt with, and dealt with effectively. No measure conducing to the removal of mass infection should be neglected. Panic or phthisiophobia may well be discouraged when we learn from Sir George Newman that in seventy-three years, since 1847, when the death-rate from tuberculosis was 3189 persons per million living, there has been a fall of 74 per cent., the standard death-rate from phthisis in this country in 1920 being 842 per million living. In other countries the decline, though not so marked, is still very substantial.

One feature was very prominent throughout the whole of the discussions. Although the search for prophylactic aids should not be discontinued, it must be recognised that the processes involved in tuberculosis are of a type different from those involved in most of the acute infective diseases, such as typhoid, plague, and the like, and, accepting this, we must follow Sir George Newman in his advice that "there is no beaten track in the further conquest of tuberculosis"; "the healthy child and the adult must be protected from massive, frequent, and prolonged infection"; "the powers of resistance of the patient must be fortified." "Freedom of thought, wide and deep research, and mobility of action will be necessary. Of much are we still in doubt, but of three things we may be certain. Only by surveying the complex problem, as a whole, in the spirit of preventive medicine, and co-ordinating the respective factors concerned, only by thorough, constructive, and intensive practice of our principles and by searching and finding the hidden secrets of immunisation, shall we at last conquer this disease."

The Progress of British Forestry.

The First Annual Report of the Forestry Commissioners (H.M. Stationery Office, 1921, 9*d*. net) deals with the period ended September 30, 1920, since which date a whole planting season has intervened; but a preliminary note gives information of the progress made to date. The Forestry Commissioners are now in actual possession of 103,100 acres of land, of which 68,100 acres are classed as plantable with timber trees. The planting operations of the season 1920–21 have been successful, and the total area of new plantations is now about 8000 acres, while the stock of young trees in the nurseries is sufficient to plant next season a largely increased area.

The Report opens with a sketch of the history of forestry in the United Kingdom, showing the stages which led to the passing of the Forestry Act in 1919. State forestry is a new departure in this country, and this part of the Report will instruct the public in the significance of a national forest policy. In the first period—that of destruction of the original forests, which lasted in some districts up to 1750—great clearances were made for agriculture, sheep pasture, and the smelting of iron-ore. In the next period—that of private

enterprise, 1750–1885—landowners attempted by their own efforts to re-establish the depleted woodlands, and they were aided only by voluntary associations like the Society of Arts and the Dublin Society, which encouraged effectively the planting of trees by their prizes and premiums. During the war, when it was a choice between importing food or timber, it was the timber available in privately owned plantations that enabled the people to be fed.

In the third period—that of inquiry, 1885–1915—it was gradually borne in upon the public mind that unaided private enterprise could no longer cope with the growing demand for timber by our ever-increasing industries and that the primeval forests of the world were not inexhaustible. Imported timber increased continuously in price during these thirty years. Select Committees, Departmental Committees, and Royal Commissions on Forestry followed in quick succession and made recommendations which were mostly unheeded. The Development Commissioners appointed in 1909 failed "to purchase and plant land found after inquiry to be suitable"—one of the duties imposed upon them—but it must be admitted that they did useful pioneer work in providing increased educational facilities, in appointing advisory forest officers, and in encouraging with loans certain municipalities to afforest their water-catchment areas. The state of affairs, practically much inquiry and no afforestation, was unsatisfactory in time of peace. One year of war showed how critical the position was in a time of national emergency.

The final stage in our forest history—that of State action, which began in 1915 with the setting up of Lord Selborne's Committee to expedite home fellings of timber—is characterised by the adoption of a definite national forest policy by the Government, which was approved by Parliament when the Forestry Act was passed in 1919. This policy has two aims. Its ultimate objective is the creation in the British Isles of reserves of standing timber sufficient to tide the nation over three years in time of war. For this purpose the State must afforest 1,770,000 acres of new land—1,180,000 acres in forty years, and the whole in eighty years—and at the same time secure the continuance under timber (with an increased production) of the 3,000,000 acres of private forests which existed in 1914. The immediate objective is a ten-year scheme, based on a block grant of 3,500,000*l.* In this decade the Forestry Commission will afforest 150,000 acres of new land owned or leased by the State. The Commission is also bound to aid private owners and local authorities in planting 110,000 acres during the ten years.

The Report shows that there is no difficulty in the State acquiring and planting the acreage mentioned in the preceding programme. It is another story with regard to private forestry, for aid to which the Commissioners set aside 327,000*l.*, of which 137,000*l.* has been allotted to proceeds-sharing schemes between private individuals or corporate bodies and the State, and 190,000*l.* to grants and loans. However, the proceeds-sharing schemes, being hedged round with cumbersome rules to safeguard the public purse for the period of a rotation (fifty to one hundred years), are unpopular with landowners. Similarly, the statutory regulations, under which 2*l.* grants per acre are made for planting, prove to be so onerous as to offer no inducements to private individuals. The Commission must obtain powers to amend these regulations, which defeat the object of assisting landowners to make plantations.

The Report gives a detailed account of the operations carried out during the year, illustrated with a map showing the land acquired and the present planting centres. Education, research and experiments, and publications are dealt with briefly. Tables of imports of timber, statutory orders and rules, and other official documents conclude a Report which deserves to be studied by all interested in the progress of forestry in this country.

Notes.

THE classical experimental plots which Lawes and Gilbert started at Rothamsted have been of the greatest service to agricultural science, and their importance is constantly increasing. Fundamental questions in the physics, chemistry, and biology of agriculture can be attacked with more confidence in the light of results obtained from long-continued field experiments carried out on a systematic plan. Further, the results are capable of statistical examination. The importance of the Rothamsted experiments led to the institution of a parallel series at Woburn in 1876 by the Royal Agricultural Society. The Woburn soil is light and sandy, but that at Rothamsted is a heavy loam. The two series of experiments enable instructive comparisons to be made between these two soil types. All interested in agricultural science received with concern the decision of the council of the Royal Agricultural Society to relinquish—owing to economic conditions—the Woburn experiments. Fortunately the danger has been averted. Arrangements have been made for the experiments to be continued under the auspices of, but legally distinct from, the Rothamsted Experimental Station. The general portion of the Woburn farm will continue under the direct control of Dr. A. J. Voelcker, who for many years has carried out the duties on behalf of the Royal Agricultural Society. The new arrangement will not only ensure the continuance of the valuable work already done, but will also lead to a closer contact with the work of Rothamsted.

AT our request, Prof. C. Runge, of Göttingen, has been good enough to send us the following list of leading men of science in Germany who have died

since the beginning of the late war. The list is not, however, complete, and may be supplemented later. Short obituary notices of some of the men will be found in the *Geschäftliche Mitteilungen der Göttinger Gesellschaft der Wissenschaften,* 1918–19–20 (Weidmannsche Buchhandlung, Berlin S.W.68, Zimmerstr. 94) :—W. Lexis, mathematician and statistician, August, 1914; W. Hittorf, physicist, November, 1914; A. von Auwers, astronomer, January, 1915; A. von Könen, geologist, May, 1915; E. Riecke, physicist, June, 1915; P. Ehrlich, physician, August, 1915; H. Solms-Laubach, botanist, November, 1915; R. Dedekind, mathematician, February, 1916; E. Mach, philosopher and physicist, February, 1916; K. Schwarzschild, astronomer, May, 1916; R. Helmert, mathematician and physicist, June, 1917; A. von Baeyer, chemist, August, 1917; G. Frobenius, mathematician, August, 1917; A. von Froriep, anatomist, October, 1917; H. Vöchting, botanist, November, 1917; C. Rabl, anatomist, December, 1917; G. Cantor, mathematician, January, 1918; L. Edinger, physician, January, 1918; E. Hering, physiologist, January, 1918; F. Merkel, anatomist, May, 1919; S. Schwendener, botanist, June, 1919; E. Fischer, chemist, July, 1919; H. Bruns, astronomer, 1919; Th. Reye, mathematician, July, 1919; W. Voigt, physicist, December, 1919; P. Stäckel, mathematician, December, 1919; W. Pfeffer, botanist, January, 1920; O. Bütschli, zoologist, February, 1920; and W. Förster, astronomer, 1920. J. Elster, physicist, and Joh. Thomae, mathematician, have died recently. In addition to the above, several other German men of science were referred to in the obituary notice of Prof. von Waldeyer in NATURE of May 19, and news has also reached us of the following deaths not previously recorded in these columns :—Prof. G. A. Schwalbe, Strassburg, on April 23, 1916, age seventy-one years; and Prof. Karl von Bardeleben, editor of the *Anatomischer Anzeiger,* on December 19, 1918, age sixty-nine years.

THE tendency towards a more popular form of official publications has been evident in recent annual reports of H.M. Chief Inspector of Factories. The report for 1920 is divided into twelve chapters dealing with such matters as safety, dangerous trades, welfare, lighting, etc., prefaced by an introductory general section. The work of the Departmental Committee on Lighting in Factories and Workshops has now been resumed, and the Committee is assisting in the preparation of a pamphlet summarising the chief essentials of industrial illumination. We observe that the scope of the Committee has been somewhat restricted by the prevalent demand for economy. We could wish that the demand was applied with less severity to research of this description, in a field where much remains to be learned and results of experiment may have great economic value. It is, however, gratifying to observe that the recognition of the value of good lighting is increasing. One of the strangest facts mentioned in this report is the habitual disregard, by some firms, of natural illumination. Window-space is not infrequently cramped; existing panes are found to be broken and covered with sacking, or obscured by paint, oil, or dirt. Seeing that daylight costs nothing, and, according to recent experiments in silk factories, leads to 10 per cent. better production than average artificial lighting, this is evidently a direction in which a demand for economy might be justly pressed and expenditure on publicity well repaid. Another point commented upon in the report is the need for protection of the eyes against the "flash" of arc-welding. Apparently exposure of a few seconds may have ill effects, though fortunately cases of permanent injury seem to be rare. The cataract prevalent among glass workers is now believed to be due, not to ultra-violet rays, but to the continual exposure to intense heat. Suitable Crookes glasses would afford protection, but it is difficult to induce workers to make use of them. Here, as elsewhere, educational work, such as that conducted by the British Industrial "Safety First" Association, is clearly needed.

WE regret to see the announcement of the death, at seventy-nine years of age, of Prof. G. T. Ladd, Clark professor of metaphysics and moral philosophy in Yale University, founder of the American Psychological Association, and author of many important works on philosophy and psychology.

DR. JAMES MARCHANT, director of the National Council for the Promotion of Race-Regeneration, has been appointed a Knight Commander of the Order of the British Empire.

THE council of the Society of Chemical Industry has decided to institute a Messel memorial lecture in memory of Dr. Rudolph Messel. A gold medal with an honorarium will be presented to the lecturer, and for the present the remainder of the income from the bequest to the society will be allowed to accumulate.

WE learn from the *British Medical Journal* of August 6 that the French Academy of Medicine has elected the following foreign correspondants :—Sir Robert Philip (Edinburgh), Sir Humphry Rolleston and Sir D'Arcy Power (London), Dr. Brachet (Brussels), Prof. Christiansen (Copenhagen), Prof. L. J. Henderson (Harvard University), Dr. Lucatello (Padua), Dr. Dominguez de Oliveira (Oporto), Dr. de Quervain (Berne), and Dr. Soubbotitch (Belgrade).

DR. J. CHARCOT, the French polar explorer, sailing in the North Atlantic in his exploring vessel, the *Pourquoi Pas,* has succeeded in landing upon the islet of Rockall, which lies some 260 miles west of the Hebrides and 185 miles from St. Kilda. Rockall is a pinnacle about 75 ft. high rising from a shallow bank which has more than once proved disastrous to shipping. It has seldom been visited, and the *Times* records only five authentic instances of landing previous to Dr. Charcot. The interest of Dr. Charcot's feat lies in the geological specimens which he is reported to have obtained from the rock.

IT is announced by the *Times* that Mr. Edwin Naulty, an American aviator, intends to attempt an aeroplane flight across the North Pole next month. He proposes to start from Point Barrow, in Alaska,

and hopes to reach the north-western corner of Spitsbergen. The aeroplane will carry four men and fuel for a fifty hours' flight. If conditions permit, several landings will be made on the polar ice, but if this proves impossible the 1800-mile flight will be made without descent. From Spitsbergen Mr. Naulty proposes to continue his flight *via* Norway to London. Provided clear weather is experienced, it will be possible to make valuable observations on the distribution of ice and air-currents. The flight may throw some light on the doubtful existence of land in the eastern part of the Beaufort Sea.

A TRADING expedition to Siberia *via* the Kara Sea is on the point of leaving Europe. Two cargo-boats from Liverpool, two from Hamburg, and one from Göteborg are to meet at the Russian port of Murmansk, where they will be joined by the ice-breaker *Alexandria* from Leith. The expedition is carrying about 11,000 tons of cargo, most of which is destined to enter Siberia *via* the Yenisei River. This route to Siberia has been used from a very early date, but for a long time fell into disrepute owing to the difficulties presented by ice in the Kara Sea. These difficulties, however, have been exaggerated, and for some years past one or more vessels have made the passage every summer in August or September. The expedition is being organised by the All-Russian Co-operative Society, Ltd., London.

A PROGRAMME has been issued of the autumn meeting of the Institute of Metals to be held at Birmingham under the presidency of Eng. Vice-Admiral Sir George Goodwin on September 21–23. There will be a general meeting on the morning of September 21 in the hall of the Municipal Technical School, at which the Lord Mayor of Birmingham will deliver an address of welcome. The remainder of the morning and the whole of the morning session of September 22 will be devoted to papers dealing with the constitution and properties of various metals and alloys, and, so far as time permits, each paper will be followed by a brief discussion. In addition to the formal meetings, there will be excursions to various works in or near Birmingham, and on the afternoon of Wednesday, September 21, a visit will be paid to the University of Birmingham. The guests will be received by the Vice-Chancellor, Sir Gilbert Barling, Bart., and an address delivered by the Principal, Mr. C. Grant Robertson. Full details of hotel accommodation, railway arrangements, etc., are given in the programme, which can be obtained from the Secretary, the Institute of Metals, 36 Victoria Street, S.W.1.

AFTER seven years' cessation (the result of the war) the excavations at the Meare Lake Village, near Glastonbury (Shapwick and Meare are the nearest railway stations), will be resumed by the Somersetshire Archæological and Natural History Society on August 29, and continued for three weeks (exclusive of the filling-in). The work will be under the direction of Dr. Arthur Bulleid and Mr. H. St. George Gray, who have worked in double-harness at the lake villages for a number of years. The antiquities discovered in past years at Meare are exhibited in the Somerset County Museum at the society's headquarters, Taunton Castle, while those from the Glastonbury Lake Village (described in two royal quarto volumes) are to be seen, for the most part, in the museum at Glastonbury. There is a good deal of expense attaching to this work besides the labour of about eight men; the money in hand is quite insufficient for the work contemplated, and donations will gladly be received by Mr. St. George Gray at the Somerset County Museum, Taunton.

JULY was exceptionally warm and dry in many parts of England. The Greenwich Observatory records, using the civil-day values published in the Registrar-General's weekly returns, give 68·5° F. as the mean temperature for the month; the mean maximum was 81·5° and the mean minimum 55·5°. In the last eighty years, since 1841, July has been warmer only in two years, 1859 with the mean 69·5° and 1868 with the mean 68·9°, and in both 1852 and 1911 the mean temperature exceeded 68°. In July this year there were four days with the shade temperature 90° or above; the highest temperature was 94° on July 11. In 1868 there were six days in July with the shade temperature 90° or above, and July, 1881 and 1900, each had four days with 90° or above. The highest temperature on record in July at Greenwich is 97·1° in 1881. There were four days in July this year with the temperature in the sun's rays 150° or above. The total rainfall at Greenwich for the month which has just closed was 0·15 in., which is the smallest July measurement for nearly a hundred years; the only July with a smaller total was in 1825, when the amount was 0·10 in. The only other years with the July rainfall less than ½ in. are 1835, 1864, 1878, 1906, and 1911. The rainfall has been less than the normal in each of the last twelve months from August, 1920, to July, 1921, with the exception of September, 1920. In the twelve months the total rainfall at Greenwich is 14·98 in., which is 9·43 in. less than the average for the last hundred years, and only 61 per cent. of the normal. The *Times* for August 5 gives a communication from its weather correspondent, "Driest Twelve Months." It mentions that in the east and south-east of England many places besides London had less than 0·25 in. of rain in July, whilst the measurements in some of the western districts were well above the normal. The smallest rainfall for the twelve months is 11 in. at Howden, Yorkshire, and this is stated as quite without precedent in the United Kingdom, so far as can be seen at present. At Yarmouth the rainfall for the twelve months was 12·8 in.; at Benson, Oxon, 13·1 in.; Cranwell, Lincs, 13·7 in.; Kew, 15·0 in.; and Croydon, 15·3 in. The lowest previous fall for the corresponding period at Kew since 1866 is 16·75 in. in 1890–91.

IN the August issue of *Man* Major R. Burnett describes a remarkable tribe in the neighbourhood of Mosul, popularly known as "Slaveys," which possibly represents the Bedouin Solibala, of which the Russian writer Ponafidina gives an account in his "Life in the Moslem East." The "Slaveys" are a desert tribe

supposed to be the direct descendants of the Crusaders. Their dress consists of gazelle skins, and they have a cross marked on their backs. "They have no religion and no marriage laws: very poor and peaceable. It is considered unlucky to kill one of them, and they help the wounded." The Mohammedan Arabs despise them and call them "wild dogs." They are known for the shortness of their stature and the great length of their spears. They are the carpenters, blacksmiths, and doctors for man and beast among the Bedouin, and live in tents made, not of hair, but of skins. They may possibly be connected with the Negrito race which Sir Percy Sykes describes in the recently published second edition of his valuable "History of Persia."

IN the *Museum Journal* for March last we find an account of an interesting series of marble vases from Ulua Valley, Honduras, which are of such an unusual type that they have given rise to much speculation. The Ulua culture, like other ancient American cultures, is without date, but it was certainly contemporary with the ancient Maya Empire, as well as with other cultured races that flourished in Mexico, Panama, and Costa Rica. The technique and ornamentation of these vases are certainly remarkable. Attempts made by Mrs. Zelia Nuttall to interpret the symbolism are sharply criticised by the writer of this paper, who remarks:—"It would be as useless to speculate concerning the symbolism of all this ornament as it would be to guess at the service for which the vessel was designed. We are at liberty to assume that so elaborate and refined an object had a ceremonial function, and that its symbolism corresponds to ideas associated with its use, but its interpretation is quite beyond our reach."

THE issue of the Journal of the Royal Society of Arts for July 15 is devoted to a lucid paper on the development of Bombay by Sir G. Curtis. The position of the city, including originally seven islands, had long exposed portions of the site to inundation, and the enormous commercial development necessitated extension. These difficulties are being met in various ways, the principal being the reclamation of the area known as Back Bay. The chairman, Sir W. Sheppard, commented on the magnitude of the proposed series of undertakings:—"With regard to cost, there were few works in India—indeed, none of the precise kind described—which had cost, or been expected to cost, so immense a sum as thirty millions. Even in Europe so large a scheme would be considered wonderful, and he believed the renovation of Paris cost only about half the proposed expenditure on Bombay." But this has not deterred the Governor, Sir G. Lloyd, from pressing on the work, and the people of Bombay evidently believe in the project, as they showed by raising a local loan of nearly ten millions.

DR. D. F. CURJEL has obtained records of the weights at birth of 1849 normal Indian infants; the average is 6·5 lb. This compares not unfavourably with that of European infants. The conclusion is that the high infantile mortality which prevails among Indian children is largely due to unfavourable post-natal conditions. The same author has also inquired into the duration of reproductive life of Indian women. The average age of the onset of puberty was 13·63 years, and the average duration of reproductive life 32·14 years, both of which do not differ materially from the limits for European races (Indian Journ. of Med. Research, vol. viii., No. 2, pp. 363 and 366).

EXPERIMENTS have been conducted by Major J. C. G. Kunhardt and Asst.-Surg. G. D. Chitre on the eradication of plague infection by rat destruction. The observations made strongly support the view that the reduction in the rat population, resulting from plague itself (which attacks rats), is the main factor in bringing infection to a natural end, and that it yet remains to be seen if the destruction of rats by any artificial means is capable of producing or accelerating the same result. A number of rat poisons was tested, but none was found better than barium carbonate, of which three grains is a fatal dose for the rat. It is best made into a bait with dough of some grain-flour (the best grain was found to be bajri, *Pennisetum typhoideum*), and without any addition in the form of fat, sugar, condiments, etc. (*Indian Journ. Med. Research*, vol. viii., No. 3, 1921, pp. 409, 446).

IN the July issue of *The Fight against Disease*, the organ of the Research Defence Society, excerpts are given from an address by Sir John Rose Bradford at Oxford on "The Place of Experiment in the Science and Art of Medicine." Dr. Drury communicates notes on an "experiment," made by Nature herself eighteen years ago, on the protection against smallpox afforded by vaccination. In a school at Ossett there were 169 children, of whom 92 were vaccinated and 77 unvaccinated. Smallpox was introduced by a scholar, and no fewer than 37 of the 77 unvaccinated contracted the disease. Only 5 of the 92 vaccinated contracted it, all of whom had been vaccinated ten or more years previously. None of the 14 scholars who had been re-vaccinated took the disease. In the class into which the disease was first introduced (Standard IV.) all the vaccinated escaped and every one of the unvaccinated promptly took the disease.

DR. PERKINS gives in the Journal of the Torquay Natural History Society (vol. iii., No. 1) an account of his investigations on the food of trout caught in the Torquay reservoirs in August and September. He found that the nature of the food in the reservoir fish was very different from that of river fish. The latter appeared to be feeding on aquatic insects only, to contain much less food, and to be in an inferior condition generally. In the reservoir fish the food seemed to be composed mainly of such land insects as happen to fall accidentally on to the surface of the water under the stress of weather conditions. Dr. Perkins is of the opinion that this difference in the nature of the food is due to the fact that in the reservoirs the aquatic insects are limited in species, and the rarity or absence of some forms specially favoured by trout is the result of the extermination of the insect by the fish. The reservoir trout have thus to fall back on a source of food denied to the river fish. In a single trout's stomach Dr. Perkins found no fewer than forty-six species of land insects, the

majority of which were beetles. No insect seems to come amiss to the trout as an article of food, and so important is this source of food-supply that the active rising of the fish is dependent on the activities of the land insects at the time.

In the Journal of the Torquay Natural History Society (vol. iii., No. 1) Mr. Harford J. Lowe gives an interesting account, compiled from original notes and manuscripts, of the excavation work accomplished by the Rev. J. MacEnery at Kent's Cavern in Devonshire in the early years of last century. MacEnery was the pioneer worker at this famous cave, and by his energies and enthusiasm dug up huge collections of the remains of extinct British mammals and of the work of early man in Britain. Unfortunately, the results of his work seem to have been overshadowed by the publications of his more illustrious contemporary Buckland, with whom he was in constant communication, and, although published after his death by Vivian in 1859 and Pengelly in 1869, the work accomplished by MacEnery never seems to have received due recognition and reward. It is interesting to learn from Mr. Lowe's paper that, in spite of the prejudices and antagonistic opinions prevailing at the time, MacEnery had more than a suspicion of the important bearing of his work on the antiquity of man in Britain. MacEnery's collection was, unfortunately, dispersed by auction at his death, and students of this subject will be grateful to Mr. Lowe for the information which he gives as to the ultimate destination of part of it at any rate. Some of it found its way to the Jardin des Plantes, Paris, the British Museum, the Athenæum Museum, Penzance, the Plymouth Institution, and possibly to Bristol, while some at least remained at Torquay.

We have received the first number of a new serial publication, the *Australian Museum Magazine*, issued by the Australian Museum under the editorship of the director, Dr. C. Anderson. The object of the magazine is to put the museum into more intimate relationship with its owners, the public of Australia, by keeping them in touch with the work that it is doing, by making its collections better known, by giving accurate and up-to-date information in simple language on the natural history and geology of the Commonwealth, and, in general, by showing how the museum can be of service to the nation and, conversely, in what ways the public can help the museum. Thus in this first number are to be found articles on the scope, work, and management of the Australian Museum and on museum groups, in which some insight is given into the technical work that has to be done in the preparation and exhibition of specimens, in addition to interesting accounts of Blackfellows' pictures, white ants and other Australian insects, snakes, crawling jelly-fish, and the lure of the big nugget. This experiment of rendering an account of its stewardship by the Australian Museum is one that might well be tried by other national museums. The museum is making a praiseworthy effort to stimulate a healthy pride among the people of Australia in their national institution and to secure that measure of interest and sympathy so essential if it is to develop its activities to the fullest extent. We hope the public will respond by leaving nothing undone that will place the Australian Museum among the first of its kind.

The publications of the Naturhistorischer Verein der preussischen Rheinlande und Westfalens for the years 1913–19 have now reached us, and show the remarkable activity of the society even during years of war. The volume of the Verhandlungen for 1916 was completed in 1918, and the paper used and the mode of illustration show little falling-away from the high standard of 1914. As has happened in so many countries, deterioration sets in under the conditions following the war; but even now the plates do not suffer. The work of the society is largely geological, but chemists and biologists are concerned with August Thienemann's detailed "Physikalische und chemische Untersuchungen in den Maaren der Eifel" (1913–14). The marked differences in the plankton of the various crater-lakes depend on the distribution of oxygen in the waters. The mineral springs entering from the volcanic rocks show marked differences of composition in different lakes. The author of these researches adds in 1915 a study of the midge larvæ inhabiting the Maare, and in 1917 he describes the vertical zoning of the plankton in the Ulmener Maar. In 1916 F. Goebel gives a morphological description of the well-known district of the Ruhr, on the east bank of the Rhine. F. Winterfeld, of Cologne, publishes (1918) an illustrated paper on "Der aufrechte Gang des Menschen," in which he finds no room for pessimism. He concludes that "der Mensch der Zukunft wird im geistigen Sinne des Wortes aufrecht gehen, sich aufrecht halten, gehoben durch seine Ideale." We cannot help remembering the melancholy fact that hitherto physically upright man has been preserved mainly by the compulsion of military service. Enough has been said to show the range of research embodied in these undeterred publications of the war-time.

Under the editorship of M. Maurice Solovine, Messrs. Gauthier-Villars et Cie are issuing a collection of "Maîtres de la Pensée scientifique" in order to keep alive the memory of the advances made in the past by the great masters in every branch of science, whether these masters are French or of other nationalities. The volumes are $6\frac{3}{4}$ by $4\frac{1}{2}$ in., contain about 100 pages, and are issued at about 3 francs each. Huygens's "Lumière," Clairaut's "Géométrie," Carnot's "Réflexions," and d'Alembert's "Dynamique" are amongst the works issued, some of which extend over two volumes of the series. D'Alembert's work is reproduced from the second considerably enlarged edition which appeared in 1758, fifteen years after the first. It furnishes a good example of the clear and logical methods of development of a subject which were adopted by French scientific writers of a century and a half ago.

In the July issue of *Science Progress* Prof. W. L. Bragg gives a summary of our knowledge of the dimensions of atoms and molecules. He points out

that the kinetic theory of gases allows us, from measurements of the viscosity or the heat conductivity of a gas, to calculate the mean distance of the centres of two molecules of the gas apart when the molecules are in contact, that the constant *b* of Van der Waals furnishes another estimate of the distance, and that the two estimates agree in giving about 2×10^{-8} cm. for the mean radius of hydrogen and helium molecules and about 3×10^{-8} cm. for the mean radius of the molecules of argon, nitrogen, oxygen, carbon dioxide, and other gases. With these figures as a basis, X-ray crystal analysis then gives the relative positions of the atoms in the molecule of the material analysed. So far the most careful analysis of crystals of potassium chloride has, however, failed to reveal any structure corresponding to the KCl molecule. Each K atom is surrounded by six Cl atoms at equal distances from it. For chlorides the distances vary with the metal in the molecule, are large, -3 to 5×10^{-8} cm., for the first elements of a "period," and decrease to a limit $1{\cdot}3$ to $2{\cdot}7 \times 10^{-8}$ for the last elements.

MANY methods of harmonic analysis have been given of recent years. We need mention only the methods of Perry, Silvanus Thompson, and Russell. The question has now come prominently forward in connection with the disturbances induced in telephone and radio stations by the harmonics in the currents carried by overhead power lines. The power station engineer wants the manufacturer to guarantee that the electric generator he purchases from him shall give a pure sine-shaped wave of electromotive force. As it is impossible to make the machine give an absolutely pure sine wave, limits have to be fixed on the magnitudes of the amplitudes of the harmonics in the wave. Hence harmonic analysis is a necessity. In the Journal of the Institution of Electrical Engineers (vol. lix., p. 491) Mr. A. E. Clayton gives a *résumé* of the ordinary methods and two schedules for "harmonic analysis" by means of selected ordinates. One goes to the 25th harmonic and the other to the 13th. In the one case the assumption is made that no harmonic higher than the 25th is present, and in the other that there is none higher than the 13th. Seeing that in actual electromotive-force waves there is an infinite number of harmonics present, and as only a limited number of ordinates are drawn, we should have little confidence in results obtained by a "schedule."

THE Cambridge University Press will publish shortly "The Calendar," by A. Philip, the purpose of which is to provide a concise and popular summary of the history and construction of the Gregorian calendar, with special reference to the reform of the calendar and the fixing of the Easter date.

Our Astronomical Column.

BRIGHT OBJECT NEAR THE SUN.—Prof. Campbell, Director of the Lick Observatory, reports by telegraph an object brighter than Venus that was seen on August 7 3° east of the sun and 1° south. The message states that there is no doubt of the object being a celestial object. It is either a comet or a nova. The former appears more probable, owing to the distance from the Galaxy, where most novæ appear.

VARIABLE STARS.—The Bruce 24-in. photographic telescope at Arequipa has been used for taking spectrograms of the Large Magellanic Cloud, in which Miss Leavitt some years ago detected several variable stars (Harv. Ann., vol. lx., No. iv.). Miss Cannon, in Harv. Bull. No. 754, gives the spectral type and magnitude range of eight of them as follows:—No. 884, Mc, 11·4m. to 15·5m.; No. 900, M, 12·2m. to 13·6m.; No. 2257, K5, 12·4m. to 13·2m.; No. 2435, K5, 10·8m. to 11·7m.; No. 2447, K5, 12·0m. to 12·8m.; No. 2622, K5, 13·2m. to 14·0m.; No. 2822, Mc, 9·8m. to 10·6m.; and No. 2882, Mb, 11·0m. to 13·6m. The numbers are from Harv. Ann., vol. lx. It is satisfactory to find that such faint stars are within the reach of spectroscopic analysis.

Mr. Stanley Williams contributed a paper to Monthly Notices, R.A.S., vol. lxxxi., p. 332, on the star B.D.+44·994°, which he announced as a peculiar variable, possibly of the Cepheid type. Miss Cannon gives its spectral type as Ma; and Miss Leavitt has identified 150 images of the star on plates taken during the last twenty years. Its normal photographic magnitude is 10·5m., but on seven dates it was 10·2m.; it is very red (Harv. Bull., No. 754).

C. Hoffmeister, director of Sonneberg Observatory, noted on May 30 last, while observing Reid's comet, an 8th magnitude star that is not in the B.D. Its position for 1855·0 is 7h. 57·0m., N. 58° 14′, and it is shown on the Harvard plates. Prof. Küstner has examined the original observations of the B.D., and finds that a star of 9·5m. was observed in the place on February 19, 1858, but not seen again, so it is probably variable (*Astr. Nach.*, Circ. 22). In the same circular H. Fuss announces that B.D.+42·3351°, 7·5m., has the large proper motion of +0·065s., +0·16″.

MR. FLINT'S PARALLAX OBSERVATIONS.—Publications of Washburn Observatory, vol. xiii., part 1, contains the details of the series of meridian observations for stellar parallax made at Washburn between 1898 and 1905 with the Repsold meridian circle of 12·2 cm. aperture, fitted with a travelling-wire micrometer.

The programme extended from declination −35° to +90°, and embraced stars from magnitude 1·5 to 2·5, with some binaries and stars of sensible proper motion. A screen with thin metal slats rotating about their axes like the laths of a Venetian blind was used to equalise magnitudes, 7·0m. being made the standard. Two comparison stars, one preceding, the other following, the parallax star, were used in each case.

The mean probable errors of a single observation of unit-weight and of the final parallax of each star are 0·214″ and 0·031″ respectively. The last quantity is of about three times the size of the probable error in the best recent photographic determinations, showing that the meridian method cannot compete seriously with the photographic. Still, the experiment was well worth making, and the research will occupy a place in the history of the subject, so that it is well to have the details published. The list of parallaxes contains 124 stars, of which the deduced relative parallax is negative in thirty-five cases. The values for Algol and Castor, 0·122″ and 0·167″, are about three times the accepted values, while that of Altair, 0·071″, is only about one-third of it; but in many cases there is better agreement.

The Universities and Research.[1]

By PROF. J. JOLY, F.R.S.

THE argument for research in universities rests upon the broad basis of the value of the intellectual progress of mankind. I think I am correct in saying that most men who have adopted a life of research, or have made research the object of their special interest, have acquired their intellectual ideals in the days of their college life. It is through the university that the young man comes into contact with the investigators of his time, and it is their example and teaching which affect his future life. If his teachers are without interest in research the student learns indeed the text-book, but the enthusiasm to create new knowledge is not implanted in him. Whatever his intellectual capacities may be, he passes from his university but an ordinary member of the educated public. What he might have accomplished, and could have accomplished, had he found himself in a creative atmosphere during his student days remain entirely unknown.

I do not think that any other argument for the cultivation and promotion of research in universities need be stated. If the investigation of Nature is good in itself; if its effects are beneficial to our race; if it is desirable that we should advance in knowledge from generation to generation, then we should see to it that our brilliant young men get the chance of taking up this career in the service of mankind. There is, as I say, no answer to this argument unless we assail its basis and determine that obscurantism is the better thing and enlightenment the worse.

Great universities have done great good. They have also done great harm. Their inertia, their opposition to development, to following the evolutionary changes of their times, constitute their principal offence. Even to-day I hear in my own university surviving voices expressive of distrust in science as an educational subject; doubts as to the propriety of including science as a primary subject in the university curriculum; regrets that the so-called "great" or "fundamental" subjects of education—*i.e.* classics and mathematics—should no longer form the only road to fellowship.

Such views on science are the natural outcome of an upbringing in the traditions of the older educational methods. To attain the forefront of classical criticism or of mathematical advance is a more difficult task than to reach the exploratory front of a branch of modern science. And not only is it more difficult to arrive at the forefront; it is also more difficult, when the forefront is attained, to find work of any probable benefit to mankind. Only the most brilliant scholars and the most original minds can prevail. Compare these conditions with those attending research in any of the newer domains of modern science. No sooner has the student mastered the principles of his subject than he finds himself approaching an unknown territory. Everywhere he sees the words "Not known" written up, and any one of these innumerable avenues to knowledge is for him to tread if he so pleases and is equal to the task.

The contrast is remarkable. The older scholar, who has spent his days turning over the thoughts of others and the time-worn records of past efforts, gradually arrives at the fatal conclusion reached by the wisest of men: "There is nothing new under the sun." He has passed a lifetime of solid work and seen but little come of it. Must not the younger workers be branded by superficiality?

As regards the subject of expense, there is no doubt that, contrasted with blackboard and chalk, modern scientific apparatus and scientific laboratories are expensive. It is discouraging to compare British outlay with American outlay upon research in universities. We are supposed to have learned a lesson by the war. Let us hope it will bear fruit when business revives in this country. Meanwhile this lesson has placed a heavy demand upon the universities. For every branch of technology is crying out for research workers, and the universities cannot supply them. The fact must be faced that the day of research has come in all the scientific professions and in every domain where technology or business comes into contact with the natural laws governing production and economy.

The reactionary sitting in senate, council, or board, who would close the university to these demands, may indeed effect economies, but his economies are at the expense of the vitality of his university, of its very existence as part of the living, breathing life around it. It is a cheap road, but it leads to stagnation, decay, and death.

Perhaps the most striking feature of American universities, as viewed by the British visitor, is the prevalence of research and the lavish provisions made for its prosecution. It extends into every branch of university work. Special stress is, however, generally laid upon certain subjects. What these subjects are seems to depend upon the initiative and forcefulness of particular teachers of eminence, either past or present, who have been associated with the university. The great Research School of Education in Chicago, of which Prof. Dewey seems to have been the chief originator, may be cited. Highly organised and carefully staffed elementary and high schools are here attached to the university for research in pedagogy. The Nutrition Laboratory of the University of Illinois, founded by Prof. Grindley, is another instance. The State universities are very often in close touch with agricultural research, and not only benefit agriculture thereby, but also extend the influence of the university over the State by the valuable assistance given to the agriculturist. In our own country there is no class of the community more in need of such university influence than the agricultural. It is—in Ireland—not only ignorant of science, but also strongly antiscientific. This applies almost as much to the so-called educated classes as to the small farmer.

For research in experimental science and chemistry and natural science extensively equipped departments are provided in all the great American universities and technological institutes. The equipment is on the most lavish scale. Everything possible seems to be done for the student.

There is one subject which I must refer to: the compulsory presentation of Latin or of Latin and Greek by students entering the older universities. I know we are a long way from reform in this matter, but its influence upon the present subject is sufficiently important to necessitate a reference to it.

As regards research in the physical and natural sciences, there is no doubt that the compulsory study of dead languages is injurious—indeed, seriously injurious. This is so for two reasons. It serves to keep out many from the universities, and it demands of the science student hours of toil which would be better spent on living tongues, which would help him later on to extend his scientific reading. I am every day in contact with brilliant young men whose minds are absorbed in the interests of physical or natural science, but who cannot read a German book, and

[1] From a paper read before the Congress of the Universities of the Empire at Oxford on July 8.

read a French one only with difficulty. These young men have spent many school years during which the study of Latin and Greek absorbed about one-third or one-fourth their total available study hours. What have they got for it? They cannot read a Latin author or a Greek author at sight. It is true that without their Latin they would not have attained the degree of the University of Dublin. The pro-classic says their minds are the better for it. Well, I freely admit that much mental training was involved, but I do not admit that a sound study of French and German would not have done for them just as much—nay, more.

The reproach that many students fail as research workers, while it has some foundation in fact, is not a fair one, for it ignores the educational value of even elementary research. I believe the outlook of a student who has carried out one single research of an elementary kind is different from that of one whose outlook is derived solely from the text-book and the examination. He learns first-hand the mental point of view of the investigator. He gets ideas of scientific truth and of the legion of errors which lie in wait around it as may in no other way be acquired. He sees the plausible, *prima facie* conclusion break down under the control experiment or in the light of the inexorable requirements of other participating laws of Nature. A new conception of the use of mathematical analysis and of careful observation is created in his mind. More generally he learns the necessity of "thinking round" his subject.

These things he learns in some degree even if he is only of average capabilities. If he is one of the higher spirits the interest of the work seizes on him and calls out every power, latent and developing, wherewith he is endowed. These higher spirits work out their own destiny. I shall not dwell on the ways of genius, but rather upon research as an instrument in the education of less gifted minds. I turn, therefore, to the interesting question: "Is it possible to teach research successfully?" To teach its methods and its spirit to the average student, whether of science or of the "humanities"?

The answer I would give unhesitatingly is "Yes." I would be careful to define that this does not imply the genesis of an original thinker from ordinary material. But it implies just as much as when we say we can teach students mathematics.

I plead, therefore, for lectures in our universities devoted exclusively to studies in research, and I would admit to these lectures students of both junior and senior standing, *i.e.* the beginners in science as well as those working for the Ph.D. as now instituted in all British universities.

Of course, I am not now referring to systematic lectures in this or that branch of science. These are essential to the training of the average student. I mean something different. I would define research lectures as mainly relating to the professor's own experience and to that of his assistants and co-workers, each worker contributing one or more lectures to the university course in research. Their subject-matter would relate to the objects aimed at by the research, the difficulties attending the work, and how they were surmounted. Such discourses might be supplemented by others of an historical or retrospective character. These might in some cases be delivered by honours students, and would refer to classic researches of the great masters. For recounting these, experimental illustrations should be given. The inspiration to be derived from such retrospective studies will be known to all who have read the original memoirs of great investigators. There need be no extra call upon the professor's time. He would simply substitute these for part of his existing routine lecture work.

The professor is at present too much tied down by routine courses. There is a sort of idea prevalent that it is not fair to his class that he should tell them of his own work, but that this should rather be kept for the academy and for the outside world. Well, I think it *is* fair; and I believe that with reasonable usage the best thing he can do for his class is to tell them of his own work. If this were admitted in high quarters it would be more often carried out. I can imagine nothing more stimulating than a few lectures each term on the work progressing in the laboratory of the professor and his co-workers, for not only is the student brought into touch with the making of knowledge, he is also sure to receive the story in the language of fresh and enthusiastic interest.

I am aware that occasionally and at scientific associations within the university such discourses are delivered. I would make them a part of the sessional work of the university. If not legally obligatory on the professor, it should be morally obligatory on him to contribute a few such lectures every term, or at least every session. I do not think it would impose additional labours on him. Fresh from his work, but little rearrangement would be required, and his facts would be ready marshalled in his memory. Nor would the telling of his ideas fail to react upon the lecturer—to his benefit and to the elucidation of his subject.

The one central result aimed at is the presentation of research as something of paramount importance. It should stand for the highest goal of university effort, for, in truth, success in the making of knowledge is the crown of all human endeavour, and as such the student should be taught to regard it. Teach him this one great ethical truth, and whatever else he may accomplish or fail to accomplish in his student days, he will enter on his life's work an enlightened and a valuable citizen, not only of his own country, but also of the world.

International Exploration of the Upper Air.

By C. J. P. CAVE.

A MEETING of the International Commission for the Exploration of the Upper Air was held at Bergen on the invitation of Prof. V. Bjerknes, president of the commission, in the week ending July 30. The commission was appointed by the Meteorological Conference held at Paris in 1919 to continue the work, in connection with the International Meteorological Committee, which was carried on with marked success from 1896 until the beginning of the war, and with which is specially associated the names of the late Teisserenc de Bort, Rotch, and Assmann, under the presidency of Prof. Hergesell.

The following countries were represented at Bergen: Belgium, Denmark, France, Great Britain, Holland and the Dutch East Indies, Italy, Japan, Norway, Spain, Sweden, and Switzerland; and the meetings were also attended by a number of prominent meteorologists from Norway and Sweden. The proceedings opened with a reception by the president and Mrs. Bjerknes at the Meteorological Office of the Geophysical Institute, and with a lecture by J. Bjerknes on recent advances in the study of the Polar front and its relation to a succession of cyclones. It was arranged that the morning sessions should be devoted

to scientific communications presenting new points of view, and the afternoons to administrative details. This arrangement was disturbed in the course of the week in order to provide more time for administrative questions.

The sessions for scientific discussions were opened by a paper by Prof. V. Bjerknes giving theoretical explanations, on the basis of wave motion at the mutual boundary of two discontinuous media, of the series of phenomena which had been set out by his son, representing the result of observations upon the Polar front in cyclones. This was followed by a paper by Sir Napier Shaw on the structure of the atmosphere and its thermodynamics, to suggest a thermodynamic basis for the study of convection in the atmosphere, and the transformations of energy associated therewith. A paper by L. F. Richardson directed attention to the necessity for studying pilot-balloon observations in relation to the continuity of mass, a subject which in spite of its importance has hitherto not received adequate treatment. Prof. van Everdingen gave an account of a method of obtaining regular observations of pressure, temperature, and humidity in the upper air by means of aeroplanes, using a balloon meteorograph with the usual clock-work drum; such observations had been carried out on upwards of 340 occasions in the past year at Soesterberg and other stations in Holland. S. Fujiwhara, of Tokyo, discussed turbulent movements which are to be observed in clouds, and their relation to eddies in water. Dr. W. van Bemmelen, of Java, gave an account of comprehensive results of great importance of observations of wind in the upper atmosphere up to 30 kilometres, obtained at the observatory at Batavia. H. Köhler, of Holdda, discussed the study of the condensation of water vapour in a cold atmosphere into ice crystals and super-cooled water drops, and the effects which may be attributed to very small quantities of chlorides.

L. F. Richardson discussed the application of the geostropic principle to winds in the stratosphere. Dr. A. de Quervain, of Zurich, brought up proposals for the establishment of a geophysical observatory at the terminus of the Jungfrau railway, at a height of 3600 metres, which received the cordial commendation of the meeting. P. Schereschewsky, of the Corps of Mines, Paris, explained the method of determining the winds in the upper air by means of sound-ranging applied to detonators carried by pilot balloons, a method which is applicable alike in clear and cloudy weather. R. Sekiguti, of the Observatory of Kobe, explained the application in forecasting of isobaric charts for the level of three kilometres. Col. L. Matteuzzi, director of the Meteorological Service of Italy, presented an atlas of the principal cloud forms, and explained a method of applying the periodicity of barometric oscillations to the anticipation of barometric distribution in the future. O. Devik, of Tromsø, described a new method of observing balloons and its application in forecasting. G. I. Taylor gave an account of the result of his investigation of turbulence in the atmosphere and its symmetric propagation in the three dimensions. M. Dongier discussed the observations of temperature and wind at the Eiffel Tower and the discontinuities which they disclose. J. Bjerknes directed attention to the unique accumulation of observations of the upper air during the war which had been communicated to the president by the countries on both sides, and gave illustrations of the observations on selected occasions in the study of the method of the Polar front. P. Schereschewsky gave an account of some new methods of forecasting, and the proceedings of the meetings for scientific discussion were concluded with a paper by L. F. Richardson on ideal arrangements of stations on the map for the purpose of numerical computations for forecasting.

The business meetings were devoted largely to the development of a scheme for the collection, compilation, and publication of observations in the upper air on an international basis, in continuation, with such modifications as experience has suggested, of the international scheme which was agreed upon at Petrograd in 1904 and supported by subventions from Government organisations of nineteen countries. The outline of a proposal was agreed upon, and the president was requested to report it to the meeting of the International Meteorological Committee to be held in London in September. The commission adopted resolutions in favour of a geophysical observatory on the Jungfrau, and also appointed a sub-committee to deal with the question of the anomalies in the audibility of the sound of explosions, which was also the subject of a communication by Dr. de Quervain.

It was noticeable that the commission devoted the greater part of its attention to the mode of dealing with the observations of the upper air based upon the supposition that there should be twenty-four days in the year on which balloons for sounding the highest layers of the meteorological atmosphere, including the stratosphere, should be sent up in a sufficient number of countries to secure a general representation of the whole. At present the number of observations is extremely limited, and the reorganisation of the observations would need the support of meteorological institutes in many parts of the world. Beyond pointing out the urgent necessity for such observations over the sea, the technique of which had already been worked out by Teisserenc de Bort and the German meteorologists, but which had not become international in any sense, the commission confined itself to a general invitation to the meteorological organisations of the globe for co-operation on the international days.

An account of the proceedings of the meetings would be incomplete without reference to the hospitality of the citizens of Bergen. It will be remembered that the greater part of the inner town was destroyed by a disastrous fire five years ago, and it has not yet been rebuilt; all the hotel accommodation was required for tourists, and the delegates to the meeting were all entertained with cordial hospitality by the foreign Consuls and the citizens of Bergen, and also honoured by an official dinner given by the municipality, at which the Chief Burgomaster presided. The municipality also placed its ancient and picturesque Council House at the disposal of the commission for the meetings.

A Small Brinell Hardness Testing Machine.

HARDNESS, as recent correspondence in NATURE (vol. cvi., pp. 377, 440, 534, 599, 662, November, 1920–January, 1921) has shown, is a subject of interest to both the engineer and the physicist. Whatever may be the exact physical significance of the term, there can be no doubt that measurements of this property, or group of properties, are of increasing practical importance. In the Brinell method of measuring hardness, as commonly applied, a steel ball of diameter about 1 cm. is applied to the surface of the test piece under a load of the order of 3000 kg., and the size of the resulting impression is measured. In practice

the use of a ball of this size is limited to specimens not much less than one-tenth of an inch in thickness and half an inch in width. In 1913 the necessity arose for the accurate determination of the hardness of the walls of small-arm cartridge-cases at different positions along the length. The thickness of wall, diminishing in some cases to about one-hundredth of an inch near the shoulder, is quite insufficient for the application of the usual Brinell test. Accordingly, a machine was designed and constructed by Messrs. H. Moore and R. Mather for the Research Department, Woolwich, in which very small balls with correspondingly small loads could be employed. A description of this machine has been given by Mr. Moore in

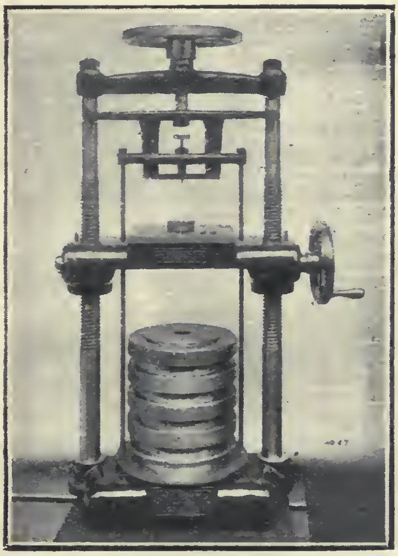

FIG. 1.—A small Brinell hardness testing machine.

the Proceedings of the Institution of Mechanical Engineers of January, 1921. It was designed to permit of great latitude in the dimensions of the test specimen, of the use of various sizes of ball from 1 mm. diameter upwards, and of loads from 5 to 100 kg. The first machine was in continuous use during the war, and was the subject of a secret patent (Craig, Moore, and Mather's patent), which, however, has now been published. The illustration (Fig. 1) shows a simplified form of the machine constructed by Messrs. Alfred Herbert, Ltd., of Coventry.

The machine stands upon a base-plate furnished with levelling screws. This plate supports two vertical threaded columns which carry the table for the reception of the specimens to be tested. By turning the hand-wheel at the side of the machine the table may be set at the required height. The load seen in the lower part of the photograph is composed of a set of graduated cylindrical weights totalling 50 kg. It is carried by the loading stirrup, to the upper portion of which is attached the ball-holder. The ball is fastened to the ball-holder by india-rubber solution so as to render the changing of balls an easy matter. The most important point in the design of the apparatus is the method by which the load is transferred from the cross-head of the machine to the specimen under test. By turning the hand-wheel at the top a non-rotating screw of fine pitch can be raised or lowered. The lower end of the screw carries a suspension stirrup, which is prevented from rotating by arms bearing against the columns, and from this suspension stirrup is hung the loading stirrup by means of a ball-and-socket joint. When the stirrup is lowered gently, so that the ball rests upon the specimen, the loading stirrup becomes free and disconnected from the suspension stirrup. At this stage the whole of the weight is upon the specimen, there being no parts in friction or rubbing contact. The upper hand-wheel is then turned back to take the load off the specimen, which can now be removed for the purpose of measuring the diameter of the impression by means of a high-power microscope with graduations of 1/200 mm. on the graticule. The hardness numbers are calculated as in the ordinary Brinell test, the load being divided by the area of the impression, and are directly comparable with the usual Brinell numbers when a load proportional to the square of the ball diameter is employed.

The impressions are so small as to be scarcely perceptible to the eye, and tests may be made on parts of delicate mechanisms without injury to the part tested. Loaded small-arm cartridge-cases may be tested without removal of bullet or charge. The hardness of wire at successive stages of drawing can be measured. Cutlery blades, however thin, may be tested, and the hardness of a cutting tool may be determined close to the cutting edge. Interesting applications of this microscopic Brinell test have been made in the exploration of strain-hardening, for when a metal object has been unequally strained the distribution of strain will usually be indicated by differences in hardness from point to point.

Attention may also be directed to the micro-Brinell apparatus developed by the Ordnance Department of the U.S. Army (Bureau of Standards, Bulletin 16, 1920, p. 557). This has been used with a load of 15 kg. for 30 seconds upon a ball 1/16 in. in diameter for measuring the hardness of individual crystals or small aggregates in annealed carbon steels.

H. S. A.

The Coal-mining Industry.

By PROF. H. LOUIS.

THE July issue of the *Quarterly Review* contains an article upon the recent coal dispute by Dr. Arthur Shadwell, to which he has given the somewhat unfortunate title "The War of the Mines." Dr. Shadwell points out at the beginning that this dispute was really not a war, and that there was in reality no need at all for a difference, which might have been arranged by mutual concessions, to have degenerated into industrial strife. He recognises that this was not a case of the men striking against any arbitrary action of the employers, but was rather an expression of their irritation at the inevitable development of the economic situation, and he states clearly and definitely the only remedy: "There is only one way out—the way of work. Other nations in a similar position have taken it; they are at work, and working hard. Here less work is being done than ever before."

It is pointed out quite correctly that the mining industry is distinguishing itself above all others in the readiness with which it resorts to industrial strife, and that the real cause of many of these difficulties, and the basal reason for the present grave position of the coal industry, are to be sought in the Minimum Wage Act of 1911, which is accurately described as "the first instance of a minimum wage established by Parliament in an industry in which the workmen are well organised and able to protect themselves."

Dr. Shadwell is undoubtedly right in saying that the demand for this Act arose on account of the existence of "abnormal places" in coal-mines—that is to say, places in which men cannot make normal wages even though they work up to the normal standard, and that these conditions are due to natural causes which can be neither controlled nor foreseen. He appears to accept the Minimum Wage Act as the only means of meeting the difficulty, but in this view experienced coal-miners are not likely to concur. It should be perfectly possible to devise means other than this Act, which unfortunately encourages slack work, without the grave drawbacks which the Act has brought in its train, but such other methods must be founded on mutual confidence between masters and men.

It must be admitted that this antecedent condition does not exist; masters have in the past been only too ready to look upon hard work or successful work on the part of the men as a fair pretext for cutting piece rates, and this action has sown in the men's minds the seeds of the suspicion that they cannot rely upon the masters for fair treatment in the case of abnormal difficulties. Colliery managers to-day are, no doubt, wiser, and have learnt to appreciate the fact that it is to their advantage, no less than to that of the men, that the latter should be in a position to earn high wages, provided, of course, that they give a commensurate amount of work in return. The old suspicious feeling, however, remains, and it has been responsible for the introduction of legislation which has probably done more harm to the coal industry than any other single step that can be named.

Dr. Shadwell devotes considerable attention to the discussion of the proposal for a national pool, but he evidently fails to see the real object underlying the proposal. He says that "it is impossible to maintain that there is anything impracticable or economically ruinous in pooling or amalgamation," and cites Sir George Elliott's old proposal to amalgamate all the collieries in the kingdom into one concern. He fails to see the difference between voluntary amalgamation and compulsory pooling, which latter would necessarily bring in a large number of collieries that are no longer able to produce coal for less than its market price. He suspects, indeed, that the object with which the pool was put forward was political, but does not appear to see the real motive underlying the scheme. As a matter of fact, all the proposals put forward for a considerable time past by the Miners' Federation, the Minimum Wage Act, repeated shortening of the hours, nationalisation, the pool, as well as the less openly avowed tendency to restrict production wherever possible—all these have one and the same underlying object, namely, to keep the largest number of men in the industry.

This object has been only too successful; the coal-miner to-day produces only two-thirds of what he did fifteen years ago, so that for an equal production the number of men employed in the industry is proportionately greater. Obviously, the larger the number of men employed in the industry the greater the political power of the Federation, because it thus obtains control of a larger number of votes and of larger monetary contributions. This gain to the Federation is, however, dearly purchased by the decrease in the efficiency and prosperity of the industry, and obviously such a road can only lead to ultimate ruin and destruction. No industry can prosper if it has in its ranks more men than it can legitimately maintain. The object of nationalisation was to support out of the pockets of the taxpayers the mines incapable of producing economically; the object of the pool was to support them at the expense of the mines that could pay their way. Both schemes were political, in the sense that their object was to keep a number of men in the industry who were working at a loss, and to devise means by which that loss might be made good by someone else. If Dr. Shadwell will consider the effects of the proposed pool upon the mining industry of the country as a whole in the above light, he will readily see why both mine-owners and the Government have offered such strenuous opposition to it.

Botanical Papers from Pennsylvania.

TWO parts of the Journal of the Botanical Laboratory of the University of Pennsylvania recently received (vol. iv., No. 2, and vol. v., No. 1) contain a number of interesting papers. Dr. D. W. Steckbeck has studied the comparative histology and irritability of sensitive plants. The majority of the highly sensitive species are natives of subtropical and tropical America, and their most widespread irritable response is the nyctitropic or "sleep-movement." The author suggests that the phenomenon of propagation of stimuli is centred in the endodermis, the cells of which contain a greater or less number of crystals of oxalate of lime, the number, regularity of shape, and degree of restriction to the endodermis increasing with the increase of sensitivity shown by the plant; the climax is reached in the two highly sensitive plants *Mimosa pudica* and *Biophytum sensitivum*. Each crystal is surrounded by a protoplasmic sac, threads from which pass through adjacent cell-membranes so as to form continuous protoplasmic connections throughout the endodermal tissue; the crystals with their protoplasmic connections are regarded as the special conducting lines for stimuli. The cells of the pulvinus of the leaves are found to contain aggregation bodies, resembling those described by Darwin and others, increasing in amount and complexity with increasing sensitiveness; these show contraction and aggregation changes under stimulation. They are proteinaceous in nature, and all contractile changes resulting from external stimuli seem to be due to changes primarily in the protoplasmic sac by which each is surrounded, secondly in the aggregation body itself, and finally in the amount of liquid these may absorb or give off.

Dr. J. S. Hepburn and Dr. E. Q. St. John describe the results of their investigation of the active digestive agent in the liquor secreted in the pitchers of the pitcher-plant (Nepenthes). Does digestion result from the action of a protease secreted by the pitchers or is it due to bacterial action? The authors found that liquor taken aseptically from unopened pitchers was sterile, but liquor in partly opened pitchers which were free from insects contained bacteria. The slowness with which bacterial digestion of the protein occurred shows that bacteria play a secondary *rôle* in the digestion of insects; the leading *rôle* is undoubtedly played by the protease of the pitcher liquor. The enzymes contained in the bodies of the insects may also assist in digestion.

Miss Alice M. Russell gives a comparative study of the macroscopic and microscopic structure of some hybrid Sarracenias and their parent species. Sarracenia is the genus of pitcher-plants native to swampy districts in Atlantic North America from Labrador to Florida, and several natural hybrids have been reported. The hybrid forms are found to be inter-

mediate, in comparison with the parents, in almost all details, namely, shape of leaf-pitcher and lid, colouring, size and shape of flower (though the flower of the hybrid is inclined to be larger and more showy than the parent), and size and shape of the petals. The intermediate relation also extends to microscopic details, such as character of cells of the epidermis, number of stomata, and characters of the internal tissues.

Dr. H. W. Youngken has studied the comparative morphology, taxonomy, and distribution of the Myricaceæ (bog-myrtles) of the eastern United States. The author finds that the infesting organism in the characteristic root-tubercles is an Actinomyces, and he has also observed it in the cells of the fruit-wall; after the fall and decay of the fruit it will again make its way into the soil and infect roots of other Myricas. Coccus-like forms, believed to be involution forms of the infesting Actinomyces, were found in the pitted wood-vessels, and apparently indicate the pathway taken by the parasite in order to reach the fruit-wall.

Miss Margaret Henderson describes the results of a comparative study of the structure and saprophytism of the Pyrolaceæ and Monotropaceæ in relation to the Ericaceæ (heaths). The author suggests that the two former families differ from the Ericaceæ only in their gradually increasing saprophytism and in those characters which go hand-in-hand with this, namely, loss of green colouring matter, reduction from shrubs to herbs, reduction of leaves to scales, increase in the number of seeds, and the reduction in their size and in the number of cells of the endosperm and embryo. Similar degradation changes occur in the orchid and gentian families, and the author therefore supports the view which would regard the Pyrolaceæ and Monotropaceæ, not as distinct families, but as representing subfamilies of the Ericaceæ.

The Claude Process for Ammonia Synthesis.

In the issue of the *Revue scientifique* for May 28 M. Georges Claude gives an interesting account of his process for the synthesis of ammonia, depending on the use of pressures approaching 1000 atmospheres. The work of compression of a gas at constant temperature varies as the logarithm of the pressure, so that if the work of compression from 1 to 200 atm. is 2·3, that from 1 to 1000 atm. will be only 3, or at most 3·5, if the diminution of compressibility at high pressures is taken into account. At high pressures, however, the percentage of ammonia in equilibrium with hydrogen and nitrogen will be greatly increased. Claude announced in 1917 that his experiments indicated that the yield could be increased from about 13 per cent. at 200 atm. to more than 40 per cent. at 1000 atm., the temperature being the same in both cases. A production of 6 grams of ammonia per gram of catalyst an hour, as compared with 0·5 grams in the Badische process, is attained. Whereas it is necessary at 200 atm., employed by the Badische Co., to circulate the gas several times over the catalyst, and to separate the ammonia after each circulation, it is sufficient to circulate only three or four times at 1000 atm. The volume of the apparatus required for the same production is only about one-tenth that required at 200 atm. pressure. The main source of difficulty in working at high pressures is the evolution of heat, which is 25 to 50 times greater than in working at 200 atm. The difficulty is then, not to conserve the heat of reaction to make the process autothermic, as is the case in the Badische method, but to eliminate this heat. The Claude apparatus has been operated with success at La Grande Paroisse with a unit producing 1·25 metric tons of ammonia per day, and a larger unit, for 5 tons per day, with a compressor dealing with 700 cu. m. of gas per day, has recently been put into operation with success.

The percentage of ammonia after passing the catalyst is about 25 at 1000 atm., as compared with about 6 at 200 atm. The partial pressure is therefore 250 atm., as compared with about 12 atm. at 200 atm. total pressure. The vapour tension of liquid ammonia at atmospheric temperature being from 7 to 8 atm., it will be seen that this is negligible in the gas obtained by the Claude process, but most appreciable with the gas obtained by the Badische process. It is sufficient, in Claude's apparatus, to pass the gas through coils immersed in cooling water in order to separate practically all the ammonia, and the residual gas, after separation of liquefied ammonia, is sent directly, without further compression, to a second catalyst chamber. Three or four catalyst chambers suffice to convert the gas into ammonia. In the Badische process, on the contrary, it is necessary to wash out the ammonia with water under pressure, requiring a complicated apparatus and expenditure of work to bring the gas again to 200 atm. after mixing with fresh gas, and 15 catalyst chambers are required. It is also necessary to use heat to separate the ammonia gas from the solution so obtained, whereas in Claude's process the liquefied ammonia is merely allowed to evaporate, producing cold which can be utilised.

The Claude process, which offers great possibilities in the synthesis of ammonia and in the utilisation of atmospheric nitrogen, is to be installed in England. The patent rights have been acquired by the Cumberland Coal and Chemicals Co., who are to erect a works in the centre of the coke-oven district in Cumberland.

Field-work of the Smithsonian Institution.

The Smithsonian Institution has just issued its annual Exploration Pamphlet, describing and illustrating its scientific field-work throughout the world during 1920. Twenty-three separate expeditions were in the field carrying on researches in geology, palæontology, zoology, botany, astrophysics, anthropology, archæology, and ethnology, and the regions visited included the Canadian Rockies, fourteen States of the United States, Haiti, Jamaica, four countries of South America, Africa from the Cape to Cairo, China, Japan, Korea, Manchuria, Mongolia, Australia, and the Hawaiian Islands. The pamphlet serves as a preliminary announcement of the results obtained, though many of the expeditions will be more fully described later in the various series of publications under the direction of the Smithsonian Institution.

Dr. C. D. Walcott, secretary of the Smithsonian Institution, continued his geological work in the Cambrian rocks of the Canadian Rocky Mountains in the region north-east of Banff, Alberta. The work was hindered considerably during July and August by forest fires and by continuous stormy weather in September, but the particular questions involved in the season's research were settled satisfactorily, and some

beautiful photographs of this wild and rugged region are shown in the pamphlet. Other geological field-work was successfully carried on in various States of the United States by members of the staff.

In astrophysical research the institution was unusually active. Through the generosity of Mr. John A. Roebling, of New Jersey, the Smithsonian solar observing station located on the plain near Calama, Chile, was moved to a mountain peak near by, where the observations will be unaffected by dust and smoke; and a new station was established on the Harqua Hala Mountain, Arizona, probably the most cloudless region in the United States. From daily observations of the radiation of the sun at these two widely separated stations it is hoped to establish definitely the value of "solar constant" observations in forecasting weather. Dr. C. G. Abbot, director of the work, also describes the successful operation on Mount Wilson, California, of a solar cooker devised by him. With this apparatus it was possible, using only the sun's heat, to cook bread, meat, vegetables, and preserves.

Mr. H. C. Raven represented the Smithsonian Institution on an extensive collecting expedition through Africa from south to north. Although many difficulties were encountered, among others a railway wreck in which two members of the expedition were killed, Mr. Raven shipped to the institution much interesting zoological material which was greatly needed for purposes of comparison in working up the famous Roosevelt and Rainey collections already in the National Museum. Many interesting photographs of the animals, the natives, and the country itself are shown in this account and in that of Dr. Shantz, who accompanied the expedition as botanical collector. In Australia a Smithsonian naturalist collected, through the generosity of Dr. W. L. Abbott, specimens of the fast-disappearing remarkable fauna of that continent, while Dr. Abbott himself secured for the National Museum a great number of plants, birds, and other natural history material in various regions of Haiti. A number of other zoological and botanical expeditions are briefly described and illustrated.

In anthropology Dr. Ales Hrdlicka, of the National Museum, conducted extensive investigations in the Far East with the objects of continuing the study of the origin of the American Indian, examining the oldest skeletal remains in Japan, furthering the interests of physical and medical anthropology in China, and studying the rapidly disappearing full-blooded Hawaians. The work was successful in every respect.

Dr. J. Walter Fewkes continued his archæological field-work on the Mesa Verde National Park, Colorado. During the field season of 1920 he excavated and repaired a remarkable prehistoric building, which he designates "Fire Temple" on account of the undoubted use of this structure by the Indians in connection with the worship of fire. The ruin is described and illustrated in the pamphlet.

The book concludes with numerous accounts of field-work among the American Indians by members of the staff of the Bureau of American Ethnology, Smithsonian Institution, including researches among the Hopi, the Papago and Pawnee, the Fox and Cree, and others; and archæological investigations of prehistoric aboriginal structures and dwellings in various regions of the United States.

University and Educational Intelligence.

OXFORD.—Two important elections to professorships have been made since the end of term. The vacant Drummond professorship of political economy has been filled by the appointment of Prof. David Hutchison Macgregor, Stanley Jevons professor of political economy in the University of Manchester, sometime professor of political economy at Leeds, and fellow of Trinity College, Cambridge. Prof. Macgregor is known as a writer and lecturer on industrial and philosophical questions, and has also done work in connection with the Board of Trade.

The Linacre chair of zoology and comparative anatomy, vacant by the regretted retirement of Prof. G. C. Bourne, has been filled by the appointment of Prof. E. S. Goodrich, fellow of Merton College, and hitherto professor of comparative embryology and Aldrichian demonstrator in comparative anatomy at Oxford. Prof. Goodrich enjoys a high reputation among zoologists, and his artistic attainments are also widely recognised. He is president this year of Section D (Zoology) of the British Association, and the address which he is to deliver at the forthcoming Edinburgh meeting is awaited by zoologists with keen interest.

The University has lately bought a large house in Mansfield Road, part of which will furnish the School of Geography with increased accommodation.

THE Board of Education has at last issued the long-awaited report of the Burnham Committee dealing with scales of salaries for *full-time* teachers in technical schools, schools of art, evening schools, and day continuation schools, in which the local education authority accepts responsibility for the salary scales. The report follows in natural sequence upon the reports of the other two Joint Committees, and is correlated especially with that of the Joint Committee on Secondary Schools. Teachers are graded as (1) principals, headmasters, or headmistresses, (2) heads of departments, (3) graduate assistants, (4) non-graduate assistants, and (5) instructors. For the graduate class the scale determined is 240*l*., rising to 500*l*. by annual increments of 15*l*., and for non-graduates 190*l*., rising to 400*l*. by annual increments of 12*l*. 10*s*. The corresponding figures for women are 225*l*., rising to 400*l*. by annual increments of 15*l*., and 177*l*. 10*s*., rising to 320*l*. by annual increments of 12*l*. 10*s*. For male graduates in the London area the scales are increased by the addition of 50*l*. to both the minimum and the maximum, corresponding additions being made also to the other scales. In order to attract highly trained teachers to the technical service, the local education authority may raise the minimum by 25*l*. and the maximum by 50*l*. in the case of a good honours degree or its technological equivalent. Further, other additions may be made in respect of post-graduate training and posts of special responsibility. It is possible, therefore, for a graduate teacher to secure a maximum salary of 650*l*. in London and 600*l*. in the provinces, with the opportunity of promotion to the higher grades. Under such conditions a real career is offered in the service to both men and women, and the Committee is to be highly congratulated on the satisfactory completion of an extremely difficult problem. The Committee regrets that it has been unable to determine scales for the other grades of teachers owing to the many and various types of schools and the wide divergence of local conditions. Local education authorities are asked, however, to formulate suitable scales by agreement, and it is pointed out that these scales should be comparable with those adopted for similar classes of teachers in the secondary schools of the area. The adoption of the report will influence the desired development in technical and scientific education, which depends so largely on the securing to, and retaining in, the service the best type of teacher. It is in this respect satisfactory to find that technical and commercial qualifications and other experience may be regarded as the equivalent of an academic degree.

Calendar of Scientific Pioneers.

August 11, 1857. Marshall Hall died.—A distinguished physiologist, Hall while practising in London as a doctor studied the circulation of the blood, and in 1832 made his important discovery of reflex action.

August 12, 1865. Sir William Jackson Hooker died.—Few men have done more to advance the study of botany than Hooker, who from 1820 to 1841 held the chair of botany at Glasgow, and from 1841 to 1865 was director of the Royal Gardens at Kew. His herbarium—an exceptionally rich one—was bought by the nation.

August 12, 1896. Hubert Anson Newton died.—Made famous by his study of meteors and his prediction of the memorable display of November 13, 1866, Newton from 1855 until his death held the chair of mathematics at Yale, and for a time he directed Yale Observatory.

August 13, 1907. Hermann Karl Vogel died.—One of the pioneers in the application of Doppler's principle to stellar spectroscopy, Vogel worked with Zöllner and Spörer, and from 1882 was director of the Astrophysical Observatory at Potsdam. In 1883 he published his first spectroscopic star catalogue.

August 15, 1758. Pierre Bouguer died.—A Royal professor of hydrography, Bouguer studied naval architecture, and to him we owe the term "metacentre." He accompanied Godin and La Condamine on the great meridian expedition to South America (1735-45), and is also known as the inventor of a heliometer.

August 15, 1852. Johann Gadolin died.—An early exponent of Lavoisier's views, Gadolin was one of the most distinguished scientific men of Finland. He was the first to introduce the term "specific heat."

August 15, 1856. William Buckland died.—The first reader in geology at Oxford, Buckland made many pioneering geological excursions, wrote one of the Bridgewater treatises, and in 1822 received the Copley medal for his discoveries in a cave at Kirkdale. He was for some years Dean of Westminster.

August 16, 1705. James Bernoulli died.—From 1687 until his death James or Jacob Bernoulli held the chair of mathematics at Basle. His lectures of 1691 contain the first published attempt to construct an integral calculus.

August 16, 1899. Robert Wilhelm Bunsen died.—Holding the chair of chemistry at Heidelberg for thirty-seven years, Bunsen, like Liebig and Hofmann, was a great investigator and an inspiring master. His important work included the study of gasometric analysis and the chemical action of light, the invention of the Bunsen battery, the Bunsen burner, a photometer, and an ice calorimeter, and with Kirchhoff in 1859 he began his epoch-making researches in spectrum analysis.

August 16, 1920. Sir Joseph Norman Lockyer died.—Originally a clerk in the War Office, Norman Lockyer became famous for his pioneering work in astrophysics. Simultaneously with Janssen in 1868 he devised and used a method of viewing the solar prominences in ordinary sunlight, and shortly afterwards discovered helium. Transferred in 1875 to the Science and Art Department, he was from 1885 to 1913 director of the Solar Physics Observatory at South Kensington. He was the founder of this journal, and has been described as "one of the greatest astronomers of all time."

August 17, 1856. Constant Prévost died.—Known for his geological studies of the Vienna basin and of volcanoes, Prévost in 1830 with Boué, Deshayes, and Desnoyers founded the Geological Society of France.

Societies and Academies.

PARIS.

Academy of Sciences, July 25.—M. Georges Lemoine in the chair.—E. **Borel**: The fundamental hypotheses of physics and geometry.—G. **Lemoine**: The mutual reaction of oxalic acid and iodic acid, iii. The influence of sunlight. The experimental difficulties are considerable, owing to the rise of temperature which necessarily takes place during the exposure. In round figures, it may be concluded that in sunlight the time of half-decomposition for a given temperature is 0·4 that found in the dark.—E. **Haug**: The dysharmonic folds in the mountains to the north of Toulon.—L. **Joubin**: Oceanographic cruises now being carried out. An account of the work allotted to France by the International Commission at Copenhagen and the researches already in hand.—F. **Widal**, P. **Abrami**, and E. **Brissaud**: Experimental researches on autocolloidoclasia by cold. Experiments on dogs have shown that immersion in cold water (2° to 3° C.) for periods of from fifteen to forty-five minutes produced changes in the blood identical in character with those due to anaphylactic and other forms of shock. The leucocytes were reduced in number, the leucocytic formula was changed, coagulation of the blood occurred in a shorter time, and the refractive index of the blood serum was lower. The effect was transitory, and the more serious symptoms of anaphylactic or proteid shock were not produced.—P. **Sabatier** and B. **Kubota**: The catalytic decomposition of allyl alcohol; action of various oxides. The catalysts studied were blue tungstic oxide, alumina, thoria, zirconia, uranous oxide, and manganous oxide. The gases evolved included carbon monoxide, hydrogen, carbon dioxide, ethylene, and propylene, the last-named being in the highest proportion. Propanal and acrolein were present in the liquid distillate.—P. **Humbert**: Formula of multiplication for the Kummer function $\Phi(\alpha, \gamma, x)$.—S. **Carrus**: Triple orthogonal systems.—L. **Amaduzzi**: A new property of feeble electrical conductors. A discussion of the interpretation of an experiment recently described by M. G. Reboul.—E. **Dubois**: The minimum potential of electrical discharge in hydrogen at low pressures.—L. and E. **Bloch**: Critical potentials and band spectra of nitrogen. The negative band spectrum of nitrogen appears at a higher potential than the positive spectrum, and a little higher than the ionisation potential generally attributed to this gas. It appears natural to attribute the positive band spectrum of nitrogen to the neutral molecule N_2 and the negative band spectrum to the positively charged molecule N_2^+.—F. B. **de Lenaizan** and L. **Maury**: The conductivity of the solution of cuprammonium citrate compared with that of copper sulphate. The two salts obey the law of Arrhenius, and the copper ion is free to the same extent in both.—A. **Boutaric** and M. **Vuillaume**: The flocculation of colloidal arsenic sulphide. The influence of the dilution and the quantity of the electrolyte.—J. **Barlot** and J. **Pernot**: Combinations of the halogen derivatives of mercury and thallium.—A. de G. **Rocasolano**: The variations produced by stabilisers in the catalytic power of electroplatinosols. Sodium protalbinate, sodium lysalbinate, gum arabic, and gelatine were the stabilisers used in these experiments; in all cases the catalytic power, as measured by the decomposition of hydrogen peroxide, was reduced.—G. **Andoyer**: An apparatus for the technical analysis of gases.—V. **Auger** and Mlle. M. **Vary**: Sulphonations in the presence of iodine. The results obtained by the sulphonation of benzoic acid and pyrocatechol in presence of iodine are not in agreement with the experiments of J. N. Ray and M. Lac Dey

as regards the production of the ortho-isomer.—H. A. **Brouwer**: The eruption of a hornblende andesite in the Malay Archipelago.—L. **Lutaud**: The post-Sahalian movements and their influence on the morphology in the pre-Riffian zone of the northern R'arb, Morocco.—P. H. **Fritel**: The discovery in Senegal of two fossil fruits belonging to the genera Kigelia and Nipadites.—M. **Romieu**: The eleocytes of *Perinereis cultrifera* (Grube).—R. **Herpin**: The origin and the *rôle* of the reserve cells of the general cavity in *Perinereis cultrifera* and *P. Marioni*, and the early differentiation of their eggs. The reserve cells probably arise from the lymphocytes, and have for their principal function the nourishment of the sexual products in course of elaboration. The development of the eggs is extremely slow, and requires more than a year.—M. **Mirande**: The extraction and the nature of the substance producing sulphuretted hydrogen in the seeds of certain Papilionaceæ. A protein has been isolated from the seeds of *Lathyrus sativus*. Heated with water to a temperature of about 40° C., there is a spontaneous development of hydrogen sulphide; after this reaction is complete the residue still contains sulphur.—Mme. Z. **Gruzewska** and M. **Fauré-Frémiet**: The localisation of the glycogen in the liver and the muscles of dogs fed with a view to the maximum production of this reserve.—E. **Grynfeltt** and Mlle. R. **Lafont**: Experimental porphyrinuria. Lesions of the kidney of the rabbit produced by sulphonal intoxication.—MM. **Desgrez**, **Bierry**, and **Rathery**: Some modifications of the blood-plasma and of the urine during fasting in diabetic subjects.—P. **Masson**: The nervous lesions in chronic appendicitis.

A Suggested Institute of Human Sciences.

IN the human sciences—those sciences which deal with the origin, the characters (physical, mental, and moral), and the activities of man: in other words, the anthropological sciences in the broadest sense of the term—co-ordination and co-operation are more essential than in almost any other branch of scientific research. This is due partly to the extent of the ground covered, and partly to the character of the subject-matter, which is frequently based upon a mass of data collected from a wide area. This necessity for co-operation, acting in conjunction with man's perennial interest in himself and his past, has led to the formation of a host of societies, each dealing with one or more branches of the subject. Some cover certain special aspects only—archæological, sociological, linguistic, psychological, and the like; others study man on a regional basis, and of these some cover the whole field more or less completely, as in the case of Asia and Africa; while still others confine themselves almost entirely to the archæological aspect, as in the case of the societies which deal with Egypt, Palestine, and the Mediterranean area.

The function of these learned societies in the main is fourfold. The societies serve as a gathering place for workers at which the latest results of research can be announced and discussed; they provide libraries which in theory contain books and periodicals not otherwise readily accessible to their members; they act as the publishers of the work of their members, which, on the ground either of its specialist character or of its brevity, is not suitable for publication elsewhere or in book form, thereby assisting further in disseminating the results of scientific investigation; and, lastly, they further the interests of their subject by the promotion and organisation of research and by pressing its claims to support upon the public. There has been considerable variation in the measure of success with which these functions have been performed; but, speaking generally, as the affairs of the principal learned societies which deal with human studies are in the hands of those who have attained distinction in their subjects, they lead the way and exert a not inconsiderable influence upon the lines of development of further investigation.

Those, however, who are concerned with the administration of these societies are well aware that the position is not entirely satisfactory. There is very little co-operation between societies, although a few welcome, but tentative, steps in this direction have been taken. Not only does this restrict undertakings which for financial or other reasons are beyond the resources of a single society, but it also leads to a certain amount of overlapping. Most societies have a library; where several societies deal with cognate subjects, in certain sections the same books and periodicals appear in each. This is a waste of both space and money, whether the library is augmented entirely by purchase or in part by exchange. There is also a waste of the time, energy, and money of the worker. A paper dealing with a certain specific subject may appear in any one of half a dozen or more publications, and it is impossible to know in which of a number of libraries a certain book may be found. In one case a scientific worker who wished to make use in his laboratory of a certain book long out of print visited nearly every scientific society in London before he ran it to ground. He then had to join that society in order to borrow the book.

There is also the question of catalogues and bibliographies. Owing to the cost of printing, any catalogue which is to be of use to the members who live at a distance, and cannot visit the library, is an impossibility, while a bibliography of current literature on comprehensive lines seems equally impossible without greater co-operation than has been secured up to the present.

In addition to the cost of maintaining libraries,

under the present system heavy expenditure is imposed upon each society by the necessity for providing suitable and adequate accommodation for meetings and lectures.

It is unnecessary to labour these points, which must be familiar to many. The difficulties do not date from to-day or yesterday, but at the moment they are more acutely felt. Under financial stress the activities and usefulness of scientific societies are being restricted. Increases in subscriptions do not counterbalance increase in costs. Individual workers also suffer; in many cases they have to confine their membership to the society to which their work is most closely related, thus restricting their outlook and their knowledge of current work.

It would, therefore, seem desirable to cast about for some remedy which might remove or mitigate these disabilities. This might be found in the union of a number of societies dealing with this group of studies to form an Institute of Human Sciences, housed in one building and governed by a supreme council, each society retaining such a measure of autonomy under its own committee as is consistent with the common aim. Considerable economies could then be effected by pooling the respective libraries, thus avoiding unnecessary expenditure on duplicating books, and to a certain extent by pooling the staff. The amount saved might be applied to increased expenditure on the library, on cataloguing, or on bibliographical work, for which the facilities would be greatly extended by the collection of the greater part of the material and the association of a number of specialists in various branches of study within the four walls of one building. The extent to which the various societies would be fused into one institution must depend upon circumstances; but it would probably be a gain if the publications were standardised and issued in series. It would not follow as a matter of course that each member would receive all the series; the issue would be confined to such only as he required. In fact, the issue of publications might well serve as a basis for regulating the amount of the subscription payable over and above the common fee of the institute admitting to the privilege of attendance at meetings, the use of the library, and other services.

That such an institute would greatly increase the resources at the disposal of the scientific worker is self-evident. Not only would he be brought more closely into touch with those investigating different aspects of the same problems as he himself is investigating, but he would also benefit in other ways. Although scientific investigation is becoming increasingly a matter of specialisation, yet in the anthropological sciences the interrelation of the different branches of study is becoming closer as the need for synthetic treatment is more fully appreciated. No student of the human sciences can afford to neglect results obtained in fields other than his own. Under the present system few have the time at their disposal to attend the meetings of all the societies with the work of which they should be acquainted, or to go through all their publications, even if these are accessible. Given an institution under one roof, organised to meet this need of the worker, with a common library and a common staff, and provided with an adequate bibliographical system, and he should have no excuse if he failed to obtain all that he required.

By a combination such as is indicated science would benefit in at least two directions. Under the control of a supreme council, which from its constitution would be in a position to survey the whole field, research could be organised on a scale and with a certainty of direction which have not yet been attained, while the financial assistance which such an association of interests might hope to command would be considerable. Further, the influence which this body could bring to bear upon public opinion would be such as far to outweigh anything of which the individual societies appear capable at present, however desirable or necessary the objects which they urge from time to time in connection with matters of public interest.

In education it is now becoming generally recognised that, in addition to the study of physical and mental characters, the data of the human sciences have an important bearing upon many of the subjects of the curriculum of both universities and schools, and can be applied with advantage in teaching even quite small children. At present the educationist or the teacher who is not acquainted with the results of specialist research outside the four corners of his own subject is at a loss in which direction to turn for trustworthy guidance. Such guidance it would be one, and that not the least important, of the functions of the institute to provide.

Finally, although this scheme of amalgamation, for obvious reasons, must, with possibly a few exceptions, be confined to societies now housed in London, there is every reason to hope that

local societies throughout the country could participate to some degree. The local archæological societies have done good work, but in the present state of our knowledge there is great need that their work should be standardised and given direction on a more or less common basis. This object might be attained by a system of affiliation and co-operation, more close than any now existing, with some central body such as the institute here suggested.

Astrology.

(1) *The Mediaeval Attitude toward Astrology, particularly in England.* By Theodore Otto Wedel. (Yale Studies in English. No. lx.) Pp. vii + 168. (New Haven: Yale University Press; London: Humphrey Milford: Oxford University Press, 1920.) 10*s*. 6*d*. net.

(2) *Opera hactenus inedita Rogeri Baconi, Fasc. v. Secretum Secretorum cum glossis et notulis; Tractatus brevis et utilis ad declarandum quedam obscure dicta.* By Fratris Rogeri. Nunc primum edidit Robert Steele. Accedunt versio Anglicana ex Arabico edita per A. S. Fulton. Versio retusta Anglo-Normanica nunc primum edita. Pp. lxiv + 317. (Oxford: Clarendon Press.) 28*s*. net.

THE attitude of man towards Nature may be said to have two stages—the "magical" and the "scientific." In the former, man lives in a world surrounded by other ill-defined beings and powers. From time to time he finds, or thinks he finds, some way to make these subserve his will, but he has as yet no apprehension of a constant relation of cause and effect. In the later, scientific stage—which first presents itself clearly to our view in the Ionian philosophers of the sixth century B.C.—a belief has arisen in natural law, in an invariable relation of cause and effect. Perhaps the most important step in the journey towards this belief was the discovery of the regularity in the movements of the heavenly bodies. The laws that these movements exhibit had long been the subject of organised observation in the Mesopotamian civilisations from which the Ionians inherited a wealth of data. But the Greeks had a passionate, almost an instinctive, belief in natural law, though few such laws had been demonstrated. Perceiving the majestic and regular recurrence of heavenly phenomena, they learned to predict them. They saw, too, that winter and summer, seed-time and harvest, day and night, and all the other broadly cyclic events of life, could be brought into some sort of relation with the heavenly cycle. Outside and beyond these there were, indeed, innumerable less regular and unpredictable phenomena, for there was as yet no biology, no chemistry, practically no physics, and scarcely any mathematics. What more reasonable than to attribute a relation between the phenomena observed to be cyclic and those the laws of which were yet unknown? Natural laws there must be, and the field of the known was but extended into the unknown. Thus astrology was born.

Later a definite geocentric spherical system of the universe was introduced—a system that held its own right down to Copernicus and Galileo and beyond. The earth was surrounded by those mysterious concentric spheres in which the stars and planets held their place—the heavenly bodies considered by the greatest of the philosophers to be eternal and divine. Spatially the universe was limited; outside the outmost sphere was nothing; within the inmost sphere was the little world on which we live. To such a view the theory of astral and planetary control of our world was attractive, satisfying, well-nigh inevitable. It needed only verification, but verification was not the strong point of the scientific system of antiquity, still less of the Dark and Middle Ages which followed. The belief in the value of astrology thus remained almost universal from Greek times until the seventeenth century. It is unfair to regard it as a superstition. It is but a discarded and untenable scientific hypothesis.

Astrology, however, had a foe, and that foe was the Church, or rather the Churches. But the opposition of the Churches must not be accounted to them for scientific righteousness; rather it was the other way. The Churches were ever insistent on man's dependence on God. How, then, could man's existence be regulated by the action of the stars that were but God's creatures? Yet as time went on the opposition of all religions, Christian and other, gradually weakened. It became evident that even God Himself worked through agents, and why should not these agents be the stars that He had made? Thus room was made for the acceptance of astrological belief, which from patristic times onward gained steadily on men's minds. In the twelfth and thirteenth centuries, as the great Arabian revival of learning penetrated to the West, astrology became a highly elaborate science; by the fifteenth century, with the ebb of the scholastic movement, it had become a widespread obsession that infected alike the university, the council chamber, the law court, and the physician's consulting-room.

(1) The general history of this extraordinary

error is outlined by Mr. Wedel with a wealth of learning and an aptness of illustration that are a credit to American scholarship. His little volume betrays an enormous amount of research presented in an attractive and succinct manner that is a model for work of this kind. Especially praiseworthy is the logical and efficient distinction between material necessary for his narrative and the equally important material, needed by the specialist for verification and reference, that is rightly relegated to his ample notes; it is a distinction which is all too rarely made. Mr. Wedel is to be congratulated on a very able and readable contribution to the embryology of science.

(2) A much more difficult, though perhaps less thankful, task has been performed by Mr. Robert Steele. His edition of the version of the pseudo-Aristotelian "Secretum Secretorum" used by Roger Bacon, with notes by the father of English science himself, is a definitive contribution to our knowledge of the medieval attitude towards phenomena. This volume forms the fifth and largest fascicule of Mr. Steele's fundamental and valuable series of the hitherto unedited works of Roger Bacon. These works appeal perhaps to few readers, yet they are of permanent value as among the earliest documents of the re-birth of science.

With our present standards of historical and textual criticism it is at first incomprehensible that a great intellect like Bacon's could have taken this debased Arabian work for a treatise of Aristotle. With our standards of scientific verification it is equally incredible that such data as this work presents could make any appeal save to a confused and obfuscated intellect. Yet an appeal it did make, and for precisely that reason the work is of great interest, for by studying it and works like it we may reasonably hope to learn something of the mental processes with which "science" in our sense made its appearance in the modern world. These notes of Bacon were made at the turning point of his career, just before he passed from the pre-scientific to the scientific stage. He never freed himself from his belief in astrology, nor could any man entirely reject this doctrine while the geocentric theory held full sway. But Roger enunciated principles of observation and experiment which, in other hands, ultimately rendered astrological theory untenable. He never developed an adequate standard of textual criticism, but he made a strong appeal for the systematic study of languages, he formulated methods for such study, and he made remarkable and interesting attempts at grammatical analyses. These efforts of his, in other and more fortunate hands, led to a scientific treatment of languages and of texts.

Roger Bacon stands as one of the heralds of the dawn of science, yet he has suffered much, and still suffers, from misunderstanding and neglect. Some of his most interesting works are still unprinted, and their publication is one of the several important pieces of work that must be achieved before any adequate and continuous history of science can be written. Yet the editing of such works is by no means easy, for it requires, on the one hand a very special training, and on the other a wide range of different kinds of knowledge that are very rarely combined in one individual. It further demands a degree of patient endurance of toil that is rare even among professional scholars; and, lastly, it calls for an indifference to the material reward for such prolonged labours that is perhaps rarest of all. Every one of these qualities the editor of this fascicule exhibits in abundant measure; his introduction and notes are scarcely less valuable than the text itself. We can but hope that Mr. Steele will be spared to complete the task that he has undertaken—a task for which very few besides himself are properly equipped.

It would be ungracious not to mention also the valuable translation from the Arabic text by Mr. Fulton with which the volume is enriched. The book is a peculiarly fine example of the skilful, accurate, and scholarly printing which the Clarendon Press has taught us to expect from it.

CHARLES SINGER.

Physical Chemistry, Pure and Applied.

(1) *A System of Physical Chemistry.* By Prof. W. C. McC. Lewis. (In three vols.) Vol. ii., *Thermodynamics.* Third edition. (Text-books of Physical Chemistry.) Pp. viii + 454. (London: Longmans, Green, and Co., 1920.) 15*s.* net.

(2) *The Determination of Hydrogen Ions.* By Dr. W. Mansfield Clark. Pp. 317. (Baltimore: Williams and Wilkins Co., 1920.) 5.50 dollars.

(3) *The Physico-Chemical Properties of Steel.* By Prof. C. A. Edwards. Second edition, thoroughly revised. Pp. xii + 281. (London: Charles Griffin and Co., Ltd., 1920.) 21*s.* net.

(4) *Die Reaktionen des freien Stickstoffs.* By Prof. W. Moldenhauer. Pp. viii + 178. (Berlin: Gebrüder Borntraeger, 1920.) 26 marks.

(1) PROF. LEWIS'S "System of Physical Chemistry" has been reviewed in these columns on two previous occasions, in September, 1916, and in May, 1919. Only a brief notice is

therefore required of the third edition of the second volume of the series. The principal additions that have been made deal with the e.m.f. method of determining the transport number of an ion, as employed by MacInnes and Parker, the work of Richards and Daniells on thallium-amalgam cells and of Tolman on centrifugal cells, American work on ionic activity, experimental work in support of Donnan's theory of membrane-equilibrium, and the work of McBain on colloidal electrolytes. Much of this new material is described in the words of the original investigators, as has already been done in earlier parts of the book.

(2) The determination of hydrogen-ions has become a very important section of physical chemistry, especially in its application to biological problems. The fact that Dr. Clark's book on this subject has been produced from the Research Laboratories of the Dairy Division of the U.S. Department of Agriculture is one indication of the practical application of the various methods of measurement which the author describes. These include the use of indicators, of hydrogen and calomel electrodes, and a few supplementary methods. The applications of these methods are so numerous that it is almost impossible to describe them adequately in any single volume; the chapter which deals with these applications has therefore been written in the form of a classified bibliography, the detailed references for which occupy 64 pages of the text.

A noteworthy feature of the book is a chart showing the colour of eight different indicators at nine hydrogen-ion concentrations, covering in each case the change from the alkaline to the acid coloration. The frontispiece is a photograph of Prof. Sorensen. The book is likely to prove of great value either to the physical chemist or to the biochemist who wishes to take up the very fascinating and fertile branch of study with which it deals.

(3) The appearance of the second edition of Prof. Edwards's "Physico-Chemical Properties of Steel" affords an opportunity of directing the attention of the readers of NATURE to a valuable book which has not been reviewed previously in these columns. A book with this title may be criticised either as a contribution to metallurgy or as an application of physical chemistry to a group of technical problems. As the author is a metallurgist, the reader will expect to find the technical side of the work well developed, and he will not be disappointed.

The physical chemistry is more open to criticism: thus a paragraph on "allotropy" (a generic term covering at least three distinct phenomena) is not a satisfactory substitute for a clear description of the phenomena of isomorphism and polymorphism; the idea of "crystal bricks" is so far obsolete that it should surely be replaced by some account of the theory of space-lattices; it is impossible, even on the authority of Ewing, to accept the suggestion that rotating the "bricks" through an angle of 180° could possibly give rise to twinning—perhaps an angle of 90° was meant.

A few verbal errors have escaped correction in this edition, and the lettering of some of the diagrams has been reproduced by a process which leaves much to be desired in the matter of legibility. The micrographs, on the other hand, are a most attractive feature of the book, and none of them are more effective than those which the author has produced to show the formation of twinned crystals and of slip-bands as a result of mechanical strain in metals.

For the physical chemist Prof. Edwards has provided a mine of valuable information, bearing on the application to metallurgy of his branch of chemistry. Even the student is now generally familiar with the iron-carbon diagram and the general relationship of this diagram to the properties of the carbon-steels; but it is equally true that the parts played by sulphur and phosphorus are not generally known, even to the teacher of physical chemistry. It is a great convenience to have the available information put together in a concise form by one who is thoroughly familiar with the practical and not always harmful effects of these important impurities. The effects produced by manganese, chromium, tungsten, aluminium, silicon, and vanadium are also described, as well as the properties of special steels, such as high-speed tool steels and a number of ternary steels. The two new chapters in the second edition deal with the more important methods of making hardness-tests, and the influence of constitution on electrical resistivity.

Whilst the reviewer is not competent to assess the value of this book as a contribution to metallurgy, he can assert confidently that no physical chemist who has to teach students of engineering or metallurgy can afford to be without it, and that the information which it gives will broaden the outlook of any student of physical chemistry who may read it.

(4) Prof. Moldenhauer's book on the reactions of free nitrogen does not profess to deal with physical chemistry, and an apology is perhaps needed for including it in this category; but the nature of the subject is such that the main chapters of the book are necessarily physico-chemical in character, dealing as they do with

the "fixation" of the element in the form of ammonia, cyanamide, cyanides, or oxidised compounds of various kinds. These processes, which occupy the latter half of the book, have formed the subject of an extensive literature in recent years, and no great novelty of subject-matter or treatment is to be looked for.

The earlier half of the book traverses less familiar ground, and it is a great convenience to have the data in reference to the activities of a very inert element collected together in a systematic form. The facts that lithium and magnesium form exothermic nitrides and that cerium and uranium burn with incandescence in nitrogen represent the kind of information that can be given to illustrate the properties of a gas which usually receives but scanty treatment even when the behaviour of hydrogen, oxygen, and chlorine is fully described. T. M. L.

The Realm of Man.

Principles of Human Geography. By E. Huntington and S. W. Cushing. Pp. xiv + 430. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1921.) 21*s.* net.

The Principles of Economic Geography. By Dr. R. N. Rudmose Brown. (Pitman's Economic Library.) Pp. xv + 208. (London: Sir Isaac Pitman and Sons, Ltd., 1920.) 10*s.* 6*d.* net.

THE almost simultaneous appearance of two educational works on geography bearing very similar titles is not without significance. It shows the pressure of circumstances leading to the further elimination from geographical teaching of the mere enumeration of facts which has long been felt to be a desideratum, and to substitute an exposition which may claim to be regarded as a statement of principles. The result is, at any rate, the publication of two very good books, which may be welcomed as forming an important contribution to the definition of geography as it is coming more and more to be apprehended in the higher teaching of the subject. They may both be looked upon as going far towards supplying what the present reviewer has long felt to be a want among geographical text-books—a physical geography in which the main stress is laid upon influences, direct and indirect, on human life connected with place, rather than upon that aspect of the subject which looks to geology as its natural development; that in which almost the entire emphasis is laid on the operations by which the earth's crust undergoes modification.

This conception of the meaning of the designation "Principles" in both books is more apparent in the larger of the two, that of American origin, the chapters of which all have titles, such as "Man's Relation to Physical Environment," "Man's Relation to Location," "Man's Relation to the Climate," etc., bearing this out. Both works, indeed, involve the statement of a good many mere facts of geographical distribution, but it would be pedantic to take exception to this as not in accordance with the titles. The selection of the facts given shows regard to principle in the singling out of those which it is most important to think of from the point of view maintained by the authors.

While both books may be described as, in a large measure, physical geographies of the kind indicated, they are, of course, not wholly so. Neither would adequately answer to its title if it were, for in both it is recognised that when influences on human life are considered as having the place relation that demands their inclusion in geography, facts derived from many sciences have to be reckoned with and focussed in varying degrees in different cases on particular problems. Further, it should be added that both books are written in a style of admirable clearness.

But it does not follow from what has just been said that no exception can be taken to the exposition of principles by the authors. The eagerness to substitute principles for isolated facts sometimes leads to rather hasty generalisation, which, it must be confessed, has long been an evil in geography. The failing may arise from an insufficiently disciplined desire to place geography on the footing of a science, which, it is thought, it cannot claim without having its own stock of this kind. It might, on the other hand, be pointed out that the very fact that it is so hazardous to frame generalisations aiming at strictly geographical content, and that the function of geography is rather to maintain the habit of looking round in all directions for influences connected with place, has the advantage of making each case a subject for special and comprehensive thought, which surely gives great educational opportunity. At any rate, the tendency to lack of due care in generalising cannot be denied, and there are, especially in the American work, too many evil consequences thereof. Probably most of the hasty statements of which complaint is made would mislead no competent teacher. Most of them result, one may be sure, from no misconception on the part of the authors, who have simply, while using plain language, failed to express exactly what they mean, or in some cases made too summary statements, which may be accepted as true when the necessary qualifications are supplied.

One illustration may be given. Comparing the climate of the Lofoten Isles with that of Verkhoyansk in the same latitude, "and no farther apart than Portland, Maine, and Portland, Oregon," the authors ascribe the differences solely to the influence of the ocean. One cannot but ask, if that is so: How are we to explain the great differences especially between the winter climates of Portland, Maine, and Portland, Oregon, or the fact that the average mean January temperature of Cape Hatteras (46° F.) is just the same as that of the Scilly Isles 15° farther north, although the Gulf Stream proper passes close by the cape with a mean winter temperature of 72° F., while the winter temperature of the water round the Scilly Isles is only about 50° F.? One has to go well into the book to find any recognition of the agency of the winds as an intermediary influence on temperature.

One of the excellent features of the book is the number of ingenious and thought-provoking exercises at the end of each chapter, but a good teacher might find it profitable also to supplement those exercises by asking his students to fill up the gaps in the generalisations which are, without doubt, complete in the minds, but not in the text, of the authors.

The smaller book, by Dr. Brown, has no illustrations, but the other has, in addition to views, numerous instructive diagrams and maps.

GEO. G. CHISHOLM.

Calculus for Students.

An Elementary Course of Infinitesimal Calculus. By Prof. H. Lamb. Third edition, revised. Pp. xiv+530. (Cambridge: At the University Press, 1919.) 20s. net.

THE merits of Prof. Lamb's text-books are so well known and appreciated that it is unnecessary to analyse or commend the present one, especially as it appears in its third edition. As the work of an experienced teacher, revised in the light of modern mathematics, the book affords a model, and suggests a few observations. Naturally, the influence of recent research is most evident in the first chapter, "Continuity." This contains a discussion of sequences, upper and lower limits, limiting values and infinitesimals, which we may presume to be the author's idea of what is suitable for the average student before starting upon the infinitesimal calculus. In the light of present knowledge it is a kind of indispensable minimum; but it will probably be found as much as can be comprehended by the type of student for whom the book is mainly designed. In any case, the inclusion of such a chapter is a significant mark of progress in the practical aims of mathematical teachers.

There are two points to which the author himself directs attention. The first of these is that, in dealing with series, he has confined himself mainly to power-series, and omitted the discussions of uniform convergence previously included. Remembering that this is an *elementary* course, we may acquiesce, if with some reluctance, in the author's judgment. The second point is that $\exp x$ is defined as a particular solution of the differential equation $dy/dx=y$. This is Clifford's procedure in his "Elements of Dynamic," and has everything to be said in its favour—assuming that the student begins the calculus at the proper time in his general course. All the properties of the function and its inverse can be deduced with great ease, and in a way that needs no amendment when the variable is complex. We rather regret that Prof. Lamb has omitted the complex variable altogether; Clifford's graph of $\exp i$, and its connection with the radian, do, in fact, interest quite average students when they are working at de Moivre's theorem and its consequences.

It would be easy to point out many features of the book which show the advantages accruing from the fact that the writer is an applied as well as a pure mathematician. One of these is the excellence and instructiveness of the diagrams; another is the variety of the examples; and as a third we may take the discussion of the linear differential equation $y''+ay'+by=0$ and those closely associated with it. It is possible to make the discussion as dull and mechanical as the most old-fashioned solution of a quadratic by completing the square; here we have a treatment which is really instructive, and illustrated by the right sort of examples.

It is curious to notice that nobody seems to have suggested a "standard" sequence of theorems in elementary differentiation, though every argument urged for such a thing in elementary geometry applies here with at least equal force.

G. B. M.

Our Bookshelf.

Map Reading. By G. H. C. Dale. Pp. vii+170+xx plates. (London: Macmillan and Co., Ltd., 1921.) 7s. 6d. net.

IT is stated in the introduction to this book that a map is at times as valuable as a rifle. One might go further and say that a knowledge of local topography may be as valuable as a bat-

talion. Unquestionably the best of topographical educations is surveying on the ground, which should form part of the instruction of all candidates for commissions in the Regular Army. Unfortunately such instruction has not always been given, and is, perhaps, out of the question for Territorials. Even so, instruction in map reading should be given mainly on the ground. There are, however, examinations to be passed in which questions are based mainly upon certain specified maps and conventional signs. Mr. Dale's book will be found of great assistance in this matter. It is clear and practical, and accompanied by good examples and questions.

The sequence of the book would have been improved by combining parts of chaps. i. and vi. in a separate chapter on finding position. A compass is rarely used for this purpose by an experienced map reader if the map in question shows much detail. This chapter might also have included grids, margins, and co-ordinates both geographical and rectangular. Such information as is given on these points is not very enlightening. For example, the position of the origin of co-ordinates and the direction and order in which they are given may, and doubtless will, vary according to circumstances.

The British soldier may have to accustom himself to many different styles of cartography. He should not be asked to memorise any particular conventional signs, but to study such different maps as he may have to use, and, above all, to educate his eye for country. Artificial and arbitrary differences such as those made in chap. iii. between "hills" and "knolls" would then be unnecessary.

Faune de France. No. 1. *Echinodermes.* By Prof. R. Kœhler. Pp. 210. (Paris: Paul Lechevalier, 1921.)

With the aid of a subvention from the Paris Academy of Sciences, a new fauna of France, of which the first part has been issued, has been prepared by the Fédération Française des Sociétés de Sciences Naturelles. Its object is to furnish naturalists with a handy means of identifying their captures. To this end each group is preceded by a key to the species, and the descriptions which follow are just enough to enable the first result to be verified. The fauna comprises land and fresh-water forms from France (including Corsica), Belgium, the Rhine province, and Western Switzerland, and marine forms within the limits of the continental plateau to a depth of about 300 metres and the corresponding pelagic region from the Sound to the Straits of Gibraltar, including the British Isles and the Western Mediterranean. The work, therefore, should be found useful by British naturalists.

For the Echinoderms no better authority could be desired than Prof. Kœhler, of Lyons. His nomenclature is up to date, his descriptions are to the point, and his illustrations, being, as a rule, from photographs of the actual specimens, are sufficiently indicative for a work within these limits. Some of the half-tone blocks are, it must be confessed, not very clear, and some of the borrowed diagrams are credited to wrong sources; thus Fig. 10, of a starfish, is not from Goodrich, but from the British Museum Guide; Fig. 68, showing the fascioles of a sea-urchin, is one of the numerous figures taken by Delage and Hérouard from the Echinoderm volume in the "Treatise" edited by Lankester. At the special request of the editors, Dr. Kœhler has gallicised the ordinal names. The historical confusion that has arisen from this common French custom is well known, and we have never grasped why such a name as "Les Forcipulosées" is any more intelligible than "Forcipulata"; it is not even French.

The Place-Names of Northumberland and Durham. By Prof. Allen Mawer. (Cambridge Archæological and Ethnological Series.) Pp. xxxviii + 271. (Cambridge: At the University Press, 1920.) 20s. net.

Prof. Mawer's work on the place-names of Northumberland and Durham has an interest which transcends its geographical limitations. Unlike most workers on this subject, he does not confine himself entirely to the linguistic side of the evidence. He is prepared to turn to topography, ethnology, or history for assistance or confirmation. For instance, he has tested, by a careful examination of topographical conditions, the theory that names ending in *ington* occur on high ground where the geological formation favours the finding of springs. As a result, he finds that the theory holds good in East Northumberland only, but that in the west of the county the water supply is dependent upon other factors. The tendency of the lines of investigation followed by Prof. Mawer will inevitably be to bring the study. of place-names into closer relation with cognate problems in ethnology and history, and to break down the isolation which has characterised even some of the best work on the subject in this country.

As a result of Prof. Mawer's very careful survey of the evidence for names recorded before the year 1500, and identifiable on the map, it would appear that the vast majority are Anglian. River names are Celtic, but "Cheviot" is the only recorded Celtic hill-name of note. Prof. Mawer concludes that the Anglian conquest was complete. The distribution of names with a Scandinavian element does not afford strong evidence of settlement except in two, or possibly three, cases. It suggests rather a movement from the sea up the great river valleys or from the more distinctively Scandinavian areas which lie to the south. Prof. Mawer's book lends added force to the plea for an organised survey of English place-names as a whole which he has made elsewhere.

Nuova Navigazione Astronomica: Le Rette di Posizione. Teoria—Applicazioni—Tavole. By Prof. G. Pes. Seconda edizione. Pp. lxxxiii + 127. (Genova: Regio Istituto Sordomuti, 1921.)

THE position-line method in navigation was first introduced by Capt. Sumner; it has greatly grown in favour, since it exhibits in a convenient manner all the information that a single observation of altitude is capable of affording. There have been a large number of nautical tables published with the idea of simplifying the application of the method to determine the position-line of the ship. The "Altitude Tables" of the Rev. F. Ball give the altitude for every degree of latitude, declination, and hour-angle. Other tables by Aquino are in wide use in America. Mr. Herbert Bell proposed some useful modifications of the plan of the latter in a paper in M.N.R.A.S., vol. lxxx., p. 72.

The tables of Prof. Pes are of a different form; the principal table is one of haversines (*i.e.* half versed sines), both the natural and logarithmic values being given to five decimals. The author assumes a point on the earth's surface near the estimated position of the ship, and calculates the hour-angle P, and the meridian zenith distance z_m of the observed body, the declination of which is δ. He finds an auxiliary angle θ from the formula (ϕ is the latitude of the assumed point)

$$\text{hav } \theta = \cos\phi \cos\delta \text{ hav P}.$$

Then

$$\text{hav zen. dist.} = \text{hav } \theta + \text{hav } z_m.$$

A set of four small tables with easily derived arguments enables the direction of the position-line to be determined.

The ship lies on a parallel line separated from the former by the difference between the observed and computed zenith distances.

Opinions will differ as to the relative merits of these rival methods of reduction, but at least it may be said that the method given in this volume is sound and fairly short. A. C. D. C.

A Textbook of Botany for Medical and Pharmaceutical Students. By Prof. J. Small. Pp. x + 681. (London: J. and A. Churchill, 1921.) 25*s.* net.

THERE has been little attempt at selection in this book, with the result that a great deal of material has been brought together, some of which the beginner will scarcely be able to use. Nevertheless the book is written with independent views, and will doubtless be of service to many. The illustrations are a prominent feature, but some of them are on too small a scale to be satisfactory; *e.g.* Fig. 67, the legend of which also contains inaccuracies, as well as the figure itself. Such figures as 330 and 913 leave much to be desired. The work touches on every phase of botany, with frequent reference to economic applications. The advisability of including in an elementary text-book such a highly speculative subject as the author's theory of geotropism is very questionable, especially since the statolith theory has received strong experimental confirmation from the work of Bose. In the chapter on heredity it is a mixing of conceptions to apply the term reduplication to the crossing-over of chromosomes. This book will probably find its greatest use as a work of reference for pharmaceutical students and as an accessory text for others. Notwithstanding the above criticisms, it is a welcome addition to botanical text-books.

Stella Maitland; or, Love and the Stars. By H. P. Hawkins. Pp. viii + 249. (London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., n.d.) 6*s.* net.

IN a foreword the writer intimates that her object is "to create a deeper interest in the fascinating subject of astronomy, under the conviction that, if once aroused, it can never fail to yield one of the greatest delights which it is possible for the human soul to experience." The aim is commendable enough, but whether it will be promoted by this rather crude mixture of science and romance must be a matter of opinion. There is no subtlety in the characterisation, and the powder is administered baldly in the form of star-lessons. M. Camille Flammarion's "Stella" appears far more successful, considered as a work of art. But it is a *genre* in which success is scarcely to be expected. It suffers from all the handicap of the novel with a purpose in its most acute form, and it can make an appeal only to minds of an unsophisticated type.

Vocational Chemistry: For Students of Agriculture and Home Economics. By Prof. J. J. Willaman. (Farm Life Text Series.) Pp. ix + 294. (Philadelphia and London: J. B. Lippincott Co., 1921.) 8*s.* 6*d.* net.

BOYS and girls in American agricultural high schools are the readers for whom this book is intended. The first part is devoted to the fundamental facts and principles of chemistry, whilst the second deals with the main chemical facts concerning plant and animal growth, cooking and cleaning, and with milk and its products. The early portion of the book is superficial, and not free from inaccuracies and ambiguities. There are many illustrations, some of which are rather trivial—*e.g.* "an open fire-place," "a herd of beef cattle"—and some are on pages far removed from the description in the text, no references being given.

The Moral and Social Significance of the Conception of Personality. By the late A. G. Heath. Pp. viii + 159. (Oxford: At the Clarendon Press, 1921.) 7*s.* 6*d.* net.

THIS essay was awarded the Green moral philosophy prize in 1914. The author fell in the war. The book is now published by his friends with the desire, we can well understand, to raise to a comrade a *monumentum aere perennius.* It shows wide reading and clear thinking, if it possesses no striking originality.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

Biological Terminology.

Actually we are now talking about biological method. In his last letter (Nature, July 28, p. 680) Sir Archdall Reid makes three appeals to me. My own contribution to the discussion has been confined to a defence of systematic biology, and I have no authority to answer for any "sect of biologists." But surely most of us accept the principles of scientific work that he lays down; most of us realise that our interpretations are mere working hypotheses; and most of us are always on the look-out by observation or experiment for those crucial facts which shall confirm or upset our hypotheses. My own difficulty has been either to devise a question that should be universally accepted as crucial, or, having devised one, to elicit the relevant facts. Biologists who can experiment with their material are certainly in a better position to perform both these operations than is one who can only observe portions of extinct animals. The distinguished author whom Sir Archdall Reid quotes merely uses a little more force in making essentially the same remark. But he can defend himself—if he cares to.

If, then, there are "sects" among biologists, I should be inclined to ask: Which of them does not employ—or, rather, attempt to employ—crucial testing? Apparently Sir Archdall Reid does not study the periodicals with which I am familiar; but possibly, as a medical man, he reads *Parasitology*. I, too, happened to look at its last number, and I observed an inquiry by Mr. P. A. Buxton into the specific distinctness of the mites responsible for three forms of mange. A form known as Norwegian crusted scabies has been the subject of divergent views, and "it is," says Mr. Buxton, "much to be desired that someone who is fortunate enough to see a case should infect a few volunteers in order to discover whether ordinary itch or the crusted variety is induced, and whether, after one or two generations, the mites can in any way be distinguished from typical *S. scabiei* var. *hominis*." This is an application of the crucial test; but Sir Archdall Reid may retort that it is only another of the lakes in an Africa of malpractice, and since I cannot swamp your pages with all the other lakes I must leave him to wander in the desert.

Sir Archdall Reid offers to help me on the question of recapitulation; but I would ask him first to explain his "glaring truism." He writes, "Variation is the sole cause of non-inheritance, etc." Surely "variation" in this sense is but another name for "non-inheritance," and the rest of his sentence therefore merely states that the offspring resembles the parent when it does not differ from it. But if there is any other meaning in the sentence, then I would remind him that whether "like exactly begets like when parent and offspring develop under like conditions" is just one of the questions that divide biologists. A germinal change would be a change of the conditions, and is therefore excluded. Either "the glaring truism" is an identical proposition, or it is a statement actually disputed. In neither case is it the same as the statement that, "apart from variations, offspring tend to recapitulate the development of their parents." If Sir Archdall Reid thinks that it really is the same, he is scarcely the man to dispel our difficulties. Those difficulties are not implicit in either of his "truisms." F. A. Bather.

August 14.

The Fauna of Scottish Lochs.

In Mr. B. B. Woodward's interesting letter on the occurrence of *Pisidium Clessini* in Loch Ness (Nature, August 4, p. 715) he does not mention the depth at which his specimens were found. Loch Ness, in the deeper parts of which Pisidium has been dredged on more than one occasion, is a very deep lake in which different zones of life undoubtedly occur. In Lake Biwa, in Japan, the Palæarctic *P. casertanum* is found only at considerable depths (17–30 fathoms), and it is probable that in Scotland *P. Clessini* lives still deeper.

Last month (July) I spent investigating the fauna, and especially the molluscs and sponges, of two comparatively shallow lakes in Perthshire, Loch Lubnaig and Loch Vennachar. No evidence was obtained in either lake of the occurrence of a deep-water fauna or of the existence of molluscs at greater depths than 70 ft., at which a Pisidium (probably not *P. Clessini*) was fairly common; but the area below 100 ft. is there very small. The only other molluscs common in the two lakes were *Limnaea peregra* and "*Ancylus fluviatilis*," both of which also occur in the streams that flow out of them. The facies and habits of the Limnæa in the two lakes are different. I hope to discuss the reasons why elsewhere.

Thirteen years ago I directed attention to our ignorance of the fresh-water sponges of Scotland. Since then nothing further has been published, though Mrs. Scharff (Miss Jane Stephens) has given us an admirable account of the Irish species. In Loch Lubnaig the abnormally low water of last month afforded unusual opportunities for the study of these interesting organisms. Three species (*Spongilla lacustris*, auct., *S. fragilis*, Leidy, and *Heteromeyenia Ryderi*, Potts) were found, mostly in the form of small, thin films on the lower surface of stones that would have been almost inaccessible in ordinary circumstances.

I may also mention another interesting observation made at Loch Vennachar, namely, that a Tubificid worm common at the edge of the lake has the habit of encysting in the earth when the water retreats. Each cyst contains from one to twelve individuals closely coiled and in a state of apparent torpor. When the cysts are placed in water the wall bursts and the worms emerge in a lively condition.

Isle of Ulva, Argyllshire.

Magnetic Double Refraction in Smokes.

The letter from Prof. Elihu Thomson on "A Novel Magneto-optical Effect" which appeared in Nature of June 23, p. 520, suggested to me that the phenomena were associated with magnetic double refraction.

I used a Nernst lamp with a vertical wire; a parallel beam of light, polarised through a Nicol with the principal section at 45°, passed along a diameter close to the superior plane of a circular plate coil disposed horizontally; and, finally, a second Nicol crossed with the first.

At the bottom of the coil was arranged in a convenient way an arc lamp with metallic electrodes, able to give large quantities of smoke when carrying 30 amperes and 140 volts. A copper pipe, coaxial on the top with the coil, conveyed the fumes on the side of the magnetic field crossed by the polarised light, and was disposed so as to prevent disturbing light from the arc in the observation space. The coil

had an internal diameter of 16 cm., an external diameter of 28 cm., and a height of 6 cm., and it was possible to obtain a magnetic field of many tens of gauss.

Rising from the copper pipe, the yellowish smokes (obtained with iron electrodes by condensation of iron vapour) showed a thick layer of fumes where traversed by polarised light. In these conditions, putting on the magnetic field, light appears through the crossed Nicols and remains until the field is cut off.

In preliminary experiments I was able to determine the following characters of the observed phenomena:—

(1) Turning conveniently the analysing Nicol, chromatic polarisation is obtained.

(2) With monochromatic light it is not possible to reach extinction by turning the analyser. Using a Babinet compensator, a suitable displacement of fringes, with field excited, was observed, and appeared as positive birefringence.

(3) With light polarised in a parallel or normal plane to the direction of the field the phenomenon is not manifest.

Moreover, if the coil is arranged in a vertical position the phenomena appear if the axis of the coil is normal to the polarised luminous beam, but not if the same axis is parallel to it.

Tests made with copper electrodes gave quite negative results with the above-described arrangement. This may be explained by the weakness of the field, as by employing a powerful electromagnet the effect appears also with smoke from copper electrodes.

The Exploitation of Irish Peat.

Prof. Ryan in his article under the above title in Nature of August 4 (p. 728) states that the labour difficulty is a serious obstacle in so far that the work is seasonal. I should like to suggest that this can be overcome by adopting the method employed for the production of moss-litter (used for bedding for animals) as now practised in Scotland and elsewhere. This method allows the men employed to be engaged in cutting peat in the earlier part of the winter and whenever the weather does not permit other operations. It follows that a great quantity of the wet peat lies throughout the winter exposed to the weather, and by the alternate freezing and thawing which it experiences the texture is very much opened up. Consequent on this, when the peat is built up in the spring it dries very much more quickly than material newly cut.

It is true that this method is not practised by crofters and others who depend on peat for fuel for domestic consumption, because the resulting product is not the hard, dense, compact body which is most suitable for burning in an open fire. However, for the exploitation of peat on a large scale this should not be necessary, since the peat is bound to be burned in closed furnaces with a strong draught. So far as my experience goes, it leads to the conclusion that the texture only, and not the composition, is altered by exposure during winter.

The adoption of this method would solve one of the most important labour problems, namely, the constant employment of the necessary able-bodied men. It would not permit the employment of women throughout the whole year, but would require their services to be dispensed with for about three months during the worst part of the winter. Whether such an industry could furnish an adequate wage for the workers in it is a question that can be considered only with reference to the specific conditions of surrounding industries and consumers.

Alexander Fleck.

26 Manor House Road, Jesmond, Newcastle-upon-Tyne, August 8.

Scarcity of Swallows.

The following may not throw light upon the scarcity of swallows in England this year, as noted in Nature of July 14, p. 628, but will explain a shortage in another part of the world, and may be of interest and suggestive.

I live in the Gran Chaco of Paraguay, South America. In July, 1920, there was a succession of dull days extending over a week, accompanied by fine rain and a temperature varying between 20° and 10° C., strong winds also prevailing. On the fourth day of these conditions the swallows sought refuge in the buildings of the Mission Station, where I reside, and for three days dead bodies of the birds were picked up, and afterwards no more birds were seen. A few days later I had to make a journey which took me in a direct line for 120 miles, during which I did not see a single swallow. Managers of four cattle farms through which I passed reported a mortality of swallows at their establishments similar to that seen at the Mission Station. From other reports I concluded that the whole area of the Gran Chaco had been affected by the bad weather, and as in the month of July swallows are always more numerous than in other months and pass in flocks northward, I fear the mortality to swallows in South America must have been very great. The deaths were the result of the lack of insects rather than of the cold.

Earthworms Drowned in Puddles.

Anglers use earthworms, and worms found in the little heaps of mud-scrapings on country roads are specially valued as being of a fine, delicate pink colour, clean and tough. I have heard anglers in North Wales say that no worms were so good, especially for sea-trout. But since road-tarring became so general the phenols (=carbolic acid) dissolved out of the tar by rain destroy the worms. Unfortunately, in numberless cases the trout have also been destroyed, adult fish as well as fry, and American experiments have proved that the spermatozoa of fish are killed by carbolic acid from tar even when so diluted as to be almost undetectable by any test.

R. B. Marston.

19 Adam Street, Strand, August 7.

The Neglect of Science.

A lady called on me to-day saying she had been sent by the sanitary inspector of a large town a few miles from Manchester with specimens of a little winged beetle (*Niptus hololeucus*), which she and the inspector thought might be bed-bugs.

Is it not extraordinary that those who are placed in posts of great responsibility in sanitary matters are so ignorant of their job that they cannot distinguish a flat wingless bug from a harmless and almost spherical beetle?

I wonder how much money has been wasted in unnecessary fumigation and the destruction of bedding by the crass ignorance displayed by sanitary inspectors of the elements of the natural history of their calling.

The Determination of Sex.

By PROF. R. GOLDSCHMIDT, Kaiser Wilhelm-Institut für Biologie, Berlin-Dahlem.

In this communication it is proposed to give an exposition of the subject of the determination of sex presenting chiefly the line of argument which the writer has been able to develop from recent work on the question. In doing so it will be convenient to confine our attention to one line of thought, though this will compel us to omit mention of much important work upon the problem. Further, it is proposed to limit the account to the writer's own field of work—namely, the animal kingdom. For a more complete account we refer the reader to the author's book, "Mechanismus und Physiologie der Geschlechtsbestimmung" (Borntraeger, Berlin, 1920).

The situation in regard to sex which is typical in nature is that out of a number of fertilised eggs of a given species about equal numbers of male and female individuals are developed. The problem of the determination of sex, then, presents itself in the form of two principal questions: first, what is the mechanism which, at a certain moment, separates the flow of development into two different streams—those of female and male differentiation; and secondly, what is the material difference in the two sets of individuals thus separated, and how does the supposed difference act physiologically in order to direct individual development along female or male lines? We may call the first of these questions the problem of the mechanism of distribution of the two sexes; while the second is the problem of the physiology of sexual determination.

It will be clear to every student of biology that the first problem in question is part of the general problem of the mechanism of heredity—*i.e.* it is concerned with the transmission of genetic properties from parent to offspring and their distribution among offspring. Therefore the study of the mechanism of distribution of the sexes has formed an integral part of modern work in genetics, and partaken of its triumphal progress. We may safely say that to-day, in the light of Mendelism and the work accomplished in the realms of cytology, the problem is solved as completely as the methods of biology permit.

The first successful attack upon the problem was made when Doncaster and Raynor discovered and studied the famous case of sex-linked inheritance in the currant-moth, and Bateson and Punnett furnished the Mendelian analysis of the case. By following the hereditary distribution of a somatic character closely linked with the distribution of sex, the inference could be drawn that one sex must be heterozygous for a Mendelian factor connected with sexual differentiation, and the other sex homozygous. Thus one sex produces two kinds of gametes in respect to the factor in question, the other sex only one kind. The resulting situation is, therefore, the same as in a back-cross between a hybrid A*a* and the pure recessive form *aa*; both types reappear again in the offspring in equal numbers. Since then an immense number of cases of sex-linked inheritance have been analysed, all with the same general result; one sex is homozygous in regard to a sex-differentiator, and produces one type of gametes—*i.e.* it is homogametic; the other sex is heterozygous, and produces two types of gametes—*i.e.* it is heterogametic. There is one complication so far as certain groups of animals are concerned: in mammals and in most of the insects the male is the heterozygous sex, whereas in moths and birds it is the female which produces the two kinds of gametes. The possible meaning of these two types is, however, a question of detail which does not concern us here.

Almost simultaneously with the solution of the problem of the mechanism of distribution of sex in terms of Mendelian symbolism, McClung announced that the odd chromosome found in the sperm-cells of certain Orthoptera and Hemiptera might act as a differentiator of sex. Since then the study of the sex-chromosomes has progressed with a rapidity and success which have rivalled Mendelian discoveries regarding sex. The simple result which stands out to-day as one of the basic facts of cytology is this: all the cells of the body of many animals contain in one sex either an odd chromosome, called an X-chromosome, or an unequal pair of chromosomes, called an X–Y group. The cells of the other sex contain, instead, two X-chromosomes. As is well known, all sex-cells undergo a reduction division which reduces the somatic number of chromosomes to one-half; this reduction is brought about by a pairing of each maternal with a corresponding paternal chromosome and subsequent disjunction of whole chromosomes during the meiotic division. An odd X-chromosome, whether it has a Y-partner or not, must, therefore, pass undivided to one of the daughter-cells during the meiotic division. The result is the production of two mature sex-cells, one with X, the other without X. In other words, the sex containing the odd X (or the X–Y group) forms two kinds of gametes, which are with and without X respectively—*i.e.* it is heterogametic. The other sex, however, with its two X's, produces only gametes with X, and is therefore homogametic. In fertilisation, then, an X-gamete of the latter sex may unite either with a Y-gamete, or with an X-gamete of the heterogametic sex. The result is XX- and XY-zygotes—*i.e.* the two sexes.

The close parallelism between the genetic and cytological facts led Gulick, Morgan, and the writer to venture the opinion that the genetic facts of sex-linked inheritance could be completely explained, if it were assumed that Mendelian factors which are inherited in that peculiar way are carried within the X-chromosomes. Such an assumption would lead to the view that the Mendelian explanation of sex-linked inheritance and

distribution of sex is only a symbolical way of representing what actually happens when the mechanism of the X-chromosomes is set to work; or, as we put it occasionally, both sets of facts express the same thing in different language.

Recent work has proved the correctness of such assumptions. We need mention only that in the fly Drosophila, where breeding work showed the male to be the heterozygous sex, cytological investigation also demonstrated the existence of an X–Y group in the male (Morgan and collaborators); in moths, where genetic proof exists that the female is the heterozygous sex, the existence of an odd X-chromosome in the female was conclusively shown (Seiler). But what we may regard as final proof was furnished by Bridges when he analysed cases in which unexpected genetical behaviour of sex-linked characters was shown to be explicable on the assumption of a non-disjunction of sex-chromosomes during the meiotic division, and when he was able to add cytological evidence of such an event to the genetic proofs. Thus we are led to believe that the mechanism of the distribution of the two sexes among the offspring is perfectly known; it is furnished by the distribution during meiotic division of the sex-chromosomes, carrying, among other factors, the sex-differentiators. We are confident that the little opposition which is still encountered occasionally will soon vanish before the weight of facts in favour of such conclusions.

A knowledge of the mechanism at work is a safe basis from which we may attack the second part of the problem of sex and so find an answer to the question: How does the one-X–two-X mechanism act physiologically in order to secure the differentiation of one or the other sex? The first attack upon this problem has been made by analysing a phenomenon which we have termed "intersexuality," and the main line of the facts and the analysis in question are given below.

The work was done with the gipsy-moth, in which the female is the heterogametic sex and the mechanism of the distribution of sex is perfectly normal. The phenomenon of intersexuality occurs, then, as breeding experiments show, without any disturbance of this mechanism. Intersexes—*i.e.* individuals which show definite mixtures of the characters of both sexes, and, as a whole, appear to occupy a definite position between the two sexes—are produced regularly and at will in crosses between different geographic races of the gipsy-moth. If, for example, a female of the Japanese race from Tokyo is crossed with a South European male, all the offspring are normal; in the reciprocal cross, however, all males are normal, but all would-be females intersexual. Or, again, if we cross a female of a Japanese race from Hokkaido with a male from Fukuoka, all the offspring are normal, but in the reciprocal cross all females are normal and all would-be males intersexual.

If we fix our attention, for the sake of simplicity, only on the intersexual females—*i.e.* intersexes with the factorial and chromosomal constitution of a female—we may state that the majority of the different races belong to one of two categories—first, what may conveniently be termed weak races; and secondly, strong races, which are those the males of which, if crossed with the female of a weak race, produce normal males and intersexual females. In testing the different strong races at our disposal in crosses with females of any particular weak race, we find among the strong races a graded series according to "strength." The males of one strong race produce with the weak female a low type of intersexuality, individuals which exhibit only slight addition of maleness to their female constitution. Another strong race produces with the same race of females a higher type of intersexuality; still another may produce a high grade of intersexual females; while a fourth may finally transform all would-be females into males, which cannot be distinguished (except by breeding tests) from genetic males. If we test the different weak races by crossing their females with any particular race of strong males, we find again a series of degrees of weakness as shown by the lower or higher type of resulting intersexuality. From such experiments it follows that female intersexuality is produced if a female of a weak race is crossed with a male of a strong race; further, that the grade of intersexuality depends upon two variables—viz. the relative degrees of weakness and strength of the parental races; in other words, it depends upon a quantitative relation of what we have termed weakness and strength.

By applying breeding tests it was shown further that strength follows in inheritance the distribution of the X-chromosomes or the sex-factor. Strength must therefore be regarded as a property of the well-known Mendelian sex-factor located in the X-chromosome. What we have termed weakness, however, is inherited purely maternally. This may mean that it is transmitted within the protoplasm or the Y-chromosome, and in any event it must be equally present in every egg. All these facts show clearly that an explanation on ordinary Mendelian lines is not possible. Something has to be added to ordinary Mendelian symbolism in order to account for the facts, and this addition is the assumption that the factors in question are possessed of a definite valency which acts in a quantitative way.

The X-chromosome contains the factor for maleness, whereas the factor for femaleness is inherited maternally. The quantity of the latter is constant for each egg, whereas the quantity of the former is double in the male (XX), single in the female (X). If there exists such a normal relation that the one male quantity is less efficient than the female quantity, while two male quantities act more strongly than the constant female quantity, and, further, if it be assumed that the higher quantity controls sexual differentiation, it is obvious why normally one or the other sex is produced, although each egg might,

as experiments show, develop into a female, a male, or something between. Finally, if it be assumed that the strong races are possessed of sex-factors of a higher absolute quantity, the production of intersexuality in the crosses is also explained—the big dose of a male factor confronted as the result of crossing with a dose of the female factor which is relatively too small determines the character of the offspring even in the one-dose (X) state. As a matter of fact, all the breeding experiments devised to test such views have given results in accordance with theory.

Fortunately, the analysis of the intersexual individuals could be pushed one step further towards a physiological understanding. It could be demonstrated by a very large number of really amazing morphological and embryological facts that intersexual females are individuals which had developed up to a certain moment as females, when suddenly the sex had changed and development was finished as a male. Similarly, intersexual males begin as males and end as females, and the different types of intersexuality were proved to be the consequence of the position of the turning point in development. A late turning point means that only certain organs, which have not completed their development, can be forced into the line of differentiation of the other sex; the result is an intersex of low grade. An earlier position of the turning point consequently leads to the production of the higher grades of intersexes, and a still earlier position to the complete reversal of sex. The degree of intersexuality is inversely proportional to the position of the turning point in the progress of development. The position at this point of the analysis is this: on one hand we have the presence of characteristic doses of substances called sex-factors in definite quantities; on the other, there is a period of varying duration (the time of development up to the turning point), the length of which is proportional to the difference in the quantities of the two sex-factors. This points emphatically to the idea that the sex-factors are substances which cause, take part in, or accelerate a reaction in proportion to the quantity present. The result may then be represented in the graph (Fig. 1): on the abscissa is plotted the time of development, the line *t*–*t* being the end of embryonal and larval differentiation. The ordinate indicates the amount of that product of the activity of the sex-factors which carries differentiation in the direction of one sex. The curve F shows the rate of production of the female-determining substances, which is constant for each egg of a given race. M*m* is the curve for the male-determining substances in the female (one dose, X); MM in the male (two doses, XX). In normal reproduction the F and M curves do not intersect in development. M_1m, M_2m, etc., are the curves of the male-determining substances produced by the larger quantities of M substance in the X-chromosomes of the strong races. Their points of intersection with the F curve (in the case of hybrid combination) occur during development, and represent the turning point where sex changes from femaleness to maleness. The graph then gives the physiological solution of the case of intersexuality; simultaneously it answers the question which led to the consideration of the work on intersexuality—viz.: How does the presence of one or two X-chromosomes containing sex-factors act physiologically in order to induce the differentiation of one or the other sex? The answer is: The mechanism which produces germs with two and one X respectively is an ideal mechanism to secure the higher velocity to one or the other of two simultaneous and competing reactions, namely, the male and female reaction, by starting it with the greater quantity of reacting substance.

But there is a limit to our analysis so far as the work on intersexuality is concerned. We can see no means of ascertaining in moths in what this reaction, the velocity of which is influenced by the concentration of the reacting substances, really consists. The answer can be given, we believe, by the facts of hormonic intersexuality.

It is well known to every student of biology and physiology that in the higher vertebrates, at least in birds and mammals, the endocrine function of the sex-gland plays an important *rôle* in the development of secondary sex-characters.

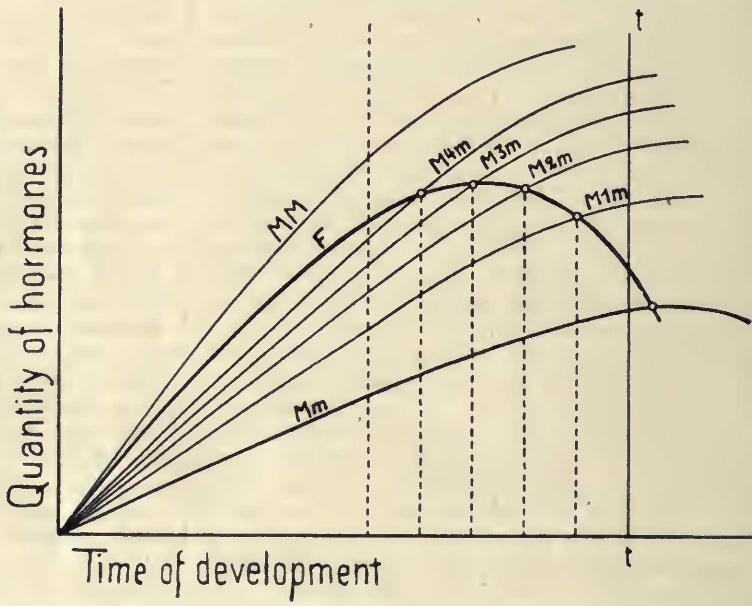

FIG. 1.

Early castration in mammals prevents the normal development of the visible characters, and results in the assumption even of female secondary characters by male birds. Early and successful transplantation of the heterologous gonad makes either sex assume, to a more or less complete degree, the characters of the other sex (Steinach, Goodale, etc.). We might term this the production of hormonic intersexuality, but, of course, changes appear only in those organs which are able physiologically to change under the influence of hormones, irrespective of the genetic constitution in regard to sex. But the methods which have to be used exclude a complete experiment in intersexuality, where the entire body, including sex-glands, ducts, etc., must react. Fortunately, Nature has performed such an experiment for us, as the recent analysis of the case of the "free-martin," which we owe to the work of Keller, Tandler, and Lillie, has revealed. Among twin calves, cases of normal male and female are very rare. If both are not of the same sex, in most cases a normal male is accompanied by an abnormal hermaphrodite female, the freemartin. It is now known that this freemartin is a typical case of hormonic intersexuality. The authors quoted above have been able to show independently that in this case—but in this case alone—an anastomosis between the blood-vessels of the twins occurs, so that the same blood flows through both. In the male partner the testis, with its interstitial tissue, develops first, and before the ovary of the female has reached the stage of endocrine function. So the female comes under the influence of the male hormones, the ovary stops differentiation, and all the sex-characters develop in the male direction. The result is the freemartin, a calf with female external sex-organs, almost male sexual ducts, and a sex-gland containing sperm tubules which are incapable of spermatogenesis. Most interesting corroboration of this interpretation has recently been furnished in Lillie's laboratory by Minoura, who was able to produce hormonic intersexuality experimentally by transplanting gonads into developing chickens' eggs.

If we compare this case of true hormonic intersexuality with the zygotic intersexuality of the moths, we see at once that the "turning point" from which sexual differentiation changes in the intersexual moth corresponds exactly to the moment when the male hormones are poured into the blood of the female in the case of the freemartin. Comparing the facts carefully, we feel justified, therefore, in giving the following answer to our former question: What is this reaction which is accelerated by the action of the sex-substances with a velocity proportional to their concentration? The reaction is the production of the specific hormones of sexual differentiation. In insects this occurs in every cell of the body as an irreversible consequence of the combination in fertilisation. In the higher vertebrates the reaction becomes more or less centralised within the interstitial tissue of the sex-glands.

That this solution of the problem of sex comes near the truth is rendered probable by the ease with which even the most complicated sexual phenomena fall in line with the theory. The questions of parthenogenesis and sex, sex-mosaics or gynandromorphs, sexual polymorphism, inheritance of secondary sex-characters, and the different types of hermaphroditism, all find simple solutions, or, at least, appear capable of such. This may be demonstrated in the interesting case of the Gephyrean worm Bonellia, well known for its extreme sexual dimorphism, the male being a rudimentary microscopic worm which lives as a parasite in the oviduct of the large female. Baltzer made the discovery that part of the larvæ, developed from fertilised eggs, become attached to the proboscis of an adult female, and live there for some time in a semi-parasitic way before developing into males. Larvæ, however, which undergo development without the parasitic stage remain for some time undifferentiated, and then develop into females. If larvæ which are fixed to the proboscis of a female are removed after a shorter or longer period, intersexes of different type are produced. Let us now suppose that we could devise an experiment to prove directly the correctness of the quantitative view of sex-determination as represented in the above graph. We might perform it successfully by finding a method of accelerating or retarding the rate of differentiation without influencing the rate of the production of the sex-hormones. In the event of success we ought to be able to shift the point of intersection of the F and M curves back into the time when differentiation was still in progress. The result would be intersexuality. It seems that Bonellia is able to perform this experiment by means of the excretion of her proboscis. The F and M curves of the larvæ seem to have such a relation that the male hormones are being produced quickly, and the female hormones slowly. The normal rate of differentiation is slow—so slow that sexual differentiation begins only when the phase of action of the male hormones has passed, and females are produced exclusively. The secretion of the proboscis, however, accelerates the rate of differentiation in a way analogous to the action of the thyroid in accelerating metamorphosis in amphibians. In the case of parasitism of the larvæ, therefore, differentiation takes place during the phase of action of the male hormones. Interruption of the influence of the secretion naturally causes intersexuality. Finally, we may state that recently we were successful to a certain extent in imitating this experiment with moths. By employing low temperatures we could put back the turning point for females of pure races of the gipsy-moth and thus produce intersexuality.

Ever since genetics assumed its modern form the problem of sex has been closely linked with the general problem of heredity. The Mendelian study of sex formed part of the general study of

genetic factors, while the cytological study of sex was closely connected with the chromosome-theory of Mendelian heredity. It therefore appears rather tempting to apply the quantitative views of sexual differentiation to the theory of heredity in general. Recently an attempt has been made by the writer in "Die quantitativen Grundlagen von Vererbung und Artbildung" (Berlin, J. Springer, 1920) to attack the problem of the physiology of heredity from this point of view. A discussion of this would, however, be beyond the scope of this contribution.

Further Remarks on Relativity.[1]

By Sir Oliver Lodge, F.R.S.

III.

Changes of Frequency.

According to the usual presentation of relativity, clocks appear to go slow to a relatively moving observer; quite irrespective of any Doppler effect, which can readily be allowed for. Their rate would have to be multiplied by the fraction $1/\beta$ or $\sqrt{(1-u^2/c^2)}$; which means that a clock on the sun seen from the earth, say on December 31 or July 1 when the motion is exactly transverse, would lose one second in two hundred million, or about sixteen seconds per century.

But, for testing purposes, we cannot change the motion appreciably, and so we cannot hope to tell if the clock would seem to go quicker if we stopped. Reversal of motion, even if it could be accomplished, would be no good; the difference to be observed—unlike the Doppler effect—is between motion and rest, or between rapid motion and slow, not between *plus* and *minus* motion. If we had a clock which we could fix at relative rest to ourselves, and yet be sure that it kept time with the one we were observing on some relatively moving body, the comparison might be made. And the revolution or vibration of a radiating atom, (*a*) on earth, and (*b*) on sun or star, appears to satisfy the conditions. If source and observer were moving together, there would be compensation; but if either was moving without the other, there should be an effect, such as by long accumulation might be detected. The Mercury effect allowed accumulation for a century or more. The spectrum effect does not allow any accumulation; whatever can be seen there must be seen instantly, it must depend on what happens in a single period. It is true that a certain train of waves is needed for visibility, and some succession is necessary for interference; but so short is the series required for interference that position in the spectrum is practically dependent on individual wave-length.

The value of u^2 for the earth's orbit, considered circular, is equal to the sun's gravitational potential at the earth's distance under the inverse square law, say $-V$; or twice that potential under the direct distance or centrifugal-force law. Hence the slowness to be expected, $\sqrt{(1-u^2/c^2)}$, may be written either $1+V/2c^2$ or $1+V/c^2$; and the second term is the displacement towards the red which is being looked for. Only, of course, it is being looked for where the potential is strongest, viz. close to the sun; for there it is two hundred times stronger than in the neighbourhood of the earth (the radius of the earth's orbit being two hundred times the radius of the sun). It seems, however, that a small fraction of the gravitational effect ought to be produced as the result of the earth's motion, even if the sun were nothing but a central source of light.

The occurrence of the factor 2 is curious, and corresponds with a similar factor in the ray-bending calculation. But I do not now discuss it, because a spectral shift due to transverse motion is doubtful. Space-measuring rods shrink, it is true, but in the direction of motion, not in the sun's direction; so the measured velocity of light from the sun would be constant without any time-correction. Yet it is not easy to see how a clock-discrepancy can be dependent on the direction of motion, apart from the ordinary allowance for light-speed.

Changes of Inertia and Weight.

That an electric charge possesses the fundamental material quality of inertia, by reason of the magnetic field which inevitably is generated when it moves, was first calculated by Sir J. J. Thomson so long ago as 1881. That this electrical inertia is a function of speed, so that as the speed of light is approached it ought to undergo a rapid increase of value, was predicted, and its amount reckoned, by both J. J. Thomson and Oliver Heaviside. That the facts of observation were in accord with the prediction, was verified, first by Kaufmann and then by others; while that this subordinate dependence of inertia on speed applies even to neutral atoms of matter, is a consequence of the fairly ascertained electrical nature of their constitution. On the theory of relativity the variation of inertia appears to follow, without any electrical theory at all, as a result of changing the frame of reference to moving axes. The additional mass corresponds to the kinetic energy of the moving matter divided by c^2. Which suggests that the whole mass is probably a demonstration and a result of fine-grained ætherial rotational energy with velocity c.

It is legitimate, anyhow, to assume as a working hypothesis that the mass of a body is not really constant, but that at the speed u it becomes $m=\beta m_0$ or $m_0/\sqrt{(1-u^2/c^2)}$.

The speed necessary to display this effect is usually attained only by electrons and positive nuclei in a vacuum tube, or by aid of spontaneous radio-activity; but the refinements of astronomy are so great that the planet Mercury is moving fast enough to exhibit some result dependent on

[1] Continued from p. 751.

this variation of inertia, if it were allowed to accumulate for a century. If the speed were constant it could not be detected; but the speed is not constant. The orbit is elliptical, for one thing; and the solar system is in motion, for another. Sometimes, therefore, the solar drift will be added to the orbital speed of Mercury. sometimes it will be subtracted from it.

Here then is a definite problem: to trace the consequences of this variation of inertia on the form or details of its orbit; and this problem I attacked in the *Philosophical Magazine* for August, 1917, and found that it must lead to a cumulative apsidal revolution unless there were some compensating cause. The paper was followed up by Prof. Eddington in September and October 1917 and June 1918, by Mr. G. W. Walker in April 1918, and by myself again in December 1917 and February 1918.

We found that if the solar drift were sufficient, both in magnitude and in direction, to give the proper value for the perihelion progress of both Mercury and Mars—as it easily might be—a smaller effect could not be denied to some of the other inner planets; and there would be accompanying small eccentricity changes, not corresponding with observation. The best solar drift is one with the speed $1 \cdot 7 \times 10^{-4}\, c$, and longitude 173°, for its component in plane of ecliptic. This will suit Mercury, both for apsidal revolution and for eccentricity. The perturbations that ought theoretically thus to be caused in the other inner planets are tabulated below; and, to compare with these calculated values, the table gives also the actual estimated or observed outstanding secular variations per century, both for the perihelion progress, $d\varpi$, and for the change of eccentricity, de. (See *Phil. Mag.*, February, 1918, pp. 148 and 154.)

Outstanding Perturbations per Century.

Solar drift assumed: *Speed*, 1·7 × earth's orbital vel. *Direction*, 173° long. and 0° lat.	Calculated.		Observed.	
	$ed\varpi$	de	$ed\varpi$	de
	″	″	″	″
Mercury	+8·34	−0·91	+8·48	−0·88
Venus	+1·46	+1·52	−0·05	+0·21
Earth	+1·04	+0·32	+0·10	+0·02
Mars	−0·12	−0·46	+0·75	+0·29

The discrepancies between theory and practical estimate, though small, are considered to be beyond anything that can reasonably be attributed to errors of modern observation; and if that is the final verdict of astronomers, after reconsideration of the figures, it becomes a question what is the compensating cause that prevents fluctuations of inertia from taking effect. The only cause that has suggested itself is a variation in the Newtonian gravitation constant, due to its being a function of velocity; so that weight is modified, somewhat in the same sort of way as electrostatic forces are modified, by rapid motion. (*Phil. Mag.*, February, 1918, p. 156.)

Prof. Eddington has now agreed (see his admirable book, "Space, Time, and Gravitation," p. 125) that the result of the whole discussion is to prove that gravitation has "joined the conspiracy," and has succeeded in concealing any effect of uniform motion.

But, on Eddington's improved theory (*Phil. Mag.*, October, 1917), it achieves this result in an odd way, and apparently does not sustain Einstein's "Equivalence" thesis, that inertial mass and gravitational mass are the same in all circumstances; or, briefly, that weight is always proportional to mass. Some caution is here required; for the proportionality of weight and inertia seems to be interfered with at high speeds. Their product, not their ratio, appears to be involved in a planetary perturbation, regarded from the point of view of the electrical theory of matter; and hence, if one increases, the other must decrease.

Galileo's experiment on the Tower of Pisa, roughly, and Newton's pendulum determinations, more exactly, established the proportionality of mass and weight; and recently Prof. Eötvös, followed by Prof. Zeeman, has confirmed Newton's conclusion to a high degree of accuracy, so far as ordinary circumstances and slow motions are concerned. (See the excellent new edition of Clerk Maxwell's wonderful little book, "Matter and Motion," brought out last year by Sir Joseph Larmor (S.P.C.K.), pp. 34 and 143.) But the astronomical evidence cited above seems to require that the Newtonian gravitational constant shall diminish at high speeds, being multiplied by the factor $1 - u^2/c^2$. Only thus can it compensate the inevitable increase of inertia $(1 - u^2/c^2)^{-\frac{1}{2}}$; at least if the increase of inertia sustains its full increment of weight. If the increase of inertia due to motion is *not* subject to gravity, then $\sqrt{(1 - u^2/c^2)}$ will suffice as the factor of the gravitation constant. (*Phil. Mag.*, February, 1918, pp. 143, 145, 155.)

Assuming that so it will turn out, after further detailed scrutiny, it is clear that weight is affecteo by high-speed locomotion. For the increased mass of a fast-revolving planet would by itself undoubtedly cause a minute apsidal progression sufficient to be observed; and the fact that for several of the inner planets the outstanding perturbations are less than the calculated, shows that compensation must somehow occur. It is to be hoped that the peculiar nature of the compensation, here suggested. may ultimately throw light on the gravitational structure of the æther. Meanwhile, unless some error is detected, it appears in conflict with the universal proportionality of mass and weight.

We shall now proceed to a few remarks on points connected with the more general theory of relativity.

Erratum.—In the first article of the present series (Nature, August 4), on p. 718, 1st col., l. 6 of 2nd para., *delete* the words "in v if it is opposed to u"; and *substitute* "when the observer reverses his motion."

(*To be continued.*)

Cohesion.

By DR. HERBERT CHATLEY.

WHEN one turns from an account of the discovery of a "dark star" by celestial dynamics to an investigation of the properties of the excessively minute whirling electrons in an atom, the impression is gained that within these limits at least there is but little more than relatively unimportant detail to learn. Such a notion is quite erroneous. More is known of the mechanism of plants on one hand and of electrons on the other than of the most ordinary and apparently simple mechanical phenomena. The most expert physicist can make only a near guess as to the motion of a billiard ball under given conditions as to stroke, weight, etc., since there is an imperfectly known factor, friction, in the problem. Similarly, although he can calculate with great precision the force with which one piece of iron attracts another when they are a foot apart, he cannot say with any accuracy from first principles what is the tensile strength in each piece of iron. Engineers similarly have made countless experiments and have also obtained very many data from constructional experience which give average values from which, by allowing a liberal margin for uncertainty, structures can be safely designed; but that is all.

Doubt still prevails as to the nature and laws of the force or forces causing cohesion. Lord Kelvin concluded that Newtonian gravitation would explain cohesion if it be supposed that the particles are exceedingly close. Sutherland and Nernst have regarded cohesion as identical with chemical affinity, and therefore with electrostatic force. Tolver Preston believed it was due to some mysterious dynamic action arising from the oscillation of the particles. Crehore, an American physicist, deduces it from a residual electromagnetic effect of the omnipotent electrons. Most recent students, following Sutherland, regard it as a residual electrostatic effect of the opposed charges in the atoms which, although in electrical equilibrium, are not coincident in space; some, however, prefer to consider it as largely electromagnetic.

The only satisfactory method of commencing a scientific investigation is to state all the known particulars and formulate hypotheses on the basis of the apparent facts. Proceeding so, we may note that:—

(1) All solids, being such, cohere to an extent which changes with their composition, physical structure, and temperature. Broadly speaking, cohesion varies with density and decreases with increase of temperature. It is quantitatively of the order of one millionth of a dyne per molecular pair.

(2) The range within which cohesion is effective is very small, not greatly exceeding one molecular diameter. Two pieces of material when pressed together cohere only when great force is used, if they are very highly polished or if they are so soft that they readily interpenetrate. Solids, with very few exceptions, break by tension when stretched 25 per cent. of their length, implying that the particles need to be separated only by less than one-and-a-quarter times the usual distance from centre to centre for cohesion to become inappreciable. Even the exceptional substances, such as rubber, break when stretched but little more than twice their length, and do not change much in volume. Solids at the fusing point become liquid with negligible change of temperature and only from 5 to 10 per cent. increase of volume.

(3) Solids in general, with the exception of the so-called plastic materials, extend with tension and shorten with compression proportionately to the force employed within certain "elastic limits," and are stable within those limits. The volumes increase slightly up to the elastic limits.

(4) Beyond the elastic limits the tensile and compressive strengths increase but slightly, and when the strain (extension or compression) becomes appreciable the strengths decrease.

(5) Liquids and gases show a slight "molecular pressure" or internal attraction, varying approximately as the inverse fourth power of the distances between the centres of the molecules.

It should perhaps be pointed out that an inconsistency is involved in the notion of "failure by compression." It is obvious that compression can do nothing but bring the particles into closer proximity, and if lateral expansion is prevented ultimate failure is inconceivable unless there are internal voids. Ordinary compression causes failure either by oblique sliding ("shear") or by lateral expansion.

It is required, then, to find a force which has no external resultant under natural conditions (save perhaps the normal gravitational attraction), resists tension and compression proportionately to the displacement of the particles for small ranges, and has but a limited power to resist tension which ceases at a moderate range and a great power of resisting compression. It is difficult to conceive of one force having all these properties, but perfectly simple to imagine an attraction and repulsion combined that will do so, provided that *the attraction decreases more slowly with separation than the repulsion.* A series of papers by the present writer to the Physical Society of London (1915–19) and a paper in the *Phil. Mag.* (August, 1920) attempt to deal with the problem on these lines. When the solid is at rest the attractions and repulsions balance. If a tensile force is applied the particles are separated, but since the attrac-

tion diminishes less rapidly with separation than the repulsion, there is a surplus of attraction which provides a tensile resistance. If the applied force is increased, the resistance will also increase up to a certain value, depending on the rates at which the attraction and repulsion respectively change. Further strain causes failure. On the other hand, if a compressive force is applied the particles are brought together and there is a surplus of repulsion which, like the surplus of attraction, varies with the amount of the strain, but differs in that it may be indefinitely great for very high proximity of the particles.

As to the rationale of the process little can be said. The dynamic energy of the oscillating particles and the consequent rigidity of the atoms and molecules seem to provide a kinetic basis for the repulsion. As is well known, most solids contract when they lose heat, and, since heat is electronic, the fact that most solids increase in cohesion when cooled would be quite consistent with atomic and molecular oscillation or rotation, provided that such motion is the cause of repulsion.

Whether the attraction is electrical, chemical, dynamic, or unique is not fully determinate, but since there is a fairly consistent hypothesis in terms of electrical theory, a bias in that direction is natural so long as no practical objections occur. Kelvin's gravitative theory seems to be baseless, for it leads to inconsistent results when the actual spacing of molecules is considered; but there is no intrinsic objection to an hypothesis which would make gravitation the residual of cohesive attraction. The writer has developed an empirical formula on these lines which gives a continuous expression for cohesion and gravitation. Newton's great discovery was that gravitation varies as the product of the masses concerned divided by the square of the distance between their centres, and the success of this law in explaining the motions of the heavenly bodies proves with overwhelming certitude its accuracy for all distances but the smallest, and possibly also the enormously great. When, however, the distance is comparable to the usual distance between the centres of the atoms or molecules in a solid a strong doubt as to the applicability of Newton's law arises, for it would appear that when two molecules are separated to twice their usual distance in a fluid the mutual attraction in the second position falls away much more rapidly than Newton's rule implies, and the attractions are quantitatively enormously greater. We may of course suppose, as did Sutherland, that gravitation has nothing to do with cohesion, but this does not satisfy the craving for continuity.

Here, then, is a field for investigation of the highest practical importance. If cohesion can be properly connected to other physical properties it is conceivable that new compounds of great strength, due to a critical state of cohesion artificially produced, would be found. Chemistry, crystallography, metallurgy, and engineering would all benefit by such an advance in knowledge of the ordinary properties of matter. Somewhat paradoxically it would appear that a complete solution of the macroscopic properties of matter would also solve the question of the inner structure of the molecules and atoms.

International Conference of Chemistry.

THE International Conference of Pure and Applied Chemistry held at Brussels at the end of June was nominally the second of these conferences, that at Rome in 1920 being the first; but there were at least two earlier assemblies in London and Paris which led up to the organisation, which seems now to be firmly established.

More than twenty countries are included in the organisation, Germany, Sweden, and Austria being the principal ones which are not yet represented. A number of well-known chemists took part in the conference:—Profs. Chavanne, Crismer, Swartz, and Timmermans (Belgium), Billmann (Denmark), Conant and Mackall (United States), Moureu, Béhal, Matignon, and Urbain (France), Pope and Lowry (England), Garelli and Nasini (Italy), Halvorsen (Norway), Holleman and Kruyt (Holland), Guye and Pictet (Switzerland), and several representatives of industrial chemistry, including M. Kestner, to whose energy and determination the organisation is so much indebted.

Each of the countries concerned has a council corresponding to the British Federal Council for Pure and Applied Chemistry, and the various national councils appoint members of the International Council and send in addition delegates to the annual conferences. So far as Great Britain is concerned, the Federal Council has invited its president, Sir William Pope, Prof. Philip, Dr. M. O. Forster, Mr. E. V. Evans, and the two honorary secretaries, Prof. H. E. Armstrong and Dr. Stephen Miall, to serve on the International Council for the next three years.

The work of the International Conference is divided among a number of commissions dealing with specific subjects or proposals of an international character. Among these the Commission on Chemical Elements will replace the former Commission on Atomic Weights. It was felt that the exact determination of atomic weights and their publication to several places of decimals has now lost a good deal of its scientific significance in view of the work of Dr. Aston and others, and that exact atomic weights are now becoming factors of analytical calculation rather than features of a chemical hypothesis. The isotopes or atomic numbers are taking the premier place, and the atomic weights—often representing merely the average of a mixture of isotopes—will be of practical rather than theoretical interest. The

commission has therefore enlarged its jurisdiction, and will publish the constants of atomic weights, isotopy, and radio-activity; moreover, instead of being composed almost exclusively of analysts of exceptional ingenuity and manipulative skill, it will include recognised experts on isotopes and atomic pedigrees.

The questions of international nomenclature, contractions, abstracts, and standards were discussed and reports adopted, but the main work on most of these topics is still to be done, and the various committees appointed to consider these matters have a huge mass of detailed investigation before them. In connection with abbreviations in chemical literature Dr. Pondal made the gratifying announcement that the Argentine Chemical Society would bear the necessary expenses.

A list of pure research chemicals manufactured in Great Britain was submitted by the Association of British Chemical Manufacturers, and a further list containing many additional products is in course of preparation. M. Marie, whose name is well known in connection with tables of constants, submitted a report on this subject.

A commission was appointed to consider international patents, and its work is not yet completed. It appears that a considerable mass of evidence is necessary before a report can be drafted, and it is hoped that those who have given consideration to this problem will communicate with the Federal Council for Pure and Applied Chemistry at the offices of the Chemical Society at Burlington House.

The question of industrial hygiene is coming into prominence, and a commission was appointed to deal with this subject. During recent months papers on industrial hygiene have been read before the Society of Chemical Industry, the Royal Society of Arts, the British Medical Association, and other societies, and the hygiene section of the International Labour Office constituted by the Treaty of Versailles has undertaken an immense task in relation to diseases of occupation. It is time the whole question was examined scientifically and carefully, but the problem is one of considerable complexity. Very few of the medical experts have accurate knowledge of the chemical and engineering factors involved, and but few of the manufacturers or employees most concerned are able to form a sound judgment from a perusal of the pamphlets written by experts maintaining with no little heat their various opinions. If the international commission can study the problem so far as it concerns industrial chemistry, it will perform a most useful and timely service.

It has been decided to hold the next conference of the International Union in France, and there is a suggestion to have the meeting at Lyons, which will be a very convenient locality for most of the countries concerned.

Obituary.

Prof. G. Lippmann, For.Mem.R.S.

FRENCH science has suffered a very great loss in the person of Prof. Gabriel Lippmann, who died at sea on July 13 while returning from Canada, where he had taken part in the mission of Marshal Fayolle. Prof. Lippmann was born in 1845 at Hollerich, in the Grand Duchy of Luxemburg, of French parents, who soon after his birth settled in Paris. He passed through the higher normal school, and devoted his life to teaching and research. He became professor of physics at the Faculty of Sciences in Paris in 1878 and director of the laboratory for physical research at the Sorbonne in 1886, and was elected a member of the Paris Academy of Sciences in the same year. Of an original and independent mind, Prof. Lippmann left his personal mark on all questions he touched. The philosophical and general side of scientific conceptions claimed his attention particularly, and he saw clearly the connecting links between differing phenomena. His work on electro-capillarity dates from the time when electricians began to see the power and flexibility of the new instrument. He saw at a glance the future of electricity. Every physicist knows his capillary electrometer and the connection he established between the constant of Laplace's formula and the potential difference: but he showed as well how mechanical work could be obtained from an electro-capillary motor. At the time he made these discoveries and stated the principle of the conservation of electricity he published other work in which he played the *rôle* of pioneer. In his note in the *Comptes rendus* of the Paris Academy of Sciences for 1875 on the properties of an electrified water surface, he earthed a mass of water by a wire ending in a Wollaston electrode, and showed that if a stick of rubbed resin was brought near, oxygen was set free at the electrode, while hydrogen remained in solution. Ostwald, in his "General Chemistry," begins his treatment of ionic theory with a description of this experiment. On the publication of Rowland's discovery Prof. Lippmann showed, in June, 1879, that the phenomena ought to be reversible and that electricity ought to have inertia. This idea of reversibility was a frequent subject of his thoughts, and he often reverts to it in his celebrated treatise on thermodynamics. Prof. Lippmann also published in 1889 some calculations on induction in resistance free circuits, which twenty years after were confirmed by the experiments of Prof. Kamerlingh Onnes. In 1891 he communicated to the Academy of Sciences the principles of the discovery with which his name is immediately associated: that is, colour photography by interference. The accurate solution of the problem of the reproduction of colour is thus obtained from the thin laminæ which had such an attraction for the mind of Newton. Prof. Lippmann was a man of few words. So long as he was unable to give to a problem a form which would lead him to a

solution satisfactory to himself, those who knew him little might believe him indifferent. He would gather himself together, and in a few words would show how far his thoughts had taken him into the fundamentals of the subject. During the last year of his life he devoted much attention to relativity, and on his last voyage from Havre to New York he spent most of his days discussing it with Prof. Michelson. The work Prof. Lippmann leaves behind him is of capital importance; but it represents only a part of the thoughts of a man of science with views acute and deep whom the search for perfection and a reserved temperament kept far from noise and strife.

Capt. W. E. Rolston.

The sudden death, on August 9, at forty-five years of age, of Capt. W. E. Rolston will be greatly regretted by many old students of the Royal College of Science, South Kensington, where he received his scientific training. Capt. Rolston was the founder and managing editor of the *Cologne Post*—the admirable daily paper published by the British Army on the Rhine—but he was well known in astronomical circles by his work with Sir Norman Lockyer, and at Cambridge. He entered the Royal College of Science as a Teacher in Training, and for about a year assisted in the demonstrations in the course of astronomical physics there, gaining also some experience in solar physics work. In 1899 Rolston took up a teaching post, but returned again to the Solar Physics Observatory at South Kensington in 1901, and remained on the staff of the observatory until he joined the Buffs in 1915. He was with Sir Norman Lockyer for twelve years before the transfer of the observatory to Cambridge in 1913, where he continued to be a member of the staff.

After some preliminary work in the general routine of the observatory, Rolston became mainly responsible for several specialised branches of the investigations in progress. One of the most important of these was an attempt to apply the principles of Stokes's Law of Radiation to the determination of the relative temperatures of stellar atmospheres. A fundamental feature of Sir Norman Lockyer's Kensington classification of stellar spectra required the recognition of different temperature levels, and to investigate this a special prismatic camera, with quartz-calcite optical train, was obtained and mounted on one of the equatorial telescopes. Pairs of stars were photographed on the same plate under conditions as nearly identical as possible, with controlled exposures designed to give equal photographic intensity for the region H_β–H_γ. By then measuring the relative intensity of the red and violet regions respectively, it was possible to arrange the various spectra in order of temperature level. These observations extended over about three years, and the results were communicated in a paper to the Royal Society in 1904 on the "Temperature Classification of Stars." In addition to taking a share in the observational routine work, both day and night, on solar and stellar spectra, Rolston repeated much of the reduction work on old observations of widened lines in sunspot spectra, and brought the summaries up to date.

From 1907 to 1912 Rolston was chiefly occupied with the reduction of orientations, and with stone circles and temples in various parts of the world, these being regarded as having originally been designed by their constructors to serve for the determination of time and season in the regulation of the economic and religious life of the early communities. The results of these researches were extremely suggestive, and were communicated by Sir Norman Lockyer to the Royal Society.

During the last two years before the transference of the observatory to Cambridge Rolston was engaged in preparing a comprehensive account of the observations of novæ from the discussion of all available material, and this was published as a separate volume entitled "Phenomena of New Stars." After transference to Cambridge he took charge of the Huggins spectroscopic equatorial, and also assisted in the reductional work on stellar spectra.

Throughout his connection with the Solar Physics Observatory Rolston took great interest in the dissemination of scientific knowledge, and was most successful as a writer and as a popular lecturer. For a number of years before the war he wrote the notes for Our Astronomical Column, and also contributed numerous articles and reviews. The experience thus obtained was turned to excellent account when in March, 1919, he founded the *Cologne Post,* the unique daily newspaper which has had such valuable influence in revealing British thought to Germany. His success showed the value of a scientific training to business management and literary balance, and the frequent articles and notes on scientific and educational subjects published in the columns of his journal commanded both attention and respect. Rolston was, indeed, a man of sterling worth and sound knowledge, and all who knew him will deplore that he has been taken from them in the prime of life.

Samuel Alfred Varley.

By the death on August 4 of Mr. S. A. Varley, at eighty-nine years of age, we have lost almost the last of those pioneers who were associated with the application of electricity. A younger brother of the late Cromwell Varley, F.R.S., and an early student and disciple of Michael Faraday, Mr. Varley was a notable inventor even comparatively early in life, when in the service of the Electric Telegraph Company. His name and fame will always be especially associated with dynamo-electric machinery, the first example of which he produced in 1866. This was a self-exciting machine with soft iron magnets. Ten years later Mr. Varley patented the original compound-wound dynamo. This afterwards became the subject of litigation, when Mr. Varley's claims

to priority were in the end completely established. The machine may be seen amongst the historical apparatus at the South Kensington Museum. His other inventions included a lightning protector for telegraph lines and cables, a polarised needle telegraph instrument, and the time-ball as now used at Greenwich Observatory and elsewhere.

Mr. Varley, following Lord Kelvin, contributed a highly useful paper, in 1858, to the Institution of Civil Engineers on the electrical qualifications requisite in long submarine telegraph cables, as well as another on the same subject to the Society of Arts. In setting forth here the true electrical qualifications for the working of a submarine cable, he showed in a very convincing way that conductor resistance was as much a factor in retardation as induction. He was the son of a famous artist, Cornelius Varley, and was one of a famous family of electricians. C. B.

It is with much regret that we have to record the death of M. JULES CARPENTIER on June 29. M. Carpentier was born in 1851, and received his education at the Ecole Polytechnique. In 1876 he entered the service of the Paris-Lyons-Marseilles railway as assistant constructional engineer, and would probably have developed his genius for machine construction in the service of the railway had not the death of Ruhmkorff directed his attention to the design of electrical apparatus. He took over Ruhmkorff's workshops, reorganised them, and commenced to manufacture standard electrical apparatus suitable for the measurement of the heavy currents necessary for the application of electricity to industry. Amperemeters, voltmeters, electrodynamometers, and other apparatus associated with the names of d'Arsonval, Marcel Deprez, and Baudot were in a large measure developed and made practical instruments by the genius of Carpentier. His activities did not end with electrical instrument-making, for his name is also associated with three-colour photography, while during the war his workshops turned out a number of periscopes for use on submarines. M. Carpentier was elected a free member of the Paris Academy of Sciences in 1907, where he represented the mechanical arts and the manufacture of instruments of precision.

THE death occurred on August 13, at the age of sixty-five years, of SIR ALFRED W. W. DALE, late vice-chancellor of the University of Liverpool. Sir Alfred was educated at King Edward's School, Birmingham, and Trinity Hall, Cambridge. For twenty years he was lecturer, bursar, and tutor of his old college, during which time he established for himself a reputation as an able administrator of university affairs, as well as a classical scholar. In 1899 he was appointed principal of University College, Liverpool, and when Victoria University was dissolved in 1903, and its separate colleges assumed university rank, he became the first vice-chancellor of Liverpool University, retaining this post until 1919, when he was succeeded by Dr. J. G. Adami.

Notes.

THE local secretaries of the British Association for the Edinburgh meeting desire to contradict the statement which appears to be current in some quarters that the hotels and boarding-houses of Edinburgh are fully booked for the period of the meeting. There is plenty of accommodation vacant in certain hotels, in boarding-houses, and in apartments; and in one of the hostels—a modern hall of residence—fifty places are still available for the accommodation of members. The Secretary for Hotels and Lodgings, the University, Edinburgh, will be glad to answer inquiries. Members who write to hotels and boarding-houses direct should enclose a stamped addressed envelope for reply.

THE outbreak of smallpox in Nottingham is at present kept within bounds by the incessant work of the medical and civic authorities. The trouble is that Nottingham has been for some years a hunting-ground of "anti" people. Still, we may be fairly sure that Nottingham will not suffer the fate of Gloucester, where 279 unvaccinated children died of smallpox in 1895–96. But there is always this difficulty, that vaccination in early childhood, though it may fail to give complete protection against smallpox some years later, may so modify the attack that the case is mistaken for chicken-pox. This mistake must be reckoned as well-nigh inevitable, now that smallpox is so rare that many doctors have never seen a case of it. The annual report (1920) of the Scottish Board of Health contains a good summary of the Glasgow epidemic last year. It is the old story: that the general neglect of vaccination in childhood is bringing about a reversion to the original habits of the disease. Smallpox naturally prefers children under ten years of age: and now it gets them. Of course we all know that vaccination is not a perfect method; we all hope for a perfect method; we all would like to get rid of the calf, to be able to use a non-living vaccine, exactly standardised; a hypodermic dose, and no scratching of the skin. Some day, surely, this perfect method will be worked out. Meanwhile we all know what would happen if it were possible to take a school of 200 small children, to vaccinate 100, to leave 100 unvaccinated, and then to expose the whole school to smallpox. Even the anti-vaccinationists know what would happen. The present writer put this view of the disease to one of them, and he answered that God would interfere in favour of the unvaccinated children: a fool's answer. Two cases of smallpox have just occurred in Huddersfield (*Times*, August 11). Let us hope that vaccination of contacts, quarantine, and other sanitary measures will prevent the spread of infection. Probably we shall

have other outbreaks of the disease this autumn and winter.

It is the intention of the Rockefeller Foundation to publish from time to time a circular of information reviewing its activities, and the first number was issued on July 25. A million francs was voted towards the endowment of La Fondation Reine Elisabeth, a new institution for medical research established in connection with a hospital in the suburbs of Brussels, while three million dollars have also been allocated to the Brussels authorities for medical education. Reference is also made to the grants of five million dollars each to Canada and to University College and Hospital in 1919 for medical education. Support has been given to several medical schools in the United States, contributions have been made towards campaigns against malaria, yellow fever, hookworm disease, and tuberculosis, and emergency relief of a million dollars has been contributed to the fund for European children. In addition, the Medical School in Peking has been maintained and aid given to thirty-one hospitals in China with the object of increasing their efficiency.

In the June issue of *Folk-lore* Mr. R. Grant Brown discusses the pre-Buddhist religion of the Burmese. It is not confined to the animistic beliefs which were possibly introduced with the so-called "corrupt" Mahayamist or northern form of Buddhism, which, to a far greater extent than the southern form which now prevails, incorporated the ancient beliefs and ceremonies of the people. The animism which now widely prevails is quite apart from Buddhism, and though Burmese Buddhism is in one sense only a veneer over the prevailing animism, it is not more superficial than the state of belief even in Western countries. It is frowned upon by the monks, yet not only do the votaries of the orthodox creed refrain from persecuting the beliefs and practices of the lower orders, but also both forms prevail even among the same individuals. A good example of this form of worship is that of the Nats, spirits of mountain, whirlpool, tree, earth or sky, rain or wind, and a hundred other things. Human sacrifice is still found in the Chindwin district, when a boy or a girl of a distant village is annually sacrificed and the blood sprinkled on the seed-rice. Cannibalism, in the sacramental form, appears in the case of a rebel leader who had been a monk and a reputed sorcerer; he was killed, his body dug up, and the flesh boiled down into a potent decoction. Mr. Brown's account of these and similar practices is interesting for comparison with customs of the same class prevalent in the lower cultures of some tribes in the Indian Peninsula.

The Pennsylvania University Museum has recently acquired a copy of a rare book, "A Catalogue of Specimens of Tapa or Bark Cloth," illustrated with samples of the cloth collected by Capt. Cook during his three voyages. The book was published in London in 1787, and contains, besides the catalogue and specimens of tapa, "A Particular Account of the Manner of Manufacturing the same in the various Islands of the South Seas: partly extracted from Mr. Anderson and Reinhold Forster's Observations, and the verbal Account of some of the most Knowing of the Navigators: with some Anecdotes that happened to them among the Natives." The list describes thirty-nine specimens, whilst this copy contains forty-three, four samples having apparently been added since the book was originally published. The *Museum Journal* for March, 1921, reprints the catalogue, with useful notes and descriptions of the method of preparing tapa cloth.

"The *Rôle* of Meteorology in Malaria" is the subject of a paper by Brevet Lt.-Col. C. A. Gill (*Indian Journ. Med. Research*, vol. viii., No. 4, 1921, p. 633). Col. Gill finds that whilst humidity exercises no direct effect on the malaria parasite in the mosquito, the survival of infected insects during and beyond the incubation period of the parasite in its insect-host is dependent upon the occurrence of certain favourable degrees of relative humidity over a wide range of temperature. On the other hand, the completion of the developmental stage of the parasite in the mosquito is determined by the association of relatively high temperature with relatively high humidity. The meteorological circumstances favourable to mosquito life and to the transmission of infection are thus not identical, and no relationship need, therefore, exist between the distribution of the carrier insect—the mosquito—in Nature and the distribution of endemic malaria.

Dr. R. J. Tillyard deals with the Neuropteroid insects of the Hot Springs region of New Zealand in relation to the problem of trout-food in vol. iii. of the *New Zealand Journal of Science and Technology* (Nos. 5 and 6, 1921). Observations made in various parts of the world, as well as in other regions of New Zealand, show that the larvæ of caddis-flies form one of the most important foods for the trout. In the district under consideration Dr. Tillyard states that the depredation caused by excess numbers of trout has enormously reduced the original fauna of these and other Neuropteroid insects which serve as food for this fish. In fact, the present position of the trout-fisheries in the Hot Springs region is such that there is not enough food for the trout present. It is clear that improvements can be effected along two distinct lines, viz. improvement of the food-supply and reduction in the number of trout. A series of recommendations is made by Dr. Tillyard in order to achieve this end.

The annual report of the Gresham's School Natural History Society for 1920 is an interesting and valuable record of the work done by a school society which is active and keenly alive to the importance of regional survey work. There are records of plants new to the district round Holt, of the insects collected by various members, of astronomical phenomena observed at the school, and of the first appearance of migratory birds in the neighbourhood. The most interesting record among insects is that of the first fully winged specimen of the Hemipteron, *Nabis boöps*, ever taken in Britain, captured by G. E. Hutchinson at Tidworth Pennings. One of the members, C. E. G. Bailey, has perfected and patented a self-tuning wireless apparatus which should prove valuable in expediting the work of wireless operators

in synchronising their apparatus to that of the transmitting section.

BULLETIN 702 of the United States Geological Survey contains information on the oil possibilities in and around Baxter Basin, Rock Springs Uplift, Wyoming, and is the work of A. R. Schultz. Little work has hitherto been carried out in this area, although geologically it has long been favoured as a likely field, but latterly active interest has been taken in its development, and consequently the presentation of this official report is of much importance. The Rock Springs Uplift consists of an enormous dome of Cretaceous and Tertiary strata rising in the middle of the horizontally bedded rocks of the well-known Green River Basin, the dome itself being much warped into minor folds; Baxter Basin is situate in the central part of this dome, and consists structurally of a broad eroded anticlinal involving the Mesaverde, Blair, Baxter, Frontier, and Aspen series (in descending order) of Upper Cretaceous age, with probable representatives of much older formations. Oil occurs at several horizons, but the Frontier series, the principal oil-bearing series in Wyoming, lies at a depth of some 5000 ft. below the surface, which is almost the limit here for drilling. In addition, there are the extensive deposits of oil shale, the Green River formation of Tertiary age, surrounding the central area of the Rock Springs dome, and development of these should prove successful. Recent drilling on the Baxter Basin anticline has been carried out with promising results, mainly by three companies, small quantities of oil and a flow of gas at several hundred pounds pressure being obtained. This is a field of which we shall undoubtedly hear more in the course of time, and the Geological Survey officers are to be congratulated on the large amount of valuable preliminary information here published as an aid to its development.

IN Bulletin 713 of the U.S. Geological Survey (1920) there is an illustration of a recumbent cedar in vigorous growth, a member of a grove of similar habit on a wind-swept slope in Idaho. Physiographers and students of forestry will like to compare it with the drawing of *Pinus montana* in its climbing attitude in Brunhies's "Le Parc National Suisse" (NATURE, vol. cvi., p. 466).

WE have recently received a copy of part 3, vol. xl., Mem. Geol. Surv. India, by E. H. Pascoe, dealing with the occurrences of petroleum in the Punjab and North-West Frontier Province, which, though somewhat belated owing to the war and other circumstances, makes a welcome appearance just when first-hand information concerning our Imperial oil resources is required. The main petroliferous region occupies a belt flanking the Himalayas and traceable westwards from Simla, though it is not clearly defined until the division of Rawal Pindi is reached; it extends for 140 miles across the Indus through Kohat and Bannu and southwards into Baluchistan. The altitude of this belt suggests relationship to two distinct systems of tectonic movement: that of the Himalayas to the east, with their north-west to south-east trend in this region, and that of the Afghanistan-Baluchistan system to the west, a somewhat complex series of tectonic elements with a general curving strike from north to west, here recognised as the Attock arc. The belt lies in the re-entrant between these two systems, and occupies the site of an ancient river valley (Indobrahm), much in the same way as the petroliferous belts of Burma and Assam are coincident with ancient river-courses. Geologically the belt is divisible into halves, a northern and a southern, separated by a broad synclinal area. The northern half embraces the occurrences of oil around Rawal Pindi, in the Kala Chitta Hills, at Khaur, and in the trans-Indus salt area; the southern includes those of the salt range with the seepages of the Khasor Hills. Structurally the oil and gas are associated with anticlines involving rocks of Nummulitic or Muree age, the trend of these anticlines conforming to the main tectonic features existent at the particular locality at which they occur. Although the occurrence of petroleum in this part of India has been known of for many years, exploration has not met with unqualified success save in the case of the Attock Oil Co., which has carried out developments at Khaur. The oil obtained at Khaur varies in specific gravity from 0·894 to 0·876 in the upper sands, and from 0·877 to 0·840 in deeper sands, and is generally darker in colour than Burmese oil. The author regards the origin of the oil in this region as doubtful, though it would seem to be indigenous to the Nummulitic beds, its occurrence in the overlying Muree beds being probably due to upward migration.

THE subject of climatic conditions on the principal air routes in the East Indian Archipelago has been recently dealt with by Dr. C. Braak, of Batavia. Dr. Braak is of opinion that from an international point of view the air route from Singapore to Port Darwin is the most important. Relative to the different conditions in the tropics and in temperate latitudes, he asserts that in the tropics higher temperature at the surface is responsible for lighter air for aeroplanes at the start, but the wind conditions are said to be strongly in favour of the tropical climate. Cyclones are rare in the Archipelago, their occurrence being limited to the month of April and to the late days of March and early days of May, whilst there is usually only one in each year. The variability of wind direction is relatively small, and the wind variations are principally reinforcements and weakenings of the monsoons. A feature favourable to aerial navigation is stated to be the well-marked and very regular daily variation in most of the meteorological factors, so that choice can be made of the time of day that affords the best flying conditions. Details are given of the surface winds, as well as of the air movement in the higher levels. Monthly rain measurements and the number of rainy days are tabulated for many places within the area. The distribution of rainfall over the day is shown, as are also frequency of thunder, relative cloudiness, and haziness. It is stated that when comparison is made with the climatic conditions in temperate latitudes the conditions in the Archipelago may be called rather favourable.

IN the Bulletin of the Central Meteorological Observatory of Japan (vol. iii., No. 3, Tokyo, 1921)

Sin-iti Kunitomi and Hikotarô Takô discuss the correlation between the fluctuation of solar activity, as shown by sun-spots and faculæ, and the terrestrial precipitation of rain, as measured at Tokyo and other stations in Japan and Japanese territory elsewhere. The Greenwich records were drawn on for the solar data, and the periodogram method was applied to these and to the rainfall statistics. The investigation suffers from the paucity of the latter material, which is limited to a period of three years; the authors state that only when the influence on the rainfall, of other than solar causes, was eliminated by the periodogram treatment was it possible to obtain any significant correlation coefficients at all. Even so, they suggest that the relation between the solar activity and the precipitation is likely to be somewhat indirect. To the reader acquainted with studies of this kind it will probably appear that the amount of material used was inadequate to allow of even the most tentative conclusions being based upon it. The authors recognise the necessity for further discussion, and promise a more elaborate study of the subject later.

The August issue of the *Philosophical Magazine* contains the concluding portion of Dr. N. R. Campbell's paper on the disappearance of gas when an electric discharge is passed through more or less exhausted tubes, a subject he has investigated for the General Electric Co. His observations cast serious doubt on the results which have been obtained by many previous workers, according to whom Faraday's laws of electrolysis hold in gases. Dr. Campbell finds, on the contrary, that the current arriving at the electrodes is not related in any simple way to the ionisation and recombination—that is, to the chemical reaction—taking place in the gas. The current, for example, at the cathode is made up of positive ions arriving and electrons leaving, and while the latter process is closely connected with the former, the two processes are not likely to be connected with the rate of progress of the reaction in the gas in the same way.

After an interval of seven years the Geological Society of London has been able to resume the issue of its annual index to "Geological Literature Added to the Geological Society's Library," which is so complete a work of reference, both to subjects and to the output of individual authors. The present part (5*s.*) brings the matter down to the close of 1913.

Our Astronomical Column.

The August Meteoric Display.—Mr. W. F. Denning writes that on August 8 several fine meteors were observed by him at Bristol, and they belonged to the well-known shower of Perseids. On August 11, watching for two and a quarter hours before midnight, he counted 134 meteors, although the moon in her first quarter was shining brightly nearly all the time. The display was an exceptional one as regards both the number and the brightness of the meteors. Of the total number seen, 122 were Perseids and 12 belonged to the minor showers of the period. The radiant point of the Perseids was at $44°+57°$, but it was not so sharply defined as it sometimes is.

About 33 of the meteors seen were equal to, or brighter than, stars of the first magnitude, and they exhibited the swift motions and luminous streaks which are characteristic of the August meteor swarm.

Clouds came over the sky at 11.50 G.M.T. and prevented observations in the morning hours, but there probably occurred a very rich exhibition of meteors at places where the stars were visible. On August 12 the firmament was partly cloudy at Bristol, but there was a considerable number of meteors to be observed, for in clear spaces they were frequently seen, though no continuous observations were made. At 2.30 a.m., G.M.T., four Perseids were seen in less than two minutes, but immediately afterwards clouds interfered.

Mr. C. P. Adamson, of Wimborne, Dorset, watched the sky during two and a quarter hours on the evening of August 11, and counted 131 meteors. His results, therefore, as regards the numerical strength of the shower are in close agreement with those obtained at Bristol. Mr. Adamson found the radiant point elongated, from $43°+57°$ to $49°+58°$. Of the total number of meteors seen he says there were 125 Perseids, and at least 50 per cent. were equal to, or brighter than, first-magnitude stars.

The Bright Object near the Sun.—Three of the five observers of this object, referred to in last week's issue, p. 759, were Prof. Campbell and his wife, and Prof. H. N. Russell, who is staying at the Lick Observatory. The object was seen shortly before sunset; the fact that it partook of the diurnal motion indicated that it was a celestial body. Prof. Campbell observed it with binoculars, and noted that it still appeared stellar, which favoured its being a nova. If so, it is probably the most brilliant since that of Tycho Brahe. The approximate position is R.A. 9h. 22m., N. decl. 16°. The galactic latitude is about 40°. The object does not appear to have been seen since August 7. It may be recalled that the great 1882 comet and that of January, 1910, were seen close to the sun.

A report from Königstuhl Observatory, near Heidelberg, states that on the night of August 8–9 a number of luminous bands lay across a clear sky from W.N.W. to E.S.E.; they moved slowly towards N.N.E., growing paler as the dawn came. It was conjectured that it might be the tail of the light object seen at Lick Observatory on August 7, passing very near the earth. It will be recalled that a somewhat similar phenomenon was reported when the earth passed through the tail of the great comet of 1861 on June 30 of that year.

It seems possible, however, that the present streamers may have been auroral, as the cometary nature of the Lick Observatory object is still in doubt.

Continuation of the Ephemeris of Eros.—This planet was photographed at the Algiers Observatory in July, within 3′ of the predicted position. The following ephemeris, for Greenwich midnight, is by Mr. F. E. Seagrave, corrected approximately by observation:—

	R.A. h. m. s.	N. Decl. ° ′		R.A. h. m. s.	N. Decl. ° ′
Aug. 20	23 25 41	12 20	Sept. 9	22 52 56	13 57
24	23 20 18	12 52	13	22 45 22	13 57
28	23 14 13	13 18	17	22 37 54	13 49
Sept. 1	23 7 32	13 38	21	22 30 44	13 35
5	23 0 23	13 51	25	22 24 3	13 16

Values of log r, log Δ, August 20, 0·2249, 9·8676; September 25, 0·2026, 9·8064. The magnitude in mid-September will be 10·5. The planet will thus be easily accessible in ordinary telescopes. Accurate observations of position are desired

University Education in the United States.

THE Washington Bureau of Education has just issued Bulletin No. 87, dealing with certain statistics of State universities and colleges in the United States of America for the year ended June 30, 1919. This is an annual publication which was formerly prepared and published by the National Association of State Universities, and contains data relating to ninety-two public institutions of university rank. The total enrolment in these State institutions for the year 1917–18 was 110,900, as against 244,231 in the corresponding private institutions. In 1918–19 the lowest enrolment was 31 for the New Mexico School of Mines, and the highest 8857 for the University of Michigan. With regard to teaching staff, the numbers in the State institutions vary from 7 to 908, the latter being the number of teachers in the University of Minnesota in 1918–19. It is curious to find that the University of Michigan with its 8857 enrolments shows an average of 20 regular term students per teacher, while the University of Minnesota with an enrolment of 6095 has an average of only 7. What is perhaps more curious is the fact that the total working income of the former is 3,069,587 dollars, while that of the latter is 3,462,361 dollars.

The fact that the institutions to which the bulletin has reference are passing through a stage of financial stringency very similar to that which is being experienced by the British universities at the present time gives an added interest to the publication. In the American State universities, just as in this country, "the cost of salaries has not risen to the same extent as the cost of living," and, as the bulletin very pertinently says, "unless the people wish to see their higher institutions staffed with men of inferior ability, it will be necessary to pay salaries sufficiently large to attract teachers of merit and ability." University teachers in this country will recognise a familiar ring about this language! The bulletin contains a mass of statistics which have been compiled by the Bureau of Education in the hope that they will be "very useful in the promotion of State campaigns for the more adequate support of higher education." While one may express the hope that American State universities and colleges will receive such public support in the future as will be necessary for their development, it should be observed that already they receive in the aggregate almost 73 per cent. of their income from public funds. In four States, indeed, the percentage is more than 90. In this country, notwithstanding the recent additional grant of 500,000*l*. to the universities, State aid is greatly inferior to the State aid which is given to public institutions in America.

Of special interest is the question of students' fees in these universities and colleges. At the outset one must make a clear distinction between public and private universities or colleges in America. The number of students enrolled in the public higher institutions amounts to about 31 per cent. of the whole, while the remaining 69 per cent. are enrolled in private or non-State-aided institutions. As a rule, the former pay small fees. In the case of New York University the income from fees is as low as 3 per cent. of the total income. The average for the whole country in 1917–18 was 22 per cent. of the total income. In the private institutions the percentage for the same year varied between 17 (Connecticut) and 87 (Alabama), with an average of 54 per cent., the remaining income being derived mainly from "productive funds" or private benefactions. So far as the State institutions are concerned there is no indication that students' fees, though lower than those in this country, are to be increased. The campaign to increase the income is apparently to be directed to obtaining increased assistance from public or State funds. The plea for State aid is concisely expressed in the words:—"When the State appropriates money to education, it is making a wise investment which will yield manifold returns. Liberal support of higher education is good public economy and wise forethought for the future." One may be allowed to hope that the Government of this country will ponder over these words. Our home universities are sadly in need of further State aid.

Recent Work on Minerals and Rocks.

NOW that questions of crystal structure and of approximate isomorphism play so large a part in chemical and physical conceptions, the study of crystallography is no longer for specialists alone. Students of many branches of science will welcome the re-issue of J. B. Jordan's nets for making models of simple crystal-forms (T. Murby and Co., London, 3*s*.). The older names can be covered by labels bearing those suggested in this edition, though we should like to see "bipyramid" substituted for "pyramid" throughout, since no true pyramids, such as those occurring in tourmaline, are utilised. These models were familiar in the Royal School of Mines forty years ago, and should now serve many future generations of students whose outlook on crystals has widened with physical research. Their effective colours and their price certainly commend them.

A. D. Hall provides a very interesting memoir (Union of South Africa Geol. Survey, No. 15, 1920, 7*s*. 6*d*.) on "Corundum in the Northern and Eastern Transvaal," in which the modes of occurrence and of working are fully illustrated. The author, in a chapter on "The Problem of Genesis," very properly directs attention to the tardy recognition of corundum as a rock-forming mineral, and lays stress on the experimental work of Morozewicz in 1899. Corundum in the Transvaal arises from a granite magma supersaturated with alumina. Hall holds that this supersaturation arises, not through absorption of aluminous material from contact-rocks, but by removal of silica into those rocks along the zones of contact.

In "Phosphate in Canada" (Canada Depart. of Mines, No. 396, 1920) Hugh S. Spence describes and illustrates the well-known occurrences of apatite in Ontario and Quebec, and discusses works established in other parts of Canada where imported phosphatic materials are used. The apatite "is to be considered of igneous origin rather than to have been derived from the original limestones" through which the pegmatite masses have passed. The associated minerals, such as pyroxene, scapolite, and phlogopite, are described. At Huddersfield, Quebec, allanite occurs in crystals more than an inch in diameter, and fluorspar, which is here abundant in calcite, assumes a deeper violet colour in close proximity to it. An emanation-influence naturally suggests itself.

The minerals of saline lakes, notably epsomite, are dealt with by L. Reinecke in "Mineral Deposits between Lillooet and Prince George, British Columbia"

(Canada Geol. Survey, Mem. 118, 1920). R. Lockhart Jack, in "The Salt and Gypsum Resources of South Australia" (Geol. Surv. S. Australia, Bull. 8, 1921) interestingly connects the salt of the lagoons of the Yorke Peninsula, between Spencer Gulf and the Gulf of St. Vincent, with "cyclic" salt imported aerially during long ages from the sea. The supply thus given to the soil is drawn on by the lakes, with, of course, some addition from salt-dust now falling on their surfaces, and depends on conditions of dryness, whereby the local water-table does not rise dangerously high. The meteorological features of the region are well put forward. The deposits of gypsum are similarly attributed to cyclic matter, which has been redissolved and carried by the saline ground-waters (p. 90) into lake depressions. On the margins of these it evaporates and becomes blown up into dunes. There are also some occurrences of gypsum in a more normal and less interesting manner in Cainozoic rocks.

The graphite deposits of the world outside the United States are reviewed, with maps, in a valuable paper by A. H. Redfield ("Foreign Graphite in 1919," U.S. Geol. Surv., Min. Resources, 1919, part ii., No. 12, 1921). This pamphlet should stand beside our text-books of mineralogy, which constantly require the refreshing influence of general surveys of this nature. Though the commercial aspect is naturally paramount, the names of localities and the references to literature will be of service to the student.

The work of R. E. Liesegang has added considerably to the interest of zoned and banded deposits. P. A. Wagner (Trans. Geol. Soc. S. Africa, vol. xxiii., p. 118, 1921) describes the "Nature and Origin of the Crocodile River Iron Deposits" in the Rustenburg district of the Transvaal. He compares them with those of the Lake Superior region, and holds that the hæmatite and hydroxide masses are concentrations by downward percolation from beds of siderite and ferruginous chert. In some cases alteration in place has led to the formation in chert of magnetite, hæmatite, or brown hydroxide, alike pseudomorphous after rhombohedral siderite.

Olaf Holtedahl (*Amer. Journ. Sci.*, vol. cci., p. 195, 1921) reviews old and recent work on the zoned concretions of calcite in the magnesian limestone of Durham, pointing out the reasons that have led English geologists to regard them as mineral structures arising through secondary alteration. Their resemblance to some of the pre-Cambrian structures claimed by Walcott as algal (Camasia, Newlandia, Greysonia, etc.) inspires the author with caution in dealing with these older specimens.

Mineralogists cannot afford to overlook the paper by F. W. Clarke and W. C. Wheeler on "The Inorganic Constituents of Marine Invertebrates" (U.S. Geol. Surv., Prof. Paper 102, 1917) with its important series of analyses of the hard parts of a wide range of living creatures. The proportion of magnesium carbonate to calcium carbonate bears, of course, on the much-discussed origin of dolomite, and it is shown that organisms capable of depositing calcite may accumulate magnesium by isomorphous substitution, while this cannot take place when the hard parts are formed of aragonite. The utilisation of magnesium is very distinctly favoured by warm conditions, specimens from Arctic or Antarctic waters, or from very deep waters, showing relatively small proportions. Crinoids, for instance, from 47° N. lat. and a depth of 1000 metres may yield 9 per cent. of magnesium carbonate, while 12 per cent. commonly occurs at similar depths near the equator. A biological problem of much interest is here opened. No such authoritative and detailed analyses have hitherto been available. As was already known, alcyonaria generally are rich in magnesium carbonate. An equatorial specimen of *Phyllogorgia quercifolia* is here shown to contain 15·73 per cent. The influence of these facts on determinations of specific gravity in fossil forms should, of course, be noted.

The rhyolites of Lipari, including the familiar obsidian of the Rocche Rosse, have received complete and critical examination and analysis from H. S. Washington (*Amer. Journ. Sci.*, fourth series, vol. l., p. 446, 1920). It is shown that in the glassy varieties ferrous oxide predominates largely over ferric oxide, while this condition is reversed in crystalline types. It is suggested that the glassy state retains more nearly the constitution of the igneous magma, while oxidation occurs as the gases are permitted to escape.

W. R. Browne provides a new study of differentiation in an igneous mass, through the sinking of crystals and later extrusions, in his description of "The Igneous Rocks of Encounter Bay, South Australia" (Trans. Roy. Soc. S. Australia, vol. xliv., p. 1, 1920). In the same volume, p. 300, W. Howchin reviews coarse fragmental structures of various kinds in rocks, citing Australian examples, and he usefully directs attention to the influence of desiccation in breaking up a sediment in an early stage of its history. The drying mud of lakes is an example. Attention may be directed to the moderate price (10*s.* 6*d.*) of this volume and of some other illustrated publications from our federated Commonwealths, in the hope that the enterprise displayed may react on issues in the homeland.

G. A. J. C.

Plant Pests and their Control.

By DR. WILLIAM B. BRIERLEY.

THE "Report on the Occurrence of Insect and Fungus Pests on Plants in England and Wales for the Year 1919,"[1] which has just been issued by the Intelligence Department—Plant Pests Branch of the Ministry of Agriculture and Fisheries, marks a very definite step in the recognition in this country of the danger to our food crops from diseases caused by insects, fungi, bacteria, etc. This disease-survey work was originated by a sub-committee of the Technical Committee of the late Food Production Department, which was formed to advise the department on questions relating to plant disease and insect pests. A few honorary correspondents scattered throughout the country forwarded monthly statements relating to diseases and pests in their own particular areas, and at the close of the year these were summarised by the sub-committee, and a "Report on the Occurrence of Insect and Fungus Pests during 1917" was published. This was the first time that any successful attempt had been made to gather together and systematise data relating to the incidence and spread of plant disease in this country. With the experience gained the work was continued in a more efficient manner, and a report for 1918 issued. There has now appeared the present, and somewhat belated, report for 1919, and a comparison of these three publications

[1] Ministry of Agriculture and Fisheries. Intelligence Department: Plant Pests Branch. (Miscellaneous Publications, No. 33.) "Report on the Occurrence of Insect and Fungus Pests on Plants in England and Wales for the Year 1919." Pp. 68. (London: H.M. Stationery Office, 1921.) 1*s.* 6*d.* net.

shows a marked progress in width and inclusiveness of vision. A mass of valuable data has been accumulated, and the Ministry, by becoming acquainted with those areas where disease is most serious, is in a better position to advise and to urge measures of control. Further, the Ministry must lead the way, and by the recognition of those diseases most responsible for heavy losses, it will be enabled to suggest, or institute, policies which will lead to the prevention of the present appalling waste of foodstuffs.

The report for 1919 is divided into three sections, the first being a tabulated and summarised list of the correspondents' reports on insect pests received during the year. The second section is a complete and up-to-date hand-list of the authenticated fungus diseases in the country, and if expanded and elaborated would form a very useful reference book for plant-pathologists, filling a niche at present singularly empty. The third section is a summary of meteorological data with which the incidence and spread of disease might be correlated. The report is a notable achievement, and a fine example of the solid scientific work which, quietly and unassumingly, is being carried out by this branch of the Ministry of Agriculture. Much credit is due to Messrs. Fryer and Cotton, who, in the face of not a little discouragement and lack of aid, have carried this work through to such a pitch of efficiency and permanent value.

There are naturally many features at which one could cavil, but these are due primarily to the exigencies of the incomplete and voluntary system on which the field reporting necessarily is based, and upon the innate difficulties in the reporting itself. Thus whilst it is important to learn that a particular disease is present in certain localities on specific dates, the really important thing in this connection is to find out what, if any, relation exists between the several outbreaks, and what relation the outbreaks bear to climatic conditions and dispersive factors. The acquiring of such knowledge, however, is a considerable piece of research, needing the whole-time services of a large *personnel* of highly trained investigators, and these the country does not possess, nor will it until plant disease is regarded a little more seriously by the university and the farming mind. Again, to learn that "Mosaic Disease is present in tomatoes grown in the open," is interesting, but one would like to know exactly what percentage of the plants are killed or sterilised by this disease, or of those in bearing what percentage of a normal yield is obtained, and what is the financial loss incurred by the trade? The present lack of standardised criteria in loss estimation is very unsatisfactory. However, these are questions easy to ask, and almost, if not quite, impossible to answer, and only slightly detract from the value of this report as a foundation for epidemiological study in plant disease.

But the preparation of such a report as this has a far greater value than its local interest. Plant diseases are no respecters of diplomats or political boundaries. The disastrous spread into this country of American gooseberry mildew, or wart disease of potatoes; of citrus canker and chestnut bark disease into America; the wiping out of the coffee industry in Ceylon by the introduction of the coffee leaf disease into that island—the remembrance of these among many examples that could be quoted, should convince everyone of the critical importance of an accurate and systematic survey of plant diseases in order that undesirable aliens may be excluded, or if found to be present, crushed whilst still limited in distribution.

The control of plant disease in our crops is one of the most vital factors in agriculture to-day, and in the lean years to come, when every ounce of food will be an asset, the knowledge gathered together in such reports as this will be a very material aid in the struggle to provide the nation's sustenance.

Studies of Shore Fishes.[1]

NOT the least of the Danish marine expeditions in the *Thor*, under the skilful hands of Dr. Johs. Schmidt, was that devoted to the careful search of the Mediterranean and the sifting of the work of Grassi and Calandruccio in regard to the spawning of the eel and the murenoids.

In the course of this work many young shore-fishes were encountered, and M. Louis Fage has given an excellent report thereon. Some of them are common to British waters as well as to the Mediterranean, whilst others, such as Macrorhamphosus, Anthias, Callanthias, and Uranoscopus, are more characteristic of the southern waters. Though the shores of the Mediterranean are rich, they fall far short of the plenitude and variety of the shore-fishes of Japan. Of the twenty families encountered, thirteen have pelagic eggs and seven demersal. The striking changes between the adult outline and that of the young are well shown in such species as *Macrorhamphosus scolopax*, the gurnards, *Serranus cabrilla*, and *Anthias sacer*. The illustrations appear to have been made from preserved specimens, and in a characteristic form like the grey gurnard in its early stage the pectorals fall short of the actual proportions (*cf.* Prof. Prince's figure from life, Trans. Roy. Soc. Edin., vol. xxxv., pl. xvii., Fig. 5).

Perhaps the most interesting part of M. Fage's memoir is the introduction, in which he discusses the problems connected with the reproduction of the Teleosteans. Amongst other features, he believes with Giard that the embryology is condensed as we advance to the north, yet that the pelagic embryos are specially adapted to the colder waters. Thus, taking the genera Sebastes and Scorpæna, the latter having two subgenera, Helicolenus and Scorpæna, it is found that *Sebastes marinus* is rare south of the Faroes, and is viviparous. The widely distributed *Helicolenus dactylopteris*, Delar., reproduces in winter in northern waters, and the larvæ agree with those of other Scorpænidæ. On the other hand, *Scorpaena porcus* and *S. scropha* in the southern waters are developed in summer, and their early pelagic stages have enormous pectorals for sustaining them. The larval stages of some of the fishes from southern waters are prolonged, *e.g.* *Arnoglossus laterna*, Will., as shown by Dr. H. M. Kyle, undergoes metamorphosis in northern water when 16 mm. long, but in the Bay of Biscay when 26–30 mm. in length.

M. Fage attributes the wide distribution of the young forms of certain shore-frequenting species to the cyclonic currents of the Mediterranean; but he has to except the young of the genus Callionymus. A wider view of the subject, however, creates doubt as to the general applicability of such an explanation. In connection with the adaptations of the larvæ he forms two groups (after Dollo), viz. the *nectique* and the *plantique*. The slow forms, especially the benthal, develop organs for maintaining equilibrium in the plankton, such as long ventral or pectoral fins

[1] Report of the Danish Oceanographical Expeditions in the Mediterranean, 1908–10. "Shore Fishes." By Louis Fage, of the Natural History Museum, Paris. Pp. 154. (Copenhagen: And. Fred. Høst and Son, 1918.)

or elongated dorsal fins, but the author does not allude to the slow lumpsucker, which has none of these characteristics.

Lastly, M. Fage refers to positive and negative heliotropism in the larvæ, the former being illustrated by the capture of the young *Capros aper* much nearer the surface by day than by night, and the latter by the passage of *Paracentropristis hepatus* from considerable depths by day to a more superficial area by night. The study of this subject, however, is still in its infancy. Many other interesting features are instanced by the author, whose memoir forms an important contribution to the subject of the larval forms of shore-fishes.

W. C. M.

The Lac and Shellac Industry in India.[1]

By DR. A. D. IMMS.

AT the present time India holds what is virtually a monopoly of lac production, and no satisfactory substitute has yet appeared on the world's markets. This monopoly cannot, however, be regarded as a sinecure; other countries are likely to be found suitable for lac cultivation, and the present high value of lac and its importance to many Western industries render it urgent that the production of this substance should be encouraged along improved scientific and economic lines. The propagation of lac is still very carelessly carried out, and its methods of collection need much improvement. The crop varies from year to year, prices fluctuate seasonally, and there is much injurious market speculation. The bulk of the world's lac comes from Chóta Nagpur, Orissa, the north-eastern half of the Central Provinces, some western districts of Bengal, and from part of the Mirzapur district of the United Provinces. Out of the ninety or more trees which have been recorded as hosts for the lac insect (*Tachardia lacca*), the most important include *Schleicheria trijuga, Butea frondosa, Zizyphus jujuba* and *xylopyrus*, together with species of Acacia, Ficus, etc. These plants contain much gummy or resinous matter or are rich in latex.

The problems concerning lac production are manifold, and may be roughly divided into (1) botanical, (2) entomological, (3) chemical, (4) cultural, and (5) technological. On the botanical side we need more especially to determine the optimum conditions which conduce to the food-plants yielding a heavy crop of lac. It also needs to be ascertained how far it is possible by cultural treatment to stimulate the plant's production of those substances which are utilised by the insect in lac secretion. On the entomological side the most important problem is to deal with the enormous number of parasitic and other insects which annually destroy a prodigious amount of lac, either directly or indirectly. It is extremely unlikely that any marked improvement in lac culture will result until this complex problem has been thoroughly gone into. On the chemical side we need to know what plant substances are essential as food or raw material for the lac insect. Once the biochemistry of this problem is understood, it will pave the way for a better understanding of the requirements of the insect and open up a whole field of research into the cultural conditions necessary.

Under the latter heading are many other problems. Pruning and pollarding are highly desirable, for the lac insect is dependent upon the existence of young shoots in the right physiological condition. The extent and frequency with which the trees can be safely infected to yield the optimum crop need to be ascertained. It is also necessary to acquire definite information whether the best results are likely to be obtained from the establishment of lac nurseries composed of young trees of convenient size under careful cultivation, or whether little benefit is likely to be derived, as compared with the present system of relying solely upon existing trees growing wild and distributed over wide areas. On the technological side much improvement is possible; we need to ascertain the best and most economic methods of dealing with lac in all stages of its treatment—from the condition when it is received as stick-lac up to the final products of shellac, lac-wax, and lac-dye. The present system is primitive and often uneconomic, and adulteration is frequent.

The problems are highly complex and involved, and this fact is fully appreciated by Messrs. Lindsay and Harlow in recommending that a central lac laboratory be established in India. Under the existing system most of what research has been done at all has been carried out partly by the Forestry Department at Dehra Dun and partly by the Agricultural Department at Pusa. Neither of the research institutes located in the above places has the necessary staff available for the work. The choice of a site for such a laboratory is likely to prove difficult, as there are many factors to be considered The *sine qua non* is that it must be located in an important area of lac production, where the problems can be studied on the spot. Such a laboratory would be devoted primarily to the study of the growing crop in relation to its environment. Its first aim presumably would be to obtain exact and trustworthy information bearing upon the many problems involved. At the present time we need new ideas and trustworthy knowledge. Much that is published is largely a repetition of what has appeared previously; the same statements, and often the same errors, have reappeared with perennial regularity, and little or no real progress has resulted. Messrs. Lindsay and Harlow's bulletin is a useful *résumé* of the present position of the problems concerned, and the suggestions which they bring forward will, it is to be hoped, receive the fullest consideration by those whose duty it is to develop and influence our means of utilising the natural resources of India.

Flight of Flying-fishes.

DR. E. H. HANKIN has made some interesting observations on the "flight" of flying-fishes (Proc. Zool. Soc. London, 1920, pp. 467–74, 2 figs.). He concludes that much depends on the atmospheric conditions. On a very still evening in the Arabian Sea he noticed that the length of a glide after leaving the water was only about a metre, and the fishes showed much lateral instability. During the same voyage, but in sunshine and with a light wind, the longer flights attained to between 200 and 400 metres in length. The pectoral fins are usually in the "flat" position, *i.e.* extended in the horizontal plane. Sometimes the wings are slightly inclined upwards, with the outer part of the fin at a higher level than its

base. This is the usual position in slow-speed flight. In rare cases the fins are inclined very slightly downwards, and this "down" position is probably used for flight at highest speed. Now soaring vultures have their wings in the "up" position for slow-speed flight, and use the "flat" wing-disposition for flight at high speed.

A further resemblance between flying-fish and soaring vulture is indicated by the observation that the tips of the pectoral fins may be bent up, forming an angle of perhaps 45° with the rest of the fin, which is comparable to the bending up of the terminal quills of the vulture's wing during horizontal soaring flight.

Dr. Hankin confirms the conclusion that while there may be flapping of the pectoral fins at the start, there is none after the fish has got well under way. A speed of 10 metres per second was observed during eight seconds, and a maximum of 20 metres per second is probable. Taking advantage of species of Exocœtus with coloured pelvic fins, Dr. Hankin was able to discover how the displacement of these is used to check the velocity in both high-speed and low-speed flight. In a species with the pelvic fins small in size and placed far forwards, therefore unsuitable for checking speed or for steering in the vertical plane, the fishes at the end of their flight steer downwards by drawing the pectoral fins back through an angle of about 45°. They then plunge head foremost into the water without any visible attempt to check their speed.

It seems that flying-fishes sometimes make mistakes as to the suitability of the air for flight. They may emerge with low-speed disposition when high-speed disposition would have been appropriate; they may emerge tail "up" when they should have tried tail "down." Thus their "flights" are often involuntarily short.

University and Educational Intelligence.

LONDON.—The Ph.D. degree in the faculty of science has been conferred on the following:—Connell Boyle (Royal College of Science), for a thesis entitled "Studies in the Physiology of Fungi"; Sri Krishna (East London College), for a thesis entitled "The Condensation of Phenols with Acid Anhydrides, with Special Reference to Coumarin"; Isabel Soar (Birkbeck College), for a thesis entitled "The Structure and Function of the Endodermis in the Abietineæ"; Nellie Barbara Eales (University College, Reading), for a thesis entitled "Monograph on the General Morphology of *Aplysia punctata*"; Frederick H. Newman (Royal College of Science, and University College, Exeter), for a thesis entitled "The Absorption of Gases in the Electric Discharge Tube"; and George N. Pell (University College), for a thesis entitled "The Trajectory of Bombs Dropped from Aircraft."

THE Bureau of Education, Washington, has issued a pamphlet dealing with the opportunities for the study of medicine in the United States (Higher Educational Circular, No. 22). The system of education in the United States is first briefly surveyed, and details are given of the preliminary studies and examinations necessary in order to enter a medical school. The medical curriculum is then described, and a list of the medical schools is given, with notes on their numbers of students, graduates, and teachers, and the fees. Other sections of the pamphlet deal with the expenses incident to an education in an American medical school, social opportunities, and scholarships and loan funds. Of the 85 medical colleges in the country, about 60 are open to both sexes.

Calendar of Scientific Pioneers.

August 19, 1662. Blaise Pascal died.—A religious philosopher, mathematician, and physicist, the author of the "Provincial Letters" and the "Pensées," Pascal spent the earlier part of his life in scientific studies. He made the first calculating machine, measured heights by the barometer, and with Fermat founded the theory of probabilities.

August 19, 1822. Jean Baptiste Joseph Delambre died.—During the French Revolution Delambre with Méchain made the geodetic measurements which formed the base of the metric system. He succeeded Lalande at the Collège de France, and distinguished himself as one of the secretaries of the Paris Academy of Sciences. His great "History of Astronomy" was published during 1817–21.

August 19, 1856. Charles Frédéric Gerhardt died.—An Alsatian by birth, Gerhardt became an assistant to Liebig, held a chair at Montpellier, and during the years 1848–55 resided in Paris, where he published his "Traité de Chimie organique," which contains his important views on the structure and constitution of chemical compounds. He died at Strasbourg, where a monument is to be erected to him.

August 19, 1896. Josiah Dwight Whitney died.—Graduating at Yale in 1839, Whitney rose to a foremost position among American geologists. In 1865 he became professor of geology at Harvard.

August 23, 1782. Henri Louis Duhamel du Monceau died.—A botanist, physicist, and technologist, Duhamel du Monceau had an unrivalled knowledge of timber, and as Inspector-General of the French Navy contributed to the advancement of naval architecture.

August 23, 1806. Charles Auguste de Coulomb died.—A French military engineer, Coulomb made important researches on friction, invented the torsion balance, and discovered the laws of the attraction and repulsion of electrified bodies. He was an original member of the French Institute, and was employed by Napoleon as an Inspector of Public Instruction.

August 23, 1835. Leopoldo Nobili died.—Nobili, who was professor of physics in the Archducal Museum at Florence, is remembered for the introduction of the astatic galvanometer and the thermo-electric pile.

August 24, 1664. Maria Cunitz died.—A native of Germany, during the Thirty Years' War Maria Cunitz removed to Poland, where, with the assistance of her husband, she compiled her astronomical tables, "Urania propitia . . ." From her universal accomplishments she was called the "Silesian Pallas."

August 24, 1832. Nicolas Léonard Sadi Carnot died.

August 24, 1888. Rudolf Julius Emmanuel Clausius died.—Both famous physicists, Carnot and Clausius are among the founders of thermodynamics. The son of the "Organiser of Victory," Carnot was born in the Luxembourg in 1796, passed through the Ecole Polytechnique, and served in the Army. His essay of 1824, "Réflexions sur la Puissance motrice du Feu," called by Kelvin an "epoch-making gift to science," for many years remained unnoticed. Clausius was born in 1822, and as a *Privatdozent* at Berlin in 1850 re-stated Carnot's principle, enunciated the second law, and afterwards developed his conception of entropy. His "Die mechanisch Wärmetheorie" appeared in 1867. While Carnot's work was the outcome of his study of the steam engine, that of Clausius led to the application of scientific principles to its improvement. The kinetic theory of gases also owes much to the labours of Clausius, who for some years was professor of natural philosophy at Bonn, where Hertz was his successor.

E. C. S.

Societies and Academies.

Paris.

Academy of Sciences, August 1.—M. Georges Lemoine in the chair.—The President announced the death of M. Edmond Perrier.—A. **Lacroix**: The mineralogical composition of rockallite. Dr. Charcot has recently made a successful landing on the island of Rockall, examined its geological structure, and collected specimens of the rocks. The present paper contains an account of the mineralogical, chemical, and spectroscopic examination of some of these.—L. **Maquenne** and R. **Cerighelli**: The distribution of iron in plants. Figures are given of 100 determinations of iron in various organs of forty species of plants. The quantities found are very small, varying from 1 to 362 parts of iron per million of dry plant material. Young organs, buds, and leaves contain more iron than the older ones.—A. **de Gramont** and G. A. **Hemsalech**: The conditions of the emission of the spark lines by the electric arc. Conditions of experiment were devised so that the effects of cooling the metallic vapours or the electrodes, of heating the electrodes, and of varying the chemical nature of the medium in which the arc was struck could be studied. The results prove that spark lines are always emitted when the current of the electric arc is obliged to pass through media (vapours or gases) possessing a relatively low degree of ionisation—that is to say, offering a strong resistance to the passage of the current. This amounts to saying that the emission of spark lines is related to the existence of intense electric fields.—L. **Antoine**: Perfect ensembles discontinuous throughout.—J. **Kampé de Fériet**: Certain systems associated with equations of finite differences or with partial linear differential equations.—H. **Beghin**: The Anschütz and Sperry gyrostatic compasses.—M. **Charcot**: An expedition of the *Pourquoi-Pas* to Rockall. An account of the landing of two men on the island on June 19 and of three men on July 1 for the purpose of collecting specimens of rocks and algæ.—E. **Dubois**: The minimum potential of electric discharge in hydrogen at low pressures. A further study of the variations produced in the discharge potential by the occlusion of hydrogen by the platinum wire electrode.—H. **Pélabon**: The resistivity of selenium. The resistance of liquid selenium falls rapidly as the temperature rises, the logarithm of the resistance being a linear function of the temperature. While the resistance of liquid selenium is defined by the temperature, this is not the case with the solid grey selenium, the resistance of which depends upon its previous heat treatment.—M. **Sauvageot**: The retarded solution and premature precipitation of cementite in eutectic and hypereutectic carbon steels.—A. **Damiens**: The system bromine–tellurium. The nature of the lower bromide of tellurium. Since bromine has no solvent action on $TeBr_4$, the thermal study is reduced to that of the system $TeBr_4$–Te. No indication of the compound $TeBr_2$ was obtained from the metallographic or thermal analysis, but this substance was proved to be present by heating in a vacuum. This gave a non-volatile portion and two sublimates differing in colour and volatility. One of these was $TeBr_4$ and the other a mixture of tellurium and its tetrabromide in the proportions required to form $TeBr_2$. Hence the lower bromide would appear to exist in the gaseous state, but is unstable in the solid state, decomposing into tellurium and the tetrabromide on solidification.—P. **Woog**: The oiliness of fatty bodies. The property of oiliness or greasiness, valuable in lubricants, is not capable of exact definition. The molecular volumes of a considerable number of lubricating oils, fatty and mineral, have been determined by cryoscopic or boiling-point methods, and it is shown that in general the oiliness or greasiness of an oil diminishes as the molecular volume decreases.—V. **Auger**: The equilibria of tri-, tetra-, and penta-valent vanadium in concentrated sulphuric acid solution.—C. D. **Zenghelis**: The detection of nitrogen in organic compounds. The compound is heated with a reagent consisting of soda-lime (two parts) and copper powder (one part), and the ammonia evolved detected by the formaldehyde-silver nitrate reagent previously described by the author. Tests with a large number of different types of nitrogen compounds are given, the limits of delicacy ranging between 0·05 and 0·001 milligram of nitrogen.—E. **Rengade** and J. **Clostre**: The estimation of water in transformer oils. The oil is heated to 80° C. in a current of dry air, and the escaping vapours are cooled with solid carbon dioxide or liquid air.—E. E. **Blaise**: The preparation of the acyclic δ-diketones. Glutaric diethylamide is condensed with an alkyl magnesium bromide. The reaction does not proceed normally, much gas being evolved, but the δ-diketone is formed, with a yield of 25 to 30 per cent. Dipropionylpropane and dibutyrylpropane have been prepared by this method: their properties and reactions are described.—H. **Gault** and R. **Weick**: Additional properties of the keto-enolic double linkage. A study of the reactions of one of the three isomeric phenylpyruvic esters with ammonia and diethylamine.—R. **Fosse** and G. **Laude**: Syntheses of cyanic acid and urea by the oxidation of organic substances: amides, nitriles, and methylcarbylamine.—M. **Samec** and Mlle. Anka **Mayer**: The synthesis of amylopectin by the phosphoric etherification of the erythroamyloses.—J. **Savornin**: The middle atlas of Morocco.—Ph. **Wehrlé**: The notion of period in the study of the nuclei of pressure variations.—A. **Carpentier**: The presence of Cycadophytes in the Wealdian layer of Féron.—L. **Blaringhem**: Researches on the hybrids of flax (*Linum usitatissimum*).—A. **Guilliermond**: Cytological observations on the bud of *Elodea canadensis*.—G. **Bertrand** and Mme. M. **Rosenblatt**: The general presence of manganese in the vegetable kingdom. According to Maumené, certain plants are free from manganese. The authors' analyses show that none of the exceptional cases cited by Maumené can be retained: manganese is present in all plants without exception.—S. **Metalnikow** and H. **Gaschen**: Immunity and hypersensibility in the caterpillar.—R. **Sazerac** and C. **Levaditi**: The treatment of syphilis by bismuth. A detailed account of the treatment and results in five cases.

Sydney.

Linnean Society of New South Wales, June 29.—Mr. G. A. Waterhouse, president, in the chair.—G. F. **Hill**: Notes on some Diptera found in association with Termites. In opening up galleries of *Mastotermes darwiniensis* and *Calotermes irregularis*, the author frequently found larvæ and pupæ of Trypaneidæ and Syrphidæ; he describes one species belonging to each family, that in the Syrphidæ being new.—Vera **Irwin-Smith**: Studies in life-histories of Australian Diptera Brachycera. Part i.: Stratiomyiidæ. No. 2: Further experiments in the rearing of *Metoponia rubriceps*. Attempts to rear the larval *M. rubriceps* from the egg have met with considerable success, and it has been found possible to breed from flies reared from the larva in captivity. The cycle, from larva to larva of the next generation, has been obtained, but the bred larvæ all perished at an early

stage, so that the cycle has not been quite completed, and the length of time passed in the larval state is still unknown.—Dr. R. J. **Tillyard**: Revision of the family Eustheniidæ (order Perlaria), with descriptions of new genera and species. The Eustheniidæ are described as a distinct family possessing only archaic family characters. To the three genera and four species which have been described the author adds two genera and seven species, all of which are described for the first time. The known distribution of the family is Tasmania, Victoria, New Zealand, mountains of East Australia, and southern Chile, and is regarded as an argument in favour of an Antarctic origin of the Perlaria.—Margaret H. **O'Dwyer**: Preliminary report on the nutritive value of certain Australian grasses. A number of grasses grown at the Botanic Gardens and at various State experiment farms have been analysed with the view of determining their value as foodstuffs. In order that the results might be of value for comparative purposes the material was obtained so far as possible at the following well-defined stages of growth:—(1) About half-way between the time when it begins to shoot and the flowering period, (2) early flowering period, and (3) when the seed is quite set. The paper comprises a preliminary discussion of the methods used and the results of the analyses.

CAPE TOWN

Royal Society of South Africa, June 15.—Dr. A. Young in the chair.—V. H. **Brink**: A preliminary genetic study on the osteology of the Griquas.—E. **Newbery**: Note on the life-period of the over-voltage compounds. A series of experiments has been carried out to determine the effect of changes in the speed of the commutator upon the measured over-voltage of various cathodes in dilute sulphuric acid. The commutator was rotated at speeds varying between 300 and 1500 revs. per minute, and an interesting set of curves was obtained by plotting the observed over-voltages against these speeds. The relative rates of decomposition or decay of the over-voltage compounds are shown by these curves. Those of zinc and chromium are so stable that no perceptible change of potential occurs within the time-limits of the experiments. The hydrides of silver, platinum, and graphite show signs of decay after one-twentieth of a second, those of copper and cadmium after one-thirtieth of a second, whilst those of lead and nickel appear to be decomposed with very great rapidity.

July 20.—Dr. J. D. F. Gilchrist, president, in the chair.—E. J. **Hamlin**: The effect of sunlight on secondary batteries.—Dr. J. D. F. **Gilchrist**: Note on the pectoral fin of Achirus (a species of sole).

University and Civil Service Salaries.

UNIVERSITY teachers, and not least those outside Oxford, will be grateful to the provost of Worcester College for his outspoken letter in the *Times* of August 15, in which he contrasts the higher salaries in the Civil Service with those of university professors and tutors in Oxford. The correspondence which this letter has evoked is most interesting, and raises certain points which have not escaped notice in these columns.

It may be recalled that the Select Committee on Estimates appointed by the House of Commons, in taking evidence regarding salaries, asked the representative of the Treasury questions regarding (1) comparable positions outside the Civil Service, and (2) stipends of university professors and tutors. The provost of Worcester College states that in Oxford "the stipend of the best-paid professorships was, and still is, 900*l*." In this connection it should be pointed out that the average stipend for a university professor in the other universities and institutions of university rank in England and Wales is about 850*l*. per annum, while not a few receive no more than 500*l*. a year.

On the other hand, there are many Civil Servants receiving double the salary that "the greatest learning and distinction can obtain at Oxford, and many receiving much more than treble such stipends." But this is not the full tale, for the salaries of the permanent heads of Government Departments are at present 3500*l*. per annum—emoluments considerably beyond those received by the highest-paid officials in the universities. The tutorial fellow at Oxford, with his modest 800*l*. a year or so, may perhaps be pardoned if he fails to appreciate the point of view of the writer of the letter to the *Times* who may be taken to represent the views of the Civil Service, when he plaintively refers to the fact that after September 1 the salaries of these permanent heads of Government Departments will be "only" 3000*l*. a year. And all the more so if he believes with the provost of Worcester College that "with few exceptions Civil Servants of the highest class are men who in intellectual attainments, by virtue of which as tested in examination they were appointed, fell considerably short of the standard of a tutorial fellowship at Oxford."

From the point of view of the university teacher, whose emoluments at their highest do not approach to anything like this figure, and at their lowest are mere pittances, the situation is not without irony or even humour. Notwithstanding the very favourable comparison with the staffs of the universities, the Civil Service, we are told, is under the impression that it has not received the consideration to which it is entitled, and apparently is advocating a reference of the whole question of its stipends to the National Whitley Council for the Civil Service! Now it is not our purpose to argue the pros and cons of this question. What we are immediately concerned with is the obvious inadequacy of the remuneration of university teachers. "Academic remuneration is a disgrace to the nation," says one of the correspondents—a Civil Servant—in the *Times*; "University professors are scandalously underpaid," says another; while the provost of Worcester College brings a serious charge against the Government by accusing it of having done much to make it impossible for the universities to attract and retain the service of the very ablest men. Such statements without further support might be open to criticism, but it so happens that they are confirmed by statistics and evidence collected by the Association of University Teachers,

to which reference has been made in these columns on previous occasions.

This is a very serious state of affairs and should give pause to thoughtful men. It is futile discussing the minor elements in the problem when the main facts are of so serious a nature. Whether a Civil Servant or a university teacher puts in more hours of work in a year is quite beside the point and from the very nature of the work impossible to decide. Equally beside the point is the fact that the nation's income from foreign investments has shrunk by a hundred millions per annum. The question is whether the university teacher is, under present conditions, adequately remunerated, and, if not, who is to blame. A permanent head of a Government Department receives 3000*l*. or more per annum, a headmistress of a council secondary school may rise to 700*l*. or 800*l*. a year, whereas an Oxford tutor or a professor in one of our modern universities receives on the average a salary of about 850*l*. a year. Is this just or equitable? Is it likely to maintain, let alone increase, the efficiency of the university by attracting to it the right kind of man?

The universities are doing work of the highest importance to the nation, whether it is examined from the cultural or from the utilitarian side. Without this work national life would be immensely the poorer, and yet the staffs are scandalously under-paid. Already this is reacting unfavourably upon the quality of the candidates for vacant appointments, and in course of time the reaction will become even more pronounced.

For this state of affairs the Government cannot escape criticism; we are in entire agreement with the pertinent remarks of the provost of Worcester College. The University Grants Committee is cognisant of the fact that university teachers are underpaid, and that the universities are more or less in debt. As their sources of income are limited, they naturally and properly look to the Government for further aid. An annual grant of a million and a half is quite inadequate, and, in proportion to the total Treasury grant towards education, wretchedly small. If the University Grants Committee cannot convince the Government of the necessity of augmenting the annual grant to the universities for the particular purpose of increasing the stipends of the staffs, it is about time a more representative body took over its functions.

Famous Chemists.

Famous Chemists: The Men and their Work. By Sir William A. Tilden. Pp. xvi + 296. (London: George Routledge and Sons, Ltd.; New York: E. P. Dutton and Co., 1921.) 12*s*. 6*d*. net.

SIR WILLIAM TILDEN, like many other persons, has been frequently struck by the general lack of knowledge, even among well-educated people, of the personal history and achievements of the men who have created epochs in science. This, however, need occasion no very great surprise. If the mass of the community are practically ignorant of science owing to the circumstance that they have been taught nothing concerning it, it is scarcely a matter for wonder that they should have no knowledge even of the names of its most distinguished votaries and no interest therefore in their lives and doings. Yet, as the author says, the story of their lives is not infrequently full of interest, even to those who are not specially attracted to science, or have little concern for its progress.

There has been, however, a great awakening of late. The lesson of our recent experience has been driven home. It required the Great War to enforce it. For generations past a few enlightened men have been preaching, with what seemed to many an almost tiresome reiteration, the truth that science in these days is more than ever at the basis of national welfare and security. The peril of the greatest crisis through which this country in all its long history has ever been confronted has at length aroused it to a recognition of this fact. It is unnecessary to dwell upon the evidence of this belated appreciation. We see it in the general anxiety concerning the present character and sufficiency of our secondary education, in the extraordinary rush of students into our university laboratories and lecture-rooms, in the more general recognition by manufacturers of the relation of science to industry, and, lastly, in the action of the Government in creating, on broad and liberal lines, a great scheme of State-aided endowment of science. The establishment of the Department of Scientific and Industrial Research, with its network of affiliated research associations throughout Great Britain, marks an epoch in the history of science of which it is impossible to exaggerate the significance and potentiality. Of course we must be prepared for wasted effort and wasted money. To muddle through is characteristic of our method. Science

is organised common-sense, and it is scarcely to be expected that a community which has hitherto had little training in the methods of science, and no opportunity of cultivating that habit of mind we designate as scientific, will work its opportunity with a maximum of economy. But the atmosphere thus created is bound to have its effect upon the general intelligence, and perhaps none of the many lessons of the war will prove to be more fruitful or more benign in its results.

One consequence, we may hope, will be a wider interest in, and a more generous appreciation of, the labours of those who have enriched science by discovery. Discovery begets invention, and invention begets wealth and prosperity, material comfort, and happiness in living. Science has innumerable gifts in her horn of plenty which she freely offers to her devotees who worship her assiduously and disinterestedly. But these gifts, precious as they are, seldom directly benefit those upon whom they are first bestowed. Those who receive them—the discoverers—give them away, with little or no expectation of material reward or worldly benefit to the inventors, who in their turn hand them on, on terms, to the rest of the community. It therefore behoves the inventors and the community in general, if only in common gratitude, to show some interest in the lives and fortunes of those who in the unselfish pursuit of truth for its own sake thus enrich their fellow-men.

The book under review appears at an opportune time. In it Sir William Tilden tells the life-story of a number of famous chemists, from the time of Boyle down to our own era. His work makes no pretension to be a history of chemistry. His purpose is to make the general reader acquainted with the personal history and work of certain prominent chemists, whose labours may be said to have been largely directed to a common purpose—the elaboration of the atomic theory. To apply Montaigne's phrase, he has gathered a posy of other men's flowers, binding them together with a silver thread of his own. This thread, which serves to connect the life-histories of a score of eminent chemists, is the conception of atoms as a theory of chemistry. From the wealth of material to his hand it was, of course, necessary to adopt some definite principle of selection. To the extent that the phenomena of chemistry are adequately explained by the atomic theory—that it is, in fact, the bedrock upon which the whole superstructure of the science rests—it may be urged that the work of every chemist conduces to its support, even when unconsciously directed to that end. Sir William Tilden has sought to draw a distinction between work that he regards as indispensable and that which is merely contributory but not essential to the establishment of the atomic doctrine, and on this ground he excludes all mention of many names that by common consent are certainly to be styled famous. This limitation has its difficulties, of which the author is no doubt well aware. It may be argued that the collective work of the chemists, British and Continental, of the Victorian era has done more to place the atomic theory on a firm experimental basis than all the labours of speculative thinkers from the time of Boyle to the death of Dalton. But the life-work of Laurent, Gerhardt, Stas, Kekulé, Hofmann, and Wurtz, as the author is constrained to point out, and with evident regret, finds no place in his book. On the other hand, it is difficult to see how the phlogistians he deals with, with the possible exception of Cavendish, contributed directly to the foundation of the atomic theory. Their work was for the most part wholly qualitative and empirical. Such work as that of Priestley or Scheele, for example, could afford no substantial basis for such a theory, except as supplying facts which enlarged the scope of the science. But this may be said of the work of every chemist who makes a discovery or pursues inquiry in the random method of Priestley.

In spite of the imperfection and limitations of the basis on which it is constructed, Sir William Tilden has put together a most interesting book which adequately fulfils the purpose for which it was written, which is to enlighten the general reader concerning the personal history and work of men who are distinguished for their services to chemical science and whose labours have permanently contributed, and to a noteworthy and memorable extent, to its development. The notices are pleasantly written, and care has been taken, whenever possible, to verify the biographical facts. The book is suitably illustrated with, for the most part, well-known portraits of the several chemists, and with occasional pictures of their laboratories and of apparatus which they employed. Perhaps the least satisfactory portrait is that of Proust. A better one is to be found in Jaeger's "Elementen en Atomen eens en Thans," which deals substantially with the same general theme as that of the book now reviewed, but carries it down, in its latest edition, to its newest developments, which are, indeed, partly dealt with by Sir William Tilden in the epilogue with which his book concludes.

History of Persia.

A History of Persia. By Brig.-Gen. Sir Percy Sykes. (In two volumes.) Second edition. Vol. i., xxviii+563; vol. ii., pp. xx+594. (London: Macmillan and Co., Ltd., 1921.) 70*s*. net.

THAT this book, first published in 1915, should already have appeared in a second and enlarged edition is a welcome sign of the times, if we may suppose that its popularity is due, not only to the attractive way in which Sir Percy Sykes has handled his subject, but also to the growing interest that is being taken in Oriental learning by many who before the war never realised the importance of such knowledge, and even now, perhaps, are but half aware how much depends on its cultivation and diffusion amongst us. Without understanding there can be no friendship, and without friendship no lasting peace.

Persia has a history of 2500 years, and what a history! Cyrus, Darius, Xerxes, Behistun, Persepolis, Marathon, Alexander and his successors, the Parthians, Ardashir, Shapur and Nushirwan, the wars with Rome, the overthrow of the Sasanian empire by the Arabs, Islam triumphant, Kerbela and the rise of the Shia, the Bagdad Caliphate, the revival of Persian nationalism, Seljuks and Assassins, the Mongol avalanche, Chengiz, Hulagu, and Tamerlane, the Il-Khans, the spacious times of Shah Abbas the Great, Nadir Shah, the Kajars, the Russian campaigns, the envelopment of Persia, the Revolution, the National Assembly and the first painful essays in constitutional government; all this, too, introduced by an account of yet more ancient civilisations which sprang up, flourished, and expired on Persian soil—Medes, Assyrians, Elam, Sumer, and Akkad—while in his closing chapters the author deals with political and military events of yesterday, including his own adventurous march on Shiraz, the Dunsterville mission, and the Anglo-Persian Agreement.

Obviously a work written on this scale must be either a compilation in the main or else the product of co-operative specialism, a method which will always appeal to students rather than to the general reader, and, in the present case, would probably have required ten volumes instead of two. It is no disparagement to Sir Percy Sykes to say that the chief merit of his history consists in the excellent use which he has made of his authorities, in the apt selection of materials, and in the skill with which they have been woven into a well-balanced and interesting narrative. To have accomplished so much, single-handed, is a remarkable achievement which easily outweighs some defects of detail and others of a more serious kind. Omissions, of course, were inevitable, but it seems extraordinary that only six lines could be spared for Rashidu'ddin Fadlu'llah, the Prime Minister of Ghazan and Uljaytu, equally eminent (to quote Prof. Browne) as a physician, a statesman, a historian, and a public benefactor, and beyond doubt one of the ablest men whom Persia has ever produced.

The author is at his best in describing actions and events; he can tell a story, he goes straight to the point, and his style is pleasing as well as vigorous. But with the inner or deeper side of his subject he is less at home, and here we find a tendency to emphasise comparatively superficial features instead of bringing out the essential. For example, in the notice of Omar Khayyám he gives a familiar reference to the poet's tomb, together with a photograph, for which we are grateful; but it might have been remarked that the quatrains attributed to Omar, and in part composed by him, derive importance from the fact that, being the work of many different hands, and having accumulated in the course of centuries, they exhibit the character, not of any individual Persian, but of Persia as a whole. This is a slight instance, and Sir Percy is so strong in most respects that he can afford to be a little disappointing in his treatment of literary topics, religious doctrines, dervish fraternities, and such matters as the influence of mysticism upon Persian political history. On the other hand, the strictly historical portion of the work is supplemented by chapters giving much useful information about geography, climate, fauna, flora, and minerals, inscriptions and monuments, architecture and art, etc.

The author knows the country well, and has a genuine, if not very profound, sympathy with its people. His two volumes are lavishly illustrated. For this reason alone, not to mention the pocket-maps which accompany them, they are valuable to students, while from what has been said concerning the range and variety of their contents it will be clear that they ought to find a place in the library of everyone who is interested in Persia.

The Kinetic Theory and the Quantum.

The Dynamical Theory of Gases. By Prof. J. H. Jeans. Third edition. Pp. vii+442. (Cambridge: At the University Press, 1921.) 30*s*. net.

THE first edition of this book was published in 1904, the second in 1916, and now, only five years later (and three of those were war years),

a new edition is required. By itself this indicates the value of the work, and it is also very satisfactory as showing the growth of interest in this important branch of mathematical physics. The main part of the book has scarcely been altered—indeed, too little so, for a good many of the misprints of the second edition have appeared again. In dealing with viscosity and heat conduction, Chapman's important work is given somewhat more fully than before; but it would, of course, be out of the question to reproduce in detail the stupendous formulæ which it involves. The only other point we will mention is to express a doubt whether the author's explanation of irreversibility really does explain that exceptionally difficult question. To put it in an extreme form, has anyone yet really discovered what distinguishes the past from the future?

The main changes are the additions at the end of the book, which deal with the quantum theory, and it must be confessed that we found these in some ways rather disappointing. A certain lack of harmony is produced by the policy of grafting a few chapters on the quantum on to the end of a book originally written before its existence was accepted. It must be recognised that it is a very difficult task to fit the subject in, for it is clearly right to give a complete account of the quantum; yet its field is a great deal wider than the mere kinetic theory of gases, so that its introduction necessitates the treatment of several other branches of physics, some of which are by no means elementary. What the author has given is certainly the most important part of the quantum theory—there is an excellent account of spectra, and also of the Debye theory of the specific heats of solids. The theories of Tetrode, Keesom, and others on the equations of state of gases, however, are barely mentioned; it is true they rest on much less firm foundations than the other questions, but still they are far more closely related to the subject-matter of the rest of the book, and their exposition would not have taken very long. Also the author gives only a very short discussion of the rotations of molecules, though there is direct experimental evidence as to their moments of inertia, and though Ehrenfest's formula for the specific heat of a gas is a type of function novel to the quantum theory. Again, it would have been interesting to have had more of an exposition of the method of solving problems by direct use of the relation of entropy to probability as typified by Planck's original calculation of the radiation formula. This method seems to us, on the whole, inferior to the author's, but it has been used a great deal, and must be understood by anyone who wishes to read the original papers of the subject.

In view of the greatly extended field that these chapters cover, only shortened proofs of many important theorems are given, and some of these are not fortunate. For example, in dealing with the displacement law of Wien the author states that the energy in each wave-length is unaltered during the change of wave-lengths, whereas in fact part of this energy is turned into work, and its disappearance is the essence of the process. Again, the author calculates the equilibrium between the energy of a vibrator and that of the surrounding electromagnetic field by finding separately the amounts of energy absorbed and emitted. This is essentially a problem of resonance, but in the calculation of the absorption the damping factor is omitted without justification. In this particular case the correct proof is no longer or more difficult than the author's.

In a subject like this, based as it is on very uncertain foundations, it must have been exceptionally hard to select what was sufficiently well established to merit inclusion. It will be seen that our chief quarrel with the author is that he did not give us enough. The book contains a great deal of invaluable information critically treated, which it would be hard to find elsewhere in English. If we have laid emphasis on the defects, it is because the excellences of the work are well known.

C. G. D.

Beast and Man in India.

Companions: Feathered, Furred, and Scaled. By C. H. Donald. Pp. ix + 159. (London: John Lane; New York: John Lane Co., 1920.) 7*s*. net.

THESE are vivaciously written reminiscences of Indian animals with which Mr. Donald managed to establish friendly relations. The first is the tale of a bear-cub, Bhaloo, with a strong sense of humour which became very expensive to his owner. The second tells of the rearing of two weaver-birds (*Ploceus baya*), which justified their reputation for inquisitiveness and educability. A weaver, "carefully and kindly taught, will, within a week, let off a toy cannon, select a particular number out of many cards, and bring it to his master; he will catch a two-anna piece which has been thrown into a well before it reaches the water, and bring it back. Some of his tricks seem absolutely incredible, and yet they are simplicity itself, and one and all may be taught in a couple of days each. The first and most important step in his training is to teach him that an open hand means food, and that a closed fist does not. Everything hinges on his mastery of

this secret, and the rest is simple." Of some interest are the instances given of apparent mistakes in building the wonderful nest, such as leaving no doorway.

The third companion was a flying squirrel (Pteromys), which moved along the ground in a succession of jumps, "rather a lumbering gallop," soon bringing fatigue. "The leap of the flying squirrel is said to be sixty to eighty yards, but I can safely say it is well over double that distance at times, as I have seen one go right across a valley nearer two hundred yards in extent." "On approaching the tree it means to settle on, the head is raised and the tail lowered so that the parachute then acts *against* the wind as a brake, bringing it slowly against the tree. The tail, to some extent, acts as a rudder, but the change of direction is really made by a slight drawing in of the extended limbs, on the opposite side to that to which the animal wishes to turn." Mr. Donald seems to have been happy with his varied companions, and they seem to have been happy with him. He tells us of his golden eagle (not, however, to be called Chrysaëtus, which spoils the name), of an Isabelline bear, a bull-terrier, a rock-python which could lift three chairs with its tail, and was happy on six crows every Sunday; of hawks and langurs; and more besides. He ends with a fascinating sketch of a fox, which suggests that the secret of domestication has not been lost. This is an enjoyable book, racy, objective, and shrewd, and it has excellent photographic illustrations. We like well enough some of Mr. Donald's pet names for his companions, such as Bhaloo for the bear, and Satan for the python; but Juggins for the golden eagle touches us on the raw.

Our Bookshelf.

Insect Life. By C. A. Ealand. Pp. xii+340+lxxiv plates. (London: A. and C. Black, Ltd., 1921.) 30*s*. net.

In this sumptuous and profusely illustrated volume Mr. Ealand attempts "to provide a text-book of entomology, useful alike to the serious student and to the reader who takes up the subject as a hobby." To us he appears to have fallen between two stools. The opening chapter on classification raised our suspicions when we encountered more than five pages of tabular classification of no possible value to the "serious student," for no hint is given of the basis employed, while to the reader with entomology as a hobby it is positively soul-destroying to be faced with a prodigious list of mere names. The second chapter, on social habits, colouring of insects, and economic questions, is more readable, provided one already possesses a considerable knowledge of insect orders and suborders. From chap. iii. onwards, however, the accounts of the several orders, etc., are of no value to the specialist, and of but little interest to the amateur. Nowhere do we find either an account or an illustration of the essential structure of an insect, or even of the mouth appendages; true, the serious student should know the main facts about these; but where will he be if his serious study should by misfortune begin with "Insect Life"?

Many of the illustrations are beautifully coloured and do immense credit to the publishers; but the object of the author seems to have been to arrange a striking plate rather than to display the structural features of the insects. Thus in the coloured plates of the Coleoptera many brilliant and beautifully coloured species are shown, but the majority have their legs tucked away out of sight beneath the body, so that the tarsal joints are entirely invisible, and in some cases the antennæ are in the same plight. The figures (copied from Shipley's "Zoology of the Invertebrata") showing the emergence of the dragonfly imago from the nymph are peculiarly unfortunately arranged, for, as in the original, instead of being placed vertically, the drawings have been turned round into a horizontal position, with the result that the dragonfly is shown emerging in a position that is absolutely impossible and absurd. It is unfortunate that so showy a book contains so little of real value.

A History of Psychology. By Prof. G. S. Brett. (Library of Philosophy.) Vol. ii., *Mediaeval and Early Modern Period.* Pp. 394. Vol. iii., *Modern Psychology.* Pp. 322. (London: George Allen and Unwin, Ltd.; New York: The Macmillan Co., 1921.) 16*s*. net each.

The first volume of this work was published in 1912. Starting with an account of primitive animistic notions, it carried the history through the periods of Greek philosophy and Greek Christian philosophy to St. Augustine. The two volumes now added deal, one with the medieval and early modern period to the end of the seventeenth century, the other with the modern period, ending with a final chapter on "The Scope of Modern Psychology." It is difficult to appreciate the purpose or the usefulness of a work of this kind, however much we may admire the devotion and research which have produced it. As an encyclopædia it is of little value, for the simple reason that one human author cannot be encyclopædic. He cannot be a first authority in regard to all the writers with whom he deals. Also it is misleading to describe animistic speculations or even philosophy of mind as parts of the science of psychology. As a matter of fact, the modern science of psychology has little or nothing in common with the theories here recorded, and owes nothing to them.

A more serious criticism, however, is a negative one. Information we naturally expected to

find and which might have made the history of real value is omitted. One illustration is typical. There is a chapter entitled "From Fechner to Wundt." If the reader should refer to it for an account of the psycho-physical law which has made Fechner's name famous, this is what he will find:—"The law known as the 'Weber-Fechner Law' has been so often described and discussed that we may be excused the task of repeating its definition." Practically all we are told about it is that "volumes have been written on it."

The Bases of Agricultural Practice and Economics in the United Provinces, India. By Dr. H. Martin Leake. With a foreword by J. MacKenna. Pp. viii + 277. (Cambridge: W. Heffer and Sons, Ltd., 1921.) 15*s*. net.

The author of this illuminating book has applied himself to the elucidation of the bases and development of agricultural practice and economics, showing how improvements in methods of farming must necessarily be associated with the due recognition of economic factors if true advance is to be made. Although the text deals solely with India, the underlying principles are applicable to agriculture the world over, and the book throws fresh light upon the new problems that are constantly arising now that scientific principles and methods are being more widely applied to farm practice.

Agricultural practice is essentially based on the relations between the soil and atmospheric conditions and the crops grown, and these are set forth factor by factor, careful distinction being made between those which can and those which cannot be controlled. Possibilities of development and improvement are discussed with special reference to such points as hybridisation and selection, cultivation and manuring, as adapted to Indian conditions. Parallel with this, the economic aspect is considered, particular stress being laid on the possibilities that lie in co-operation of various kinds as a factor in the encouragement of agricultural development.

The book is strongly to be recommended, not only to those connected with Indian agriculture, but also to all who are interested in the progress of modern scientific farming, for the conditions discussed are so varied that they provide scope for the consideration of strongly contrasted aspects of the subject. W. E. B.

Groundwork of Surgery. (For First-year Students.) By Arthur Cooke. Pp. viii + 183. (Cambridge: W. Heffer and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent, and Co., Ltd., 1919.) 7*s*. 6*d*. net.

Written by one who is himself a thinker, worker, and teacher, this book furnishes the beginner with an excellent introduction to the science, art, and craft of surgery. Most manuals are addressed by the expert to other experts, or at least to advanced students. In the present volume the author sets himself, very successfully, to lay the foundations on which a more detailed knowledge may be reared. The ground which surgery covers is indicated, and its broad outlines are defined; space is given to preventive treatment and surgical sanitation generally; and the main surgical affections of the different regions of the body are described. The book may be cordially recommended.

College Botany: Structure, Physiology, and Economics of Plants. By Dr. M. T. Cook. Pp. x + 392. (Philadelphia and London: J. B. Lippincott Co., 1920.) 12*s*. 6*d*. net.

It is said of this book by the author that it is "an effort to meet present conditions," but it is not very clear what these conditions are. The book is divided into sections on morphology, physiology, and classification, the last including general descriptions of the great plant groups. Some of the drawings, such as Fig. 30, representing a lenticel, and Fig. 152, depicting the pine cone and its parts, can only be described as crude; but the photographs of individual plants, of which there are many, are much more successful. A number of maps are given showing the various areas of crop production in the United States, and economic plants of all kinds are frequently introduced into the descriptions. The book would seem to be most suitable for American students beginning the study of agriculture.

Experimental Organic Chemistry. By Prof. A. P. West. (New-World Science Series.) Pp. xiii + 469. (London: George G. Harrap and Co., Ltd., 1921.) 10*s*. 6*d*. net.

Theory and laboratory experiments in organic chemistry are combined in this book. Only the more important compounds are discussed, and experiments of a difficult or dangerous character are purposely omitted. Review tables, giving at a glance the chemistry of groups of compounds, are supplied at frequent intervals. The theoretical part of the book is somewhat less satisfactory than the practical, for it is frequently very condensed. The book is well printed and illustrated. This is one of the very few elementary books on organic chemistry which give an accurate description of fractional distillation.

Reports of the Progress of Applied Chemistry: Issued by the Society of Chemical Industry. Vol. v. 1920. Pp. 626. (London: Society of Chemical Industry, n.d.) 15*s*.

The annual reports on the progress of applied chemistry issued by the Society of Chemical Industry fulfil the same functions for applied chemistry as do the annual reports of the Chemical Society for pure chemistry. They constitute a most useful and authoritative review of the work done during the year. The present volume is the work of experts in the various branches of applied chemistry, and can be recommended to all who wish to keep in touch with the rapid progress of chemical technology.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

The Natural History of Man.

IN an article on "New Experiments on the Inheritance of Somatogenic Modifications," in NATURE of February 3 (p. 742), Prof. Arthur Dendy writes: "It has long been suspected that the problem of the transmission from parent to offspring of somatogenic modifications ('acquired characters') might be solved more readily by physiological experiments directly involving the complex metabolism of the body than by crude surgical operations, such as the amputation of limbs." He proceeds to tell us of experiments which are thought to demonstrate that when certain toxic substances are injected into the blood of pregnant rabbits a deterioration of the eyes of the offspring sets in, which is transmitted and increased generation after generation.

Now examine the other side of the shield. Let us use a little of the evidence from associated sciences which zoologists and botanists have ignored. It has been said by naturalists that man is a domesticated animal, meaning, probably, that man is a social animal like ants and bees. Man is a typical wild animal, living under an enormous variety of conditions, which have become perfectly natural to him. At any rate, he is not under artificial selection. Again, it has been said by opponents of Darwin that no one has seen natural selection in operation, and that, therefore, its existence is a pure guess; and by yet others, supporters of Darwin, that man has escaped from selection. As a fact, every man, except the biologist as such, has seen natural selection in full blast, and, so far from having escaped from selection, man is everywhere stringently selected in a glaringly obvious way. Indeed, since we are able to follow the career of men with a completeness that is unique in the animal world, man is the only animal in which natural selection can be observed and its consequences traced to the last little detail. Apart from each man's personal experience and a voluminous literature, it is the principal function of all Departments of Public Health to collect precise statistical information bearing on this very subject.

Man is the prey of a multitude of living microbic species, which have become parasitic on him, and attack him in all sorts of ways and with every degree of stringency of selection. It is common knowledge that men vary in their powers of resisting various microbic diseases, and that these powers of resistance tend to "run in families" (*i.e.* are inheritable), as is conspicuously the case in tuberculosis—a fact which is still better observable when we compare men of different races; for example, West African negroes and Englishmen in respect to tuberculosis and malaria. Again, it is common knowledge that powers of resisting any disease do not necessarily imply powers of resisting another disease.

Here, then, is natural selection indubitably manifest in the only wild species in which observation of its operations is possible. What is the effect on races? Does any change result? If so, does it accord with Lamarckian or Darwinian doctrine? It may be laid down as a rule to which there is no exception that *every human race is resistant to every prevalent and lethal human disease in proportion to the length and severity of its past experience of that disease.* Here, then, is evolution indubitably manifest as a consequence of natural selection.

But this recital gives no conception of the fidelity with which evolution follows selection. Not only does selection by any disease cause evolution against itself alone, but there are also two main types of diseases which select in unlike ways and cause extraordinarily unlike racial effects. In one group (*e.g.* measles and smallpox) the microbes flood the victim with toxins, soaking even his germ-cells. He dies; or, reacting against these toxins, recovers within a definite period, the duration of which, speaking generally, varies with the abundance and virulence of the toxins. Recovery implies "acquired" immunity, which is often of lifelong duration, and is simply a "use-acquirement"—a response to functional activity. The individual has become "used to," or trained by, the toxins through some physiological process, just as he becomes used to tobacco, or exertion, or the performance of difficult and complex thinking. Practically everyone is susceptible to this class of disease. As a rule, therefore, the survivors are not those who resist illness, but those who recover from it. In the other group (*e.g.* tuberculosis and leprosy) the microbes retain their poisons within themselves, and the illnesses caused by them are usually prolonged and of indefinite duration. The survivors are, as a rule, not those who recover from illness, but those who resist it, *i.e.* those who are "innately" immune. In this class of disease individuals vary greatly in resisting power. Thus, in tuberculosis, there are those who seem quite immune under the worst conditions, those who fall ill under bad conditions but recover when the conditions are improved, those who die after lingering illness, and those who perish swiftly and, as a rule, in early life. Here there is no "acquired" immunity; whoever is infected suffers nothing but injury.

Plainly in disease we have on a vast scale just those "physiological experiments directly involving the complex metabolism of the body" concerning which Prof. Dendy is so hopeful. If the Lamarckian doctrine be true, diseases of the measles type should, by the "transmission of acquired immunity," render the race less and less susceptible to infection until it acquires "innate" immunity; on the other hand, diseases of the tuberculosis type should enfeeble the race by the accumulation of injury until at last it perished. But nothing of this has happened. On the contrary, racial changes have followed precisely contrary lines, those of natural selection. Thus Englishmen who have long been exposed to measles are fully as susceptible to infection as Polynesians, but recover from illness more easily and frequently; whereas races which have long been exposed to tuberculosis (*e.g.* Jews) resist infection much more stoutly than those that have been less exposed (*e.g.* American Indians). The diseases of animals and plants (*e.g.* in the fly districts of Africa) tell the same story, but here natural selection cannot be as closely studied as in the case of man. We see only the consequent evolution. Now compare as to volume and duration the minutely studied and easily observed physiological experiments of Nature which Prof. Dendy ignores with those to which he pins his faith. Obviously, if anyone did establish that the injection of a toxin caused hereditary degeneration, he would discover, not a rule, but one of the rarest exceptions in Nature.

In order to demonstrate the importance of disease selection, it is worth while to pursue this subject a little further. Doubtless there have been many great human migrations, but two especially are recorded in history—that immense surge of Eastern people which established in their present sites many of the modern races of Europe, and that still vaster overflow which carried the inhabitants of modern Europe to the Western hemisphere. If history teaches any lesson with clearness, it teaches this—that unless

conquered peoples are exterminated they invariably absorb or expel the conquerors. Hence the disappearance of the Greek, Roman, Saracenic, Norman, and Turkish governments.

All, or nearly all, human microbic diseases appear to have originated in the Eastern hemisphere, where men first multiplied sufficiently to provide a constant supply of nutriment to the parasites. Myth and history tell first of epidemics. Such diseases as measles suddenly appeared, attacked young and old, and then, having exhausted the food supply, passed to neighbouring populations, leaving behind a human remnant which had acquired immunity. Later, when populations became more dense, the multitudes of new births furnished a perennial supply of food, and enabled many of these diseases (*e.g.* measles and whooping-cough) to become endemic. Epidemic disease, especially if occurring at rare intervals, is always the more terrible; for the old as well as the young are affected, and in consequence the sick are left untended, business is neglected, and famine follows. Many perish who would otherwise have survived. Witness in modern times the fate of many Pacific Islanders. Endemic disease selects more stringently, but more cleanly; the old who have acquired immunity tend the young, and only the less resistant die. Some maladies, especially those which are insect-borne (*e.g.* malaria), are confined to localities, but most others are, in varying degrees, "crowd" diseases. Thus in England no one escapes frequent contact with measles and tuberculosis, which cause illness unless the individual be immune, and death unless he be resistant. All such diseases tend to become endemic as the crowd thickens. We speak of the deadly climate of West Africa; but that of England is even more deadly to visitors from thinly scattered tribes (*e.g.* nearly all savages). There is no evidence that any human race is mentally unfitted for civilisation, but there is the clearest evidence that, physically, only those races are capable of it which have evolved in response to that slowly increasing stringency of selection which occurs when populations gradually become more dense.

Of old the sword exterminated the conquered and dug deep the foundations of permanent empires. With advancing civilisation and the cessation of deliberate extermination, it lost its power. But when Columbus ended the long separation between East and West he bore weapons more deadly than the sword. Except malaria he met no considerable diseases, but the microbes of the East found virgin soil. Thereupon commenced the greatest event and tragedy in human history. The races of one half of the world began to replace those of the other half. As in the ancient Eastern world, measles, small-pox, and other diseases of definite duration swept the continent in vast epidemics. They left behind them an immune remnant. But tuberculosis, endemic from the first, owing to its long duration in the individual, exterminated wherever the conditions favoured its spread. Spain and Portugal, then powerful maritime States, and first in the field, elbowed the weaker British and French into the seemingly inhospitable North. But, while the tropics were defended by malaria, nothing protected the North, where British and French settlers poured into the vast void created by imported diseases. The former won the battle of Quebec. French immigration ceased, and all North America fell into the grasp of the Anglo-Saxon. Later the microbes created, and the Anglo-Saxons are now filling, another void in Australasia. Thus our race won a place in the sun, and to-day has more room for expansion than any other race. In actual truth, even if soldiers, sailors, and settlers founded the British Empire, it was the microbes that established it on enduring foundations. Germany began her war a century too late. If history repeats itself, the Anglo-Saxons are sure to lose their Eastern conquests, where every European settlement is surrounded by a flourishing native quarter; but seemingly they are rooted for ever in the West, where the natives can exist only in the wilds. Every travelling disease has reached almost its limits, and therefore diseases, like the sword, are losing their power of founding permanent empires. The period of the great human migrations is drawing to an end.

The story of the evolution against narcotics is similar. For example, individuals differ greatly in their degree of susceptibility to the charm of alcohol. Some men swiftly acquire an intense craving for deep indulgence in it; but most of us are temperate without effort or very little effort. In other words, we have no great susceptibility. Speaking generally, moderate drinkers are not those who resist temptation, but those who are not greatly tempted. Habitual heavy drinkers are always much tempted. Alcohol is a poison which especially affects the habitual heavy drinker, not only killing the worst cases, but also making many more susceptible to numerous ills—for instance, tuberculosis. Every race (*e.g.* Jew, Greek, Italian, South German, South French, Spanish, Portuguese, West African) which is now temperate in the presence of abundant supplies of alcohol was anciently drunken. That is, every race is insusceptible to the charm of alcohol in proportion to the length and severity of its past experience of it. Precisely the same is true of opium. Natives of India take it in moderation; the Chinese in greater excess, but in less excess than formerly; while Burmans and Australian blacks indulge immoderately and perish swiftly. Nature's unfailing plan of temperance reform is to remove the heavy drinker. The human plan is to remove drink and leave the potential drinker to multiply. But yeast and sugar cannot be eliminated, and human, unlike natural, laws are sometimes disobeyed, and are never immutable.

I have tried to sketch a little of the natural history of man, concerning which so little has been written, but which, even politically, is so much more important than his voluminously described political history. The evidence, none of which I think is disputable, is derived mainly from medical and historical sources, but the problems which arise are biological. They are too big for doctors and historians, who are mere specialists. Meanwhile what has biology done to establish the actuality of natural selection? She has measured some frozen sparrows, she has suffocated some crabs, and she is now conducting some "physiological experiments" to ascertain whether "acquired" characters are "transmissible." Some of her eminent professors have declared that natural selection is a myth, and the pulpits of the contemners of science are filled with acclamations.

But it is mind which presents biology with the greatest of her problems, tasks, and opportunities. Man is the educable animal. On the mental training of his young depends the intellectual status of the individual and the social status of the community. Men of science, especially biologists, frequently urge scientific education. What is it? It implies, I conceive, the supplying of information which is likely to be useful, intellectually or materially, in such a manner that the pupil is left a skilful, unbiassed thinker with an open, receptive, reflective habit of mind. So far as possible he is taught, not what to think, but *how* to think. In the opposite type of education an endeavour is made to close the mind—to bias, to stupefy, to induce an artificial incapacity to profit from fresh experience, to hold beliefs even in the face of conclusive evidence; in brief, to teach the pupil *what* to think, not how

to think. Compare, as products of these opposite types of mental training, Darwin and Huxley with devout Mohammedan and Hindu ecclesiastics. The evidence in favour of scientific education is enormous, decisive, indisputable, but it lies outside the sphere of botany and zoology, in psychology and history. By whatever rational standards we judge human communities—material or intellectual progress, efficiency in peace and war, wealth, enterprise, energy, the production of great thinkers and men of action, civil war, brigandage, murder and other crimes, and so on—we find invariably that the societies the mental training of which has most nearly approached the scientific ideal are the superior. Compare the results of the mental training given by Socrates and his fellows to the ancient Greeks with that given by the Russian popes to their victims. Many nations (*e.g.* the Romans) have fallen because a change for the worse in mental training left descendants too inefficient to preserve that which better-trained ancestors had secured. Many nations (*e.g.* after the Reformation) have arisen because improved mental training enabled them to surpass competitors. Consider the late war and how completely the more biassed peoples have been smashed. But this is a subject too vast for present consideration; I have tried to deal with it elsewhere.[1]

I may be right or wrong as to the conclusions I have reached, but clearly the evidence and problems I have instanced exist. Clearly they are matters for biology, although they have been neglected by her.

Academic biology is of little account in the world. The hobby of some naturalists who use not a tittle of the evidence available, she possesses next to no established truth. Her few students are engaged in unending disputes, all of which are consequent on a misuse of words or a neglect of crucial testing. Her indefensible terminology separates her from a host of subsidiary sciences. But a biology clarified and simplified by a precise terminology, and in possession of a classification of characters similar to that employed in other studies, might easily become the queen of sciences. A few wide generalisations accepted by everyone would then replace the present chaos of opinions, and provide a basis for work of practical utility. The use of evidence from other studies would make their students her own. So strengthened, she would become a power in the land, and perhaps lay the foundations of that golden age of science and human wisdom and well-being of which we all dream.

Surely there are biologists who perceive that the failure to establish truth can have no cause other than lack of right scientific method, and who are prepared to substitute the method of discussion which has created other sciences for that of controversy which has wrecked biology.

G. ARCHDALL REID.

Magnetic Double Refraction of Smokes.

THE interesting discovery recorded by Sig. Tieri in NATURE of August 18, p. 778, that the fumes from an iron arc can, when subjected to the action of a magnetic field, rotate the plane of polarised light, is in close accord with the view of the structure of such fumes advanced by Prof. Elihu Thomson in his recent letters to NATURE, and agrees also with the observation of Mr. Speakman and myself (see NATURE, June 23, p. 520; and July 14, p. 619).

Prof. Thomson explains the sudden enhanced luminosity of the light scattered by the iron oxide smoke when the magnetic field is applied by the particles arranging themselves along the lines of force. For this structure to be effective the particles cannot be spherical, but must consist of rods or chains, for only then would the intensity of the reflected or scattered light vary with "end on" or "length on" incidence. This was confirmed by a microscopic examination of the iron oxide fume, which showed the particles to consist of short strings or chains of roundish beads not touching one another.

The experience of Mr. Speakman and myself is that the fumes from metallic arcs in air undergo rapid changes with time. The minute particles produced at first by condensation of vapour aggregate together to form complexes, which often show a definite chain-like structure when examined after deposition on a slide, but in the air are continually altering their form under molecular bombardment.

Now it seems likely that if by magnetic or electric forces the small chains or strings can be made to space themselves with their axes all in one direction, not only will the effect described by Prof. Thomson be produced, but a beam of polarised light traversing the fume at right angles to the field of force would suffer rotation provided that the plane of polarisation is neither parallel nor at right angles to the longer axes of the small chains. This is just what Sig. Tieri finds, and it might be expected further, if the above explanation is the correct one, that the magnetic double refraction would vary with the age of the smoke and its method of production. The bluish-coloured smoke found by Prof. Thomson to accompany the yellow fumes from the iron arc, and which did not exhibit the magneto-optical effect, consisted probably of single particles, and would be unlikely to show magnetic double refraction. It corresponds with the initial stage of the oxide clouds we have studied before agglomeration has had time to occur.

This striking behaviour of iron oxide dispersed in air discovered by Sig. Tieri exhibits a close parallel to the behaviour of the same substance dispersed in water. Cotton and Mouton and others have investigated the magnetic double refraction of iron oxide hydrosol, and they ascribe the effect to the orientation of rod-shaped or lamellar ultramicrons. Further, the magnitude of the effect was found to increase as the colloid became coarser.

A continuation of the work commenced by Sig. Tieri may well lead to much interesting information on the form of the particles in smokes.

R. WHYTLAW-GRAY.

Eton College, Windsor, August 21.

The Contractile Vacuole.

IN connection with previous correspondence on the mode of production of the contractile vacuole in Protozoa (NATURE, vol. cvi., pp. 343, 376, 441), I find that it is, in point of fact, Prof. Marcus Hartog to whom the credit of the osmotic view is to be given. In a communication to the British Association in 1888 (Rep., p. 714) this observer pointed out that, owing to the semi-permeable surface membrane, substances in solution in the protoplasm of these organisms must attract water, which accumulates at a particular spot until it reaches the surface, breaks through the membrane, and escapes. The membrane spontaneously closes up as the distension is relieved. Prof. Hartog shows that if substances such as sugar or potassium nitrate are dissolved in the outer water to a sufficient osmotic concentration, the production of the vacuole ceases. The paper was reprinted in Ann. Mag. Nat. Hist., Sec. 6, vol. iii., p. 64 (1889). The theory was worked out in more detail by Degen (*Bot. Zeit.*, vol. lxiii., abt. 1, 1905), and is explained by Prof. Hartog in his article on Protozoa in the Cambridge Natural History (1906),

p. 15. My knowledge of Stempell's paper was derived from an abstract in which the osmotic aspect was chiefly emphasised. On reference to the original I find that this part of the process is obscured by a number of complicated subsidiary hypotheses. W. M. Bayliss.

University College, London.

A Correction.

Some months ago Sir Ray Lankester was good enough to write to me in regard to the statement in my "System of Animate Nature" (1920) that he had spoken of evolution as "a chapter of accidents." He asked me to verify the quotation, and I thought I had only to turn to my book-shelves for a minute to find the passage. But in spite of some months of very agreeable and profitable re-reading of Sir Ray Lankester's writings, I have *failed* to verify the quotation, and the only thing to do is to apologise. Perhaps I should have seen that the phrase I ascribed to Sir Ray Lankester was inconsistent with such sentences as these:—"Thus then it appears that the conclusion that Man is a part of Nature is by no means equivalent to asserting that he has originated by 'blind chance'; it is, in fact, a specific assertion that he is the predestined outcome of an orderly, and to a large extent 'perceptible,' mechanism" ("The Kingdom of Man," p. 9); and "They [the mental qualities which have evolved in Man] justify the view that Man forms a new departure in the gradual unfolding of Nature's predestined scheme" (*op. cit.*, p. 25).

I yield to no one in my appreciation of the services which Sir Ray Lankester has rendered to zoology and biology, and I can only express my regret that in a busy life I made a mistake which amounts to an unintentional misrepresentation.

Wrightson's Hypothesis of Audition.

The hypothesis advanced by the late Sir Thomas Wrightson in his book "An Enquiry into the Analytical Mechanism of the Internal Ear" has, it would seem, received such wide acceptance that the following comments upon it may be of interest.

Wrightson suggested that the appreciation by the ear of the constituent notes in a musical chord is due to the recognition and measurement by the brain of certain time intervals, which occur between the changes in motion of the air when it is transmitting music. In proof of this suggestion Wrightson gives graphic examples. First he takes two simple sine curves representing two musical notes, and from them he obtains a third curve which shows the motion of the air when both notes are sounding together. On this compound curve he marks distances between crests, troughs, and crossing points which are equal to the wave-lengths of the two separate notes.

From the identity of these distances Wrightson concludes that when the observer appreciates the constituent notes in a chord he does so by recognising the existence of these time relationships.

I find, however, that this proof loses its value, since it can be shown by trial that purely arbitrary wave-lengths are also represented in the compound curve as frequently as are those of the notes actually present.

It is scarcely possible, therefore, to accept Wrightson's explanation of the power of analysis possessed by the ear, since, all wave-lengths being equally represented, there is no criterion by which the right notes can be recognised and the arbitrary ones excluded.

This criticism, considered in conjunction with that of Boring and Titchener (*American Journal of Psychology*, vol. xxxi., 1920, pp. 101–13), would seem to take from Wrightson's theory almost all the essential features which individualise it from the older telephone theory of Rutherford. H. Hartridge.

The Generation of Heath-fires.

It is the general practice to attribute the heath-fires which have been so common of late to the careless dropping of matches or to the camp-fires of picnic-parties. But this is not always the cause. An instance came under my notice during the late hot weather which seems to be worth recording. I was walking along one of the ridges at Finchampstead, Berks, and to the south was a fairly steep slope of peaty heath land, giving rise here and there to clumps of bracken, but exposed each day to the sun's rays for many hours at a time. Noticing some smoke emerging from the soil, I turned down the slope to stamp out a possible fire, and I found that as soon as it was put out in one place it emerged elsewhere, a foot or so away. My companion and I repeated the process in many places, but soon we saw that the smoke was emerging from a hundred places, and our efforts were useless. Smoke was rising out of the peaty soil over an area of at least a quarter of a square mile, and another hour of the sun's heat might have been sufficient to result in the place breaking into flame.

From a note in Nature of January 27 last, p. 704, in regard to the spontaneous burning of coal-seams in the United States, I see that the fine dust of lignite may ignite at 150° C., and I suggest that in the case in point the finely divided carbonaceous soil may have been undergoing such changes under the heat of the sun, which may have brought up the temperature to something approaching this. Anyway, here was a considerable area smoking under the intense heat, and ignition could not have been far off. Edwd. A. Martin.

Cornalith.

In the *Bulletin of Agricultural Intelligence* issued by the International Institute of Agriculture, just to hand, there is a précis of an article in the *Annales de Gembloux* under the heading "Plastic Materials with a Casein Basis: Galalith and Cornalith." The latter word is not in the N.E.D. or in the recently published "Dictionary of Scientific Terms." Galalith, or "milk-stone," is well known, and cornalith will be "horn-stone." The first sentence in this précis reads: "Galalith and cornalith, two substances made from casein that has been treated with formalin, are produced now in various countries, especially in France, where there are already several factories."

It is stated that, in order to diminish the cost of opaque articles made from casein treated with formaldehyde, the raw material is sometimes mixed with the refuse of horns, horsehair, and other nitrogenous matter. When this is done is it called "cornalith," and, if so, does the name or term correctly describe the material?

It is also stated that attempts have been made to use vegetable casein extracted from soya beans, as being less expensive than casein obtained from milk. Has this been successfully accomplished, and, if so, can the resulting plastic material be called "galalith," or is some other term used? R. Hedger Wallace.

August 16.

Pulverised Coal as a Combustible.

By SIR R. A. S. REDMAYNE, K.C.B.

COAL, which has, ever since the growth of modern industrialism, proved the main source of artificial heat, power, and light in civilised countries, is likely to continue to occupy that position for very many years to come. In some industries it constitutes the chief item of cost in production; in others it is second only to that of labour. Its importance, therefore, as a factor in the cost of living is very great indeed. That the price of coal, at any rate for a long time, will be maintained beyond a pre-war level cannot, I think, be controverted. The higher wage demands of labour incident to the advance in the standard of comfort claimed are not likely to be so abated as to bring wages down to a pre-war position; for the same reason the cost of the materials so largely used in mining—*e.g.* timber, steel, lubricants, and machinery—will remain at a high rate. The chief hope of securing a reduction in the cost of production must lie along the lines of research. Similarly, also, the reduction in the cost of our fuel bill must be sought in economy in use—that is to say, in an endeavour to use efficiently every calorie available in the fuel.

In this connection the use of coal in the form of dust has for some few years been occupying the attention of engineers, particularly during the last five years, and more especially in North America. In the year 1919 the Fuel Research Board published a brochure on the subject, and the May number of the *Bulletin de la Société d'Encouragement pour l'Industrie Nationale* contains a most interesting article by M. Frion entitled "Le Chauffage au Charbon pulvérisé," being a report of the "Commission d'Utilisation des Combustibles," in which it is stated that "le développement devint assez rapide à partir de cette époque, et actuellement les industries du fer et de l'acier emploient environ 3 à 4 millions de tonnes de charbon pulvérisé par an, et les industries du cuivre un tonnage à peu près égal."

The use of coal in the form of dust for raising steam had, from isolated experiments, been known for the last thirty to forty years, but the fact that it is probably the most difficult method of burning coal delayed the development of the practice until means were discovered of surmounting the obstacles in the way of its use. When it is considered that if a cubic inch of coal which has an exposed surface of six square inches is crushed into cubes each of which has a side one-hundredth of an inch in length, and the exposed surface of the crushed coal becomes 600 square inches, the theoretical advantage of burning crushed coal becomes obvious. A more intimate mixing of the fuel and air is rendered possible, and this without using a large excess of air; for example, with an average boiler furnace fitted with mechanical stoking it is considered good working practice under normal conditions if 150 to 200 per cent. of excess air is being admitted to the furnace; on the other hand, under pulverised-fuel firing there is no difficulty in working regularly with not more than 20 to 30 per cent. of excess air.

One of the difficulties which originally lay in the way of the widespread use of pulverised fuel was the heat engendered in the grinding of the coal to the requisite fineness, sometimes resulting in combustion. Again, inasmuch as coal dust cannot be shovelled into and burnt in an ordinary furnace, special burners had to be provided. However, a number of well-tried and standard methods for both the preparation and the burning of the fuel are now in existence, the underlying principle of all of them being the same, though differing in the design of the various parts of the equipment. The coal is dried, pulverised, and the dust, passing to a furnace, is conveyed to a burner, and then, mixed with air, burnt in the form of a jet. Each system has its own peculiar methods of performing these operations, some systems being more suited to certain conditions than others. A point common to all the systems, however, is that of the fineness to which it is necessary to reduce the coal. It has to be ground so fine that the dust will pass through a 100-mesh screen (*i.e.* a screen containing 10,000 apertures to the square inch), and 85 per cent. through a 200-mesh screen (*i.e.* a screen having 40,000 apertures per square inch). In order to effect this the coal must be dried so as not to contain more than 1 per cent. of uncombined moisture, the dryness being necessary from the point of view of manipulation, as the fuel must be capable of being handled without clogging or sticking in the feeding and burning equipment. In the process of drying, care has to be taken against overheating, which may result in loss of volatile hydrocarbons. The cost of securing a higher degree of fineness than that specified above is not justified by the extent of the increased efficiency obtained. On the other hand, practice has shown that if the degree of fineness is much below the standard named above troubles arise due to deposits of ash and slag and from irregular burning.

The separation of the coal ground to suitable fineness from that which is not of sufficient fineness is effected by screening or by air separation. In the latter method a stream of air at constant velocity carries away from the crushed coal particles of a certain definite size and so secures a uniform product, but the use of an air separator requires upwards of 50 per cent. more power to work it than a screen to perform the same amount of useful work, in addition to which the cost of maintenance of the former is heavier, due to high velocity and excessive strains. With air separators the mixture of air and coal dust is carried to a cyclone dust collector, where the stream of air

entering the larger volume of the collector is deprived of its velocity and the coal dust drops. With the screen separator the coal is elevated by a bucket elevator and conveyed to the furnace by a screw conveyor.

There are a number of different forms of burning the dust in use, the fuel being driven into the fire-box by means of either fans or compressed air. In one system the air pressure is exerted in the tank, which is in connection with the furnace by means of a pipe, and the dust forced in a stream, unmixed with air, through the pipe to the furnace. In another system the coal dust is drawn from the storage bin as required, mixed with air, and carried in suspension through pipes to the furnace at a velocity of 5000 ft. per minute. Mixing air with the coal dust would appear to increase the liability to explosion. In yet another system the dust from the feed worms is blown into the fire-box, the fuel and air passing as a cloud into the fire-box and being ignited by a piece of waste soaked in paraffin.

One economy incidental to the use of pulverised fuel under boilers has already been mentioned—viz. reduction in the amount of fuel as compared with lump coal to secure a given heat result. Other economies may be mentioned, as follows:—

(*a*) Ability to use low-grade coal.
(*b*) Saving in labour of stoking.
(*c*) Flexibility of the operation, coal-dust firing being almost equal in this respect to oil firing.
(*d*) Elimination of "banking" and easier disposal of ashes.
(*e*) Possibility of safely working the boilers at loads largely in excess of their normal rating.
(*f*) Ease of control of furnace conditions in the case of metallurgical furnaces.

Against these advantages, however, must be ranged the cost of preparing and conveying the pulverised fuel and the interest and depreciation on the capital outlay. These are very variable items, dependent, as they are, on local conditions in respect of labour, power, and fuel, but chiefly on the output per day of the plant. For instance, in the United Kingdom, under present conditions, it is not considered a paying proposition to use pulverised fuel in the case of stationary boilers having a lower fuel consumption than 40 tons of coal per diem. On the other hand, with a fuel consumption of 200 to 300 tons per diem a handsome saving can usually be secured by the replacement of lump coal by pulverised fuel under almost any conditions. As a rough guide it may be taken that with almost any of the well-known standard "systems" the cost of preparing, pulverising, and burning in the form of dust 1 ton of coal, will be about 5*s*. in the case of a plant dealing with 100 tons of coal per diem. Of course, the higher the price of the raw fuel the greater the saving by using it in pulverised form.

Pulverised coal has been successfully applied to almost every kind of heating work, with the possible exceptions of open-hearth steel furnaces, steamships, and such furnaces as glass tanks, where contamination of the charge from particles of ash is to be avoided. The first really successful application of dust-coal fuel was in respect of rotary cement kilns, where the conditions are such that the problem of the disposal of the ash does not exist, and a large combustion volume is available with a free, unobstructed passage for the flame. The next step in its application was in the direction of various types of metallurgical furnaces, more particularly reheating, puddling, and similar furnaces, and complete success has been obtained in most cases.

The case of stationary steam boilers of the water-tube type has been found more difficult of treatment. In the early stages of the adaptation of coal dust to firing, considerable trouble was experienced from the ash and the rapid wear of the furnace lining and from imperfect combustion. Experience has shown the way of avoiding these troubles, and it is now a fact that pulverised fuel can with complete and permanent success be applied in raising steam from any type of tube boiler. In the case, however, of the cylindrical internal flue type of boiler—as, for example, the Lancashire boiler—the process of dust firing has not, so far, proved successful under continuous operation; but, seeing that firing with "straight" oil and with "colloidal" fuel has succeeded in this type, there seems no reason why the problem should not in time be solved in respect of coal-dust firing.

Perhaps the most difficult conditions for the successful application of pulverised fuel were those in respect of locomotives, owing to the small combustion area available and the cramped conditions generally; yet recently it has been completely successful, and locomotives equipped with this system of firing are in use in the United States of America. A fact of peculiar importance, as pointing to a means of utilising low-grade fuel, is that on the Brazilian Central Railway some locomotives are being worked with pulverised coal derived from local deposits of inferior quality in place of using high-grade imported lump coal. In England a system for locomotive use has been successfully developed and has been in service for some time with very successful results. Enough has been said to show that the preparation and use of pulverised coal have been brought to a practical and economic stage, and where the conditions are suitable its use constitutes a proposition worthy of the serious attention of large consumers of fuel. To readers who wish to pursue this matter further the perusal is recommended of the report in the *Bulletin* already named, the Report of the Fuel Research Board, and Mr. C. F. Herington's work on "Powdered Coal as a Fuel."

As illustrative of recent developments, two cases may be quoted. One is from the *Bulletin*, in which M. Frion says:—

"Nous ne citerons que l'exemple particulière-

ment démonstratif de l'installation nouvelle de 50,000 chevaux en cours de montage à la Milwaukee Electric Railway and Lighting Co. destinée à alimenter une centrale de 200,000 kw." At home pulverised coal has recently been applied at the Hammersmith Central Electrical Station.

The advent of a new process in connection with coal dust has resulted in a considerable step forward being made towards the reduction in the extent of the equipment necessary in the preparation and conveyance of coal dust for combustion. This process is that by which the finely divided coal dust is intimately mixed with oil to form what is inaccurately termed a "colloidal" fuel, for *colloidal* it is not. In this process the coal is ground in oil, a mixture resulting which is sufficiently stable for all practical purposes, especially so when the proportion of solid fuel contained therein exceeds 50 per cent.; mixtures of equal quantities of oil and coal have been used after standing three months in barrels without any difficulty having been experienced in regard to sediment.

In the case of the so-called "colloidal" fuel, unless the amount of moisture is very excessive, the coal can be used without having to resort to drying preliminary to crushing, which means a curtailment in the equipment required as compared with the use of simple pulverised fuel. It has a further advantage in respect of transportation and of handling, in that it is a semi-liquid, and can be treated as an oil fuel, after due allowance for its greater viscosity. It is not liable to spontaneous combustion, and is burnt in the same manner as if it were "straight" oil.

The field for the use of "colloidal" fuel is great. The fuel can be employed wherever oil is applicable as a steam raiser. Its wide application will result in a vast saving in the consumption of oil, and its manufacture allows of the useful employment of low-grade coals and of coals deficient, for other purposes, in volatile constituents.

Remarks on Gravitational Relativity.[1]

By SIR OLIVER LODGE, F.R.S.

IV.

WHEN we come to the more general theory, which attends to the acceleration and not merely the velocity of the observer, I find myself in disaccord on some points with many eminent exponents, chiefly in connection with their abolition of the idea of "force," and the consequent replacement of gravitation by a modified geometry; as if the earth's natural motion was in a hypocycloidal sort of spiral, and was not under compulsion by any deflecting force.

A revolt against "force" as a real objective entity was led by that great mathematician and physicist, Prof. Tait of Edinburgh. In the first instance he rebelled against the practice, adopted by text-books of the period, of using the term "accelerative force" instead of "acceleration," and making a muddle of the laws of motion by formulating what they called Law 3 thus:—"When pressure communicates motion to a body the accelerative force varies as the ratio of the pressure to the mass." Then he objected to some of the pedagogic arrow-heads sprinkled on mechanical diagrams, especially the arrow-head representing centrifugal force; since it is obvious that no such force acts on the revolving body. Ultimately Tait or his disciples (W. K. Clifford too, if I remember right, also Mach and Kirchhoff) were prepared to abandon the term force altogether, and to substitute space-rate of change of energy, or time-rate of change of momentum, or mass multiplied by acceleration, as a more real equivalent. Tait even denounced the idea of balanced forces, saying that only their effects were balanced ("Ency. Brit.," 9th ed., art. "Mechanics," §§ 285–300); as if two opposing forces were each producing their proper amount of acceleration, or of momentum, but in opposite directions. Though how this kind of statement could include the production of scalar quantities, like work and energy, is not apparent. The whole idea of "cause" came into disrepute.

Now mass-acceleration truly is a measure of the force which produces it, but that does not mean identity. Reformers spoke sometimes as if they meant identity, and desired to get rid of the term force altogether because it had been so misused. After a lecture by Prof. Tait to the British Association on "Force" (at Glasgow, in the year 1876), Sir Frederick Bramwell amusingly said that in the North of Britain the term meant a waterfall, while in London it meant the police, and that really, after the lecture, he himself scarcely knew exactly what it did mean! In that lecture Tait had dealt pugnaciously with some misuses of the term by Prof. Tyndall and other scientific people; for it is not so long ago that the words *vis* and *Kraft* were used with but little modification or caution for the quite different conception of Energy. "The Persistence of Force" was a phrase frequently employed in philosophic writings. Indeed, an accurate nomenclature has scarcely yet penetrated into common usage; and the result is an unnecessary vagueness about the term, typified by Sir F. Bramwell's more than half serious confession. Centrifugal force, for example, can be treated correctly enough by equating it to the product of inertia and rate of change of velocity, but that does not do away with the force: the force is exerted by the revolving body against its constraints. The word is misleading if thought of, in what was no doubt its original intention, as a radial fly-away tendency; it should connote only

[1] Continued from p. 785.

an outward radial pressure, due to kinetic reaction against the normal component of acceleration. It is the necessary correlative of the centripetal force which must be acting on any revolving body. Centrifugal force is not acting on the revolving body, and, strictly speaking, should never be so thought of, or so depicted: it is the pressure or reaction exerted by the body on the groove or rail or æther, or whatever it may be that guides and deflects it.

Part of the mistake, if I may call it so, connected with the denial of physical reality to the directly apprehended thing called force, is the identifying of a thing with its measure. Because two things are equivalent it does not follow that they are identical. There is room for both; and force may be measured statically as well as kinetically. It is only unbalanced force that produces acceleration and calls out kinetic reaction. Acceleration is often prevented by an equal opposite force, but that does not abolish the force. Whether balanced or unbalanced, force is real enough. If Galileo had been put on the rack, the assurance of an Inquisitor that he was only suffering from balanced accelerations would have been no relief. It will be said that force is only one end of a stress, and that attention to the stress is the illuminating thing. That is perfectly true; but as a fact of experience we came across force before we understood about stress, and there are states of stress which we still are not able to understand, because they occur in the æther, and only display themselves by their "ends"—that is, by the pair of equal opposite forces in which they terminate—called in old phrase "action and reaction."

The weight of a book, or a stone, or an apple is a force acting on it; this force is due no doubt in the last resort to a stress in the ætheric medium, but we experience it as a force when we resist it muscularly; and though we may measure it by the mass-acceleration of the body when allowed to drop, it acts equally when the body is resting on a table or hanging from a twig; only then the reasoned and hypothetical æther stress is counteracted by an obvious stress in the material support. The stress can be measured by resting the body on a spring, or hanging it from a piece of elastic; and the strain so caused is surely an undoubted reality, about which it would be extremely artificial and confusing to postulate any kind of acceleration. Some day we may be able to dive into deeper constitutional secrets, and explain all stresses and strains kinetically in terms of the gyrostatic rigidity and elasticity of æther; but that time is not yet. Meanwhile the objects here used in illustration are in static equilibrium, are obeying the first law of motion and moving with uniform velocity, so long as the forces acting on them are equal and opposite and therefore balanced.

But an unbalanced force can always be equated to the kinetic reaction or mass-acceleration of the body acted on; and in dynamics unbalanced forces are those which demand attention. All the rest is the statics of strain. D'Alembert's principle rather tended to tempt us to contemplate spurious forces, for supposed convenience, so as to reduce kinetics to statics when writing down equations—for there must be equilibrium among the internal forces acting within the confines of any closed system—and a flagrant elementary example of the kind of thing thus led up to was the ordinary text-book treatment of centrifugal force.

Elementary Repetition.

If a governor ball or conical pendulum is depicted on paper, the only arrows that ought to be drawn on it are those representing the tension in the string and the weight of the body. But such a diagram looks unfinished; nothing could rest like that; the two forces are evidently not in equilibrium; they clearly have a resultant. The unpardonable, or at least the confusing, thing is for a teacher to draw an arrow indicating a force equal and opposite to that resultant in order to make the diagram look comfortable and static. The fact is that no third force acts on the body; the body itself reacts, its mass-acceleration is equal to the resultant force; and that is the proper fact to express in an equation; you cannot express it in a diagram. The diagram can be completed only by motion, and it ought not to look as if equilibrium were attained by any part of the system. The system as a whole is in equilibrium, or the internal stresses balance, directly the kinetic reaction is taken into account, not otherwise. Centrifugal force, as the term is often employed to signify a force acting on the revolving body, is a fiction.

Yet centrifugal force is a reality; it is essential to the equality of action and reaction. There ought to be no objection to the term or idea when properly applied. But it does not act on the revolving body at all. In every instance the real centrifugal force acts, not on the revolving body, but on whatever fixed centre is responsible for holding it in its orbit; or on the constraint, such as rails or groove or ætherial medium, which is directly effective in guiding and deflecting it. The centrifugal force of the moon acts, not on the moon, but on the earth. It is part of the cause of the tides. No doubt it is primarily exerted on the ætherial medium in contact with each lunar particle, and is thus transmitted to the earth at the other end of the gravitational stress.

To finish this trivial pedagogic discussion of centrifugal force in its true, as distinguished from its usual artificial, sense, and the confusion about which body the force really acts on, we may as well point out that the same sort of trifling difficulty—caused by there being always two bodies bounding a stress,[2] while we are liable to concentrate attention on one—is responsible for that simple old puzzle about the horse and the cart. If the cart pulls back as hard as the horse pulls forward, why does it move? Every good student, sooner or later, asks himself or his teacher this question. The correspondence columns of the *Engineer* at one time exhibited persistent misconception about this elementary matter among quite a large number of readers, and some text-book writers have been bothered by it. The confusion is caused entirely by the tacit assumption that both forces must act on the cart. Not so; one acts on the cart and one on the horse. Two forces and two bodies, one force acting on each. The difficulty disappears. The horse must get a grip of the ground to enable him to exert his force on the cart, true; and the cart exerts its reaction on the horse entirely be-

[2] The fact that an advancing wave-front may simulate a body, for this purpose, is of high interest.

cause of, and in proportion to, its mass-acceleration, until friction and other obvious extras have to be taken into account.

The Principle of Equivalence.

In returning from this, I hope pardonable, elementary digression to more general considerations, let me quote and amplify a sentence from a sort of summary which will appear in the *Fortnightly Review* for September:—

> To ignore or deny or supersede the gravitational stress, merely because we do not yet understand the particular configuration of the æther which is responsible for it and which renders it possible, is to blind our eyes dangerously to dynamical reality, and to rest satisfied with a mere geometrical specification of the motion as if it were a peculiarity of space.

The "principle of equivalence" formulated by Einstein claims that the inertia reaction of a revolving body, to the centripetal force responsible for the curvature of its path, is of the same character as what we call the force of gravity, due to the neighbourhood of a large mass; that this inertia reaction is indistinguishable from weight; and, generally, that no distinction can be drawn between an artificial field of force, such as that representing the effect of a carefully defined revolution round a centre, and what we are accustomed to think of as a real field of force, such as that surrounding the earth.

We are told that by referring motion to rotating axes it is possible to abolish revolution and to replace it by a centrifugal force acting outwards on the body, thereby enabling the body to be treated as if in static equilibrium. We do this when we draw a static diagram of a revolving body, say a conical pendulum or pair of governor balls, and when a spurious and non-existent force is supplied, to represent the inertia reaction, and to balance the centripetal-force component which in reality is curving the path. I called this "unpardonable" in an elementary text-book, and also wrong as a philosophic representation of fact, but as a mathematical device it seems to be permissible; at any rate, it is quite consistent with the principle of relativity. In fact, it is part of the foundation of Einstein's principle of equivalence.

Now it is true that the most careful experimentation (first Newton, and now Eötvös) has shown that weight and inertia are accurately proportional. So it is possible to balance weight precisely by inertia reaction, and, for calculation purposes, to treat centrifugal force as if it were an artificial kind of gravity, obedient to the same laws. But this can only be done with due caution and limitation, for it does not represent reality, and the laws are not in all respects the same.

We are also told that, by choosing accelerated axes as our frame of reference, weight can be abolished too. Passengers in an unsupported, and therefore freely falling, enclosure, such as a cage or lift, would experience no force of gravity; for nothing would require any support, and nothing would tend to move out of its place as defined by the walls of the room, which constitutes the passenger's natural frame of reference.

We are told still further that the behaviour of things inside an enclosure or cage in free space, dragged along by a hook with an acceleration of 32 ft. per sec. per sec., would be indistinguishable from the behaviour of things inside a stationary or equilibrated cage slung by the same hook above the earth. These examples are instructive, for in many respects the behaviour would be just the same. But such illustrations must not be pressed to philosophic extremes, as if there were really no discrimination. For one of the two cages, after the lapse of about a year, would attain the velocity of light; and surely something noticeable must happen then, even if only the invisibility of the floor. Moreover, force is not really evaded; for *something* must be dragging at the hook—something quite gratuitous—whereas the influence of the neighbourhood of the earth is a manifest *vera causa,* however little we may as yet understand about its ætherial mechanism. It must not be supposed that we have no criterion for what is *true* in all these cases; we need not allow that we have no means of discrimination, and that we are really subject to all the uncertainties and ignorances about absolute truth which tend to be grafted on to us by the doctrine of relativity in general and by the principle of equivalence in particular.

The fact is that the passengers-in-a-lift argument, like others that we encounter round about this subject, is of very limited application. It can be well used to illustrate certain non-obvious and interesting facts, but innumerable considerations contradict the idea that the force of gravity is really nothing else than a fanciful name for the mass-acceleration which can be written in equations as equivalent to it. After all, distinction is quite feasible between the reaction of a heavy body on the earth to its centripetal diurnal acceleration, and any corresponding fraction of the force of gravitation. The two do not even act in the same direction, save at the equator; and at the poles one vanishes. What is true is that the resultant between the pressure of the ground on a stone or man, and the real weight of the stone or man, is an unbalanced force which causes that stone or man to rotate round the earth once a day, and (if we allow for complete weight) round the sun once a year. Attachment to the earth has nothing to do with astronomical motions of our human body; for we are not attached. Each of us, and each loose pebble, is as much a planet as the earth, and nearly as much a satellite as the moon.

To say—if anyone does—that the force exerted by a gravitational field, such as might be due to a heavy mass at the centre of a wheel, is indistinguishable from any other constraint needed to curb the inertia reaction of a particle attached to the rim of the wheel when it is revolving, is false. For the way the force is applied is not the same, and the law of force is different. The one increases with distance from centre, the other diminishes with the inverse square.

To reduce the field of the earth locally to zero by means of a falling elevator or "lift" is feasible for observers inside the lift, so long as it is small. But if, in an extensive falling chamber, gravity is to be imitated or neutralised exactly, its parts must fall in different directions, or with different accelerations, or both.

The elimination or avoidance of the idea of absolute rotation, through imitating or replacing centrifugal reaction by the influence of the stars, or by an imaginary distribution of attracting matter in distant space, round the earth or other rotating body, is preposterous, and cannot be seriously contemplated.

I know that the mathematical physicists who allow themselves to assist their exposition by employing illustrations of this kind must be well aware of the limitations attending their use; but I do not think that philosophers always are, and they may not always attend to the cautionary language employed by careful expounders. In fact, the so-called "principle of equivalence," like other popular wordings of extreme relativity, is liable to lead an incautious exponent to go beyond what is legitimate or necessary, and to land him in paradox. Yet if not pushed to absurd extremes, and if the wording is carefully guarded, the principle of equivalence is useful enough; for it is true that any effect on bodies produced by their weight can be imitated by whirling them on a revolving table. Mechanically the principle is used in industrial separators of various kinds, and in any operation requiring an enhanced value of gravity; and the principle extends to optic and electric effects also.

Reference to Mercury's Orbit again.

The theory of relativity, though originally suggested by electrical theory, was developed without further reference to that theory, and reduces an orbit to a mere spatial relation determined by the central body. But it should be clear that, unless an æther is admitted, the gravitational potential or potentials essential to the theory must represent an action-at-a-distance of the central body on space. In the third article (NATURE, August 18, p. 784), when discussing the orbit of Mercury, I did not seek to explain how it was that an extra small perturbation was necessitated by the principle of relativity; because no question about it has arisen, and because it has been done, so far as reasonably possible, at least for the bending of light, by Prof. Eddington, in chap. vi. of his book "Space, Time, etc."; while the equations are in chap. v. of his "Report" to the Physical Society of London; or, in another form, in Cunningham's "Relativity," second edition. The theory for a planetary orbit is similar to the light-path theory; but it is difficult to put the gist of it into ordinary language. Suffice it to say (1) that Newton showed, in the "Principia" (Book I., sect. ix.), that the inverse square law is the only one to give an exact elliptic orbit, and that the slightest interference with that law would bring about a specified revolution of the orbit in its own plane, *i.e.* an apsidal progression; or, in vaguer words, would prevent the same orbit from being retraced or repeated by the planet. And (2) that the Relativity theory, virtually though not explicitly, does interfere with the exact law of inverse square, especially for a near planet. For in the ordinary equation for orbital revolution in general,

$$\frac{d^2}{d\theta^2}\left(\frac{1}{r}\right)+\frac{1}{r}=\frac{Pr^2}{h^2}$$

(with P as the acceleration at distance r from the central body M, and $\frac{1}{2}h$ as the constant rate of sweeping areas), the right-hand side is constant only for an inverse square law, $P=GM/r^2$. But relativity adds to the right-hand side, which ordinarily would be GM/h^2, another term, namely $3GM/c^2r^2$; and this small term is the one responsible for the departure from an exact conic-section orbit. The discrepancy thus introduced turns out to be right for Mercury, and insignificant for other planets; while it does not interfere with their eccentricities. Moreover, the same term is responsible for the bending of a ray of light. So the double success is very striking, and the jubilation entirely justified.

To sum up this portion.

Force is essentially a human conception derived from our muscular sense; and, from the psychological point of view, is as basic as motion, and more directly apprehended than matter. Unforced motion is straight and uniform,[3] not varying or curvilinear, and acceleration is not a fundamental property of matter, nor a diversion of empty space, but is always the result of pressure exerted upon a mass by other bodies, or in the last resort by the circumambient medium.

To geometrise physics, even if legitimate for convenience of calculation, is ultimately to complicate it. Directly the operation becomes complicated it becomes needless, or even obstructive. The new facts can be accepted, and the relativity equations can be used, but a physical explanation can still be looked for, and our knowledge of the universe will not be complete until it is found. We cannot be for ever satisfied with a blindfold mathematical method of arriving at results. We can utilise the clues so given, and admire the ingenuity which has provided them, but that is not the end; it is only the beginning. The explanation is still to seek, and when we really know the properties of the æther we shall perceive why it is that things happen as they do.

CONCLUSION.

The relativity method, by aid of its differential geometrical analysis, seeks to interpret all that is directly experienced through our senses as a manifestation of the peculiarities of space. Matter and all its functions are thus reduced to a kind of subjective space-time geometry, and everything absolute has disappeared from the physical world.

An alternative view of what may be the outcome

[3] Straightness means that no reason for deflection in any direction can be assigned; and the absence of any accelerating or retarding cause yields uniformity.

of the method—a view taken in these articles, though it is not likely to be immediately acceptable to fully assured relativists—is to regard the theory of relativity as an indirect attempt, not unlike the principle of Least Action, to treat all material phenomena as developments or manifestations of unknown essential features in one universal medium; thus restoring a kind of absoluteness to motion, and therefore presumably to space and time. From that point of view the comprehensive scope of the method, with its infinitesimal continuity of treatment, is hopeful and encouraging; and the highly abstract and symbolic modes of representation, which now seem inevitable in its more advanced developments, are the tribute to our ignorance of the kind of dynamics appropriate to a substance the properties of which must be more fundamental than any we are likely as yet to have encountered among its sensory derivatives, electricity and matter.

The Edinburgh Meeting of the British Association.

By Prof. J. H. Ashworth, F.R.S.

Programme of the Sections.

The Journal for the Edinburgh meeting of the British Association, now in the hands of the printers, shows the completed plans for the business of the various sections. In particular, attention may be directed to the careful arrangements for the joint discussions. "The Age of the Earth" is to be the subject of a discussion, by the conjoined sections of physics, geology, zoology, and botany, to take place in the Natural History Lecture Theatre, Old College—the largest theatre in the University, with accommodation for an audience of more than 400. The discussion will be opened by Lord Rayleigh, and other speakers will be Prof. Sollas, Prof. Eddington, Prof. J. W. Gregory, and Prof. Lindemann.

Sections A and B will take part in a discussion on the structure of molecules, to be opened by Dr. Langmuir, of New York. He will be followed by Prof. Smithells, Prof. W. L. Bragg, Prof. Partington, Prof. Rankine, and others.

Chemists and physiologists will find common ground in the discussion on "Oxidations and Oxidative Mechanisms in Living Organisms," to which Prof. Gowland Hopkins will contribute the opening paper.

The sections on geology and engineering are to discuss the various aspects of the proposed mid-Scotland canal. The geology of the suggested route will be explained by Mr. M. Macgregor and Mr. C. H. Dinham, of H.M. Geological Survey.

"The Origin of the Scottish People" is to be the subject of discussion opened by Sir Arthur Keith before the joint sections of geography and anthropology. Prof. T. H. Bryce, Lord Abercromby, Prof. R. Weymouth Reid, Prof. Jehu, Prof. W. J. Watson, and Dr. Tocher are to take part in this discussion.

The sections of geography and education will combine for discussion on the teaching of geography, which will be opened by Mr. G. G. Chisholm, and it is hoped that Sir Richard Gregory, Sir Halford Mackinder, Prof. J. W. Gregory, Prof. Patrick Geddes, Dr. Rudmose Brown, Mr. W. H. Barker, Mr. T. S. Muir, and others will put forward their views on this subject.

The sections of zoology and psychology are to discuss "Instinctive Behaviour." Dr. Drever will open for the psychologists, and he will be followed by Prof. Goodrich, Prof. J. Arthur Thomson, and others.

A joint meeting of the sections of economics, psychology, and education will be held to discuss "Vocational Training and Tests."

The discussion following the presidential address in Section K, in which Section C is to take part, on the early history of plants, with special reference to the Rhynie fossil plants, promises to be an outstanding feature. These plants, representative of the earliest known land flora, had an organisation different from that of any living land plants, and their investigation by Dr. Kidston and Prof. Lang has thrown much light on the evolution of land floras. In addition to the president of Section K (Dr. D. H. Scott), Dr. Kidston, Prof. Lang, Dr. Horne, Prof. Bower, and Dr. Lotsy will take part in the discussion. There is to be an extensive demonstration by Dr. Kidston in the Botanical Laboratory, Royal Botanic Garden, of sections of these Rhynie plants.

As indicated in a previous notice, the presidential addresses in other sections are to be followed by discussions, and in several cases should lead to interesting debates, for instance, on "The Principles by which Wages are Determined," on "The Place of Music in a Liberal Education," and (at the Conference of Delegates of Corresponding Societies) on "Science and Citizenship."

There are other discussions planned which, though nominally forming part of the programme of one section only, will attract interested members from other sections. Among these may be mentioned discussions on "An Imperial School of Anthropology for the Training of Civil Servants and Administrators in the Dependencies of the Empire," on "Heavy Muscular Work," on "Size and Form," on "Extramural Education," and on "University Reform."

There are to be, as usual, many communications giving the results of recent investigations, and there will be exhibitions of apparatus and specimens and demonstrations of methods.

Nearly all the sections have arranged excursions to places of special interest to their members. The local secretaries of the sections of chemistry, geology, engineering, and botany have been par-

ticularly active and fortunate in their arrangements. These excursions are necessarily limited in number, and only those really interested are expected to join them. The arrangements for these are in the hands of the respective sectional secretaries. There are in addition eighteen excursions open to all members. Information regarding these is given in the local programme, and further details can be obtained at the excursions counter in the reception room. The Excursions Committee has succeeded in making arrangements for members, up to the number of two hundred, to visit Loch Lomond, Loch Katrine, and the Trossachs by motor charabanc and boat, and for a further two hundred to visit the Scott country—Melrose, Dryburgh, Abbotsford, and the Valley of the Tweed—by motor coach. Early application for these excursions is desirable. It is hoped that full advantage will be taken of arrangements which have been made for small parties, not exceeding fifty in each group, to visit Old Edinburgh under the guidance of experts, each visit to extend over two afternoons. Members who will arrive in Edinburgh on Tuesday or early on Wednesday. and are interested in the Old Town, are advised to join one of the four parties which will set out on the Wednesday afternoon at 2.30. These will complete the inspection of the Old Town on the Thursday afternoon. Another party will start on Thursday afternoon and finish on Friday afternoon, and a third party will begin on Monday afternoon and finish on Tuesday afternoon.

There is to be a special graduation ceremonial in the McEwan Hall on Tuesday, September 13, at 3 p.m., at which honorary degrees in the faculty of law will be conferred. Members of the Association who propose to attend the ceremonial in academic dress are desired to hand in their names at the general inquiries counter in the reception room on or before the morning of Monday, September 12. The secretary of the University has kindly arranged to reserve seats for them and to include them in the academic procession.

Members who are golfers will be glad to hear that several of the well-known Edinburgh clubs have been good enough to intimate that a number of members of the Association will be made honorary members of the clubs for the period of the meeting. The local secretaries will be pleased to give particulars.

Obituary.

Prof. Edmond Perrier.

PROF. JEAN OCTAVE EDMOND PERRIER, the announcement of whose death appeared in NATURE for August 4, p. 721, had been, for longer than many of us can remember, one of the most distinguished of contemporary French zoologists. Born in 1844 at Tulle (Corrèze), he entered the Ecole Normale Supérieure in 1864, and for some years devoted himself to mathematical and physical studies; but he was a born naturalist, and the call of the natural sciences was too clear to be resisted. He entered the service of the Museum of Natural History in Paris in 1868 as "aide-naturaliste," and eight years later he became a professor in that institution. On the death of Prof. A. Milne-Edwards in 1900, Perrier was appointed director of the museum, a position which he held until January of last year, when he retired with the title of honorary director. He died in his official residence at the museum on July 31 last.

Prof. Perrier's published writings cover a wide range of subjects. His own researches—morphological, taxonomic,. and faunistic—deal mainly with various groups of invertebrates, and are recorded in a long series of memoirs, many of which are of fundamental importance. His monograph on the structure of earthworms (1874) is frequently quoted by Darwin, who refers to it as "M. Perrier's admirable memoir." His researches on echinoderms are well known, and we need do no more than mention his memoirs on the collections of the *Travailleur* and *Talisman*, the *Blake*, and other expeditions, and his detailed study of the structure and development of Antedon. He was also the author of a considerable number of volumes of more general scope, one of the best known being "La Philosophie zoologique avant Darwin" (1884), in which he emphasised the important part taken by French thinkers in the development of biological theory. "Les Explorations sous-marines" (1886) was based largely on the results of the *Travailleur* and *Talisman* expeditions in the Atlantic, in which he had taken part. "La Tachygénèse, ou accélération embryologique" (in collaboration with Prof. Ch. Gravier, 1902), is an interesting and suggestive attempt at a synthesis of the facts of embryology. In his monumental "Traité de Zoologie," of which six fascicles have appeared since 1892 (a final part was in manuscript at the time of his death), he attempted a task which is now, perhaps, beyond the powers of any single man. His last published work, "La Terre avant l'Histoire" (1920), a general review of the origin and evolution of the living world, is distinguished no less by the author's encyclopædic knowledge than by the lucidity and charm of his style.

A list of Prof. Perrier's academic and other honours would be a lengthy one. He was elected a member of the Académie des Sciences in 1892; he was also a member of the Académie de Médecine, and of many foreign academies and learned societies, including the Linnean and Zoological Societies of London. The distinction of his literary style gained for him the coveted honour of admission to the "Société des Gens de Lettres," of which he was one of the few scientific members. He was one of the founders of the International Congress of Zoology, and succeeded Prof. A. Milne-Edwards as chairman of the permanent committee.

Of Prof. Perrier's personal qualities, a distin-

guished colleague and former pupil of his, to whom we are indebted for some of the facts recorded above, writes: "Je suis navré de la mort de mon vénéré Maître. . . . Il avait conquis les sympathies de tous par son caractère enjoué et si aimable, par son accueil charmant pour tous, les grands comme les petits, les puissants comme les faibles, par son exquise bienveillance. . . . Il restera de lui le souvenir d'un savant érudit d'une haute courtoisie."

A. T. SIMMONS.

MANY science teachers and students will learn with much regret that Mr. A. T. Simmons, inspector of secondary schools for the University of London, and author of a number of widely used text-books of science, died from pneumonia on August 19, at fifty-six years of age. Mr. Simmons received his chief scientific training at the Royal College of Science, London, in 1882–87, and during these years he and his fellow-student, Mr. H. G. Wells, were almost inseparable. After becoming an associate (physics) of the college, he was for three years lecturer in physics, chemistry, and other science subjects at the Southport Science and Art Institute, and while occupying this post he proceeded to work for the B.Sc. degree of the University of London, graduating with first-class honours in physical geography and geology in 1890. During the years 1891–97 he was science and second master at Tettenhall College, near Wolverhampton, where numerous students learned to esteem his high character and teaching aptitude. He came to London in order to undertake general editorial and advisory work for Messrs. Macmillan and Co., Ltd., in connection with school manuals on scientific subjects, and was a part-time member of the staff until his death. In association with Sir Richard Gregory, he founded in 1899 the *School World*, published by Messrs. Macmillan, and continued as joint-editor when that magazine was incorporated with the *Journal of Education* in 1918.

By his many years of devoted service on these periodicals, the sympathetic and helpful spirit in which he carried out his duties as inspector of science work in schools, and the assistance he afforded to many authors of text-books, Mr. Simmons won the highest regard from a large circle of the educational world. His influence upon the teaching of scientific subjects was strong and far-reaching, and his death will be mourned not only by his personal friends, but also by numerous teachers and students familiar with his books both at home and overseas. His personality and his works will long be cherished in most affectionate memory.

NEWS has reached us that one of the best Russian zoologists, PROF. N. A. CHOLODKOVSKY, academician and professor emeritus in the Academy of Medicine and at the Institute of Forestry, died last April in Petrograd at sixty-one years of age. Prof. Cholodkovsky was the author of numerous works on entomology and helminthology. One of his best works is a "Monograph on Chermes Injurious to Coniferous Trees," 1906. His excellent text-books on zoology are adopted in most Russian universities. To the general public Prof. Cholodkovsky was also known as a poet of high merit. To his pen belong the best translations into Russian of Shakespeare, Byron, Goethe, and others. For his masterly translation of Goethe's "Faust," with commentaries and a new criticism, he was awarded the Grand Premium in Literature by the Russian Imperial Academy of Sciences.

THE death is announced, in *Science* of August 12, of CHARLES BARNEY CORY, curator of zoology in the Field Museum of Natural History, which occurred on July 29, at the age of sixty-four years. Mr. Cory was one of the founders and a past president of the American Ornithologists' Union and a member of many learned societies, and was widely known for his ornithological writings.

Notes.

THE announcement appears in *Science* of August 12 that Prof. R. A. Millikan, of the University of Chicago, has been appointed director of the new Norman Bridge Laboratory of Physics at the California Institute of Technology, and chairman of the executive council of the institute. An income of 95,000 dollars for the new laboratory alone has been promised by the institute, and additional funds available comprise sums of 200,000 dollars and 50,000 dollars, which have been promised by Dr. Norman Bridge for the extension of the laboratory and its library respectively. With this generous provision it is hoped to create a large and effective laboratory for research in physics. In conjunction with the laboratory, the Southern California Edison Company is to erect an experimental station in the grounds of the institute for the investigation of the transmission of electric power at high potentials; Prof. Millikan will be partially responsible for the direction of this station. The main problem, however, which Prof. Millikan proposes to attack is the constitution of matter and its relation to the phenomena of radiation, a task for which the new laboratory will provide exceptional opportunities. It is also announced that Prof. H. A. Lorentz, of the University of Leyden, will be in residence at the institute during the winter term as lecturer and research associate in order to supplement the work of the mathematical physics department, and that Dr. C. G. Darwin, of Cambridge, has been appointed professor of this department for the academic year 1922–23.

THE council of the British Association for the Advancement of Radiology and Physiotherapy has recently issued a statement warning the public against

undue optimism about the use of radiotherapy in the treatment of cancer. The new technique, which has been developed at Erlangen, Bavaria, has not yet been thoroughly tested, and, in any case, evidence of success cannot be assumed until after the lapse of some years. The council is of the opinion that of any single method surgery still offers the best prospects of cure in most cases of cancer. Combined treatment by operation and radiation therapy has been employed with good results, and so far the co-operation of the radiologist with the surgeon affords the greatest hope of success. The association has organised a scheme for the investigation of the claims made for the new intensive X-ray treatment, for which purpose a sum of 4000*l.* has been allocated by an anonymous donor (*Arch. Radiology and Electrotherapy*, No. 252, July, 1921, p. 38). It is suggested that a research scholar be appointed for two years at a salary of 350*l.*, with travelling allowance, and that he proceed to Erlangen, where the treatment has been in progress for several years. If it is found that the results obtained there approach the claims made, a complete outfit of apparatus such as that used at Erlangen would be ordered and installed at the Manchester Royal Infirmary and the work continued there.

THE President of the French Republic has conferred the Cross of Chevalier of the Legion of Honour on Col. Sir Arthur Mayo-Robson for services rendered by him to the French Red Cross during the war.

IT is announced that the Advisory Committee provided for by the Importation of Plumage (Prohibition) Act will be constituted as follows:—Lord Crewe (chairman), Mr. E. C. Stuart Baker and Dr. W. Eagle Clarke (representing ornithology), Mr. C. F. Downham, Mr. W. G. Dunstall, and Mr. L. Joseph (representing the feather trade), Lord Buxton, Capt. E. G. Fairholme, Mrs. Reginald McKenna, and Mr. H. J. Massingham.

AT a meeting of the Privy Council, held at Buckingham Palace on August 10, the petition of the Institution of Electrical Engineers for a Royal Charter of Incorporation was approved, and a Royal Charter has now been granted. His Majesty the King has also been graciously pleased to intimate his willingness to become patron of the institution.

IT is announced in *Science* of August 5 that the Municipal Observatory at Des Moines, Iowa, said to be the only municipal observatory in the world, was opened on August 1. The observatory building is to be equipped by Drake University with an 8-in. equatorial telescope. It is to be under the control of the university, and open to the public at least three times a week, and at any other time when occasion may warrant.

CAPT. ROALD AMUNDSEN has arrived at Vancouver from Nome, Alaska. The *Times* announces that he intends to sail for the Arctic next spring to resume his attempt to drift across the Arctic Ocean. Two aeroplanes furnished with sleds will be carried by the expedition. Meanwhile the *Maud* is on her way to Seattle for repairs and the installation of more powerful wireless equipment. It will be recalled that the *Maud's* first attempt to drift with the pack was unsuccessful, and that she was forced to winter in the ice off the coast of north-eastern Siberia, where she lost a propeller.

ANNOUNCEMENT was made of the coming Paris meeting of the Iron and Steel Institute, under the presidency of Dr. J. E. Stead, in NATURE of June 2, p. 434. A programme of the meeting, which will be held at the headquarters of the Comité des Forges de France on September 5 and 6, has now been issued. It is expected that ten papers will be submitted, most of them dealing with the constitution and properties of various types of steel, though two will be of economic interest. Advance copies of the papers can be obtained by members of the institute from the Secretary, 28 Victoria Street, S.W.1. At the conclusion of the meeting, alternative visits have been arranged to works in Lorraine, Burgundy, and Normandy.

IT is reported in the *Pioneer Mail* of July 15 that the Bose Research Institute, established some four years ago at Darjeeling, is actively at work and engaged in investigations of wide interest. The Government of India has obtained the consent of the Secretary of State for a permanent Imperial grant which will be double the income derived from public donations, of which Sir J. C. Bose's contributions alone will amount to 10 lakhs of rupees (66,666*l.*). Problems dealing with agriculture will be investigated on an experimental station at Sijberia, while at Darjeeling an attempt is to be made to conserve an entire hill-side with the view of investigating the flora of the district and of preserving wild plants from Sikkim and Tibet which are in danger of extermination.

AT a small business meeting held on August 16 at the Hotel Cecil, the Society for Constructive Birth Control and Racial Progress was formally constituted, with Dr. Marie Stopes as president. The objects of the society are: (*a*) To bring home to all the fundamental nature of the reforms involved in conscious and constructive control of conception, and the illumination of sex life as a basis of racial progress; (*b*) to consider the individual, national, international, racial, political, economic, scientific, spiritual, and other aspects of the theme, for which purpose meetings will be held, publications issued, and research committees, commissions of inquiry, and other activities organised from time to time as circumstances require and facilities offer; (*c*) to offer to all who still need it the full knowledge of the methods of control.

A CONGRESS of Applied Chemistry, to be held in Paris on October 9–12, is being organised by La Société de Chimie Industrielle de France. The congress, which will also be the first annual meeting of the society, will be split up into thirty-four sections, corresponding to various branches of industrial chemistry. All meetings will be held in the Con-

servatoire des Arts et Métiers, and the inaugural ceremony, which will take place on October 10, will be presided over by M. Dior, the French Minister of Commerce. The society is also organising, at the Conservatoire, a Chemical Exhibition, which will be open on October 9–16. Two sections only will be represented, those dealing with laboratory equipment and colouring matters, but it is hoped that the exhibition, at which most French manufacturers will be represented, will be the germ of a future chemical exhibition embracing all branches of industrial chemistry.

THE latest news from the Mount Everest expedition is contained in Col. Howard Bury's dispatch to the *Times* published on August 17. Leaving their base camp at Tingri, the expedition explored the approach to Mount Everest on the north-west. The chief obstacles were great glacier streams which proved quite unfordable in July, and could be crossed only where frail native bridges existed. The expedition crossed the Kyetrak glacier valley on such a bridge, and marching by Zambu reached the Rongbuk glacier, in the valley of which it camped at a height of 18,000 ft., some miles from the great Rongbuk Monastery, which stands at 16,500 ft. Progress in this direction did not look promising owing to the sheer precipices of 10,000 ft. which descend to the Rongbuk glacier, and even supposing the ridge summits at 26,000 ft. were gained, there still remains difficult rock climbing at greater heights. In the course of their reconnaissance Mr. Mallory and Mr. Bullock climbed a peak of more than 23,000 ft., but their coolies were unable to reach the summit. August was to be devoted to the eastern and north-eastern faces of Mount Everest, which have more snow and ice on them than the north-western side, and the base camp for this purpose was to be moved in the vicinity of Kharta, in the Arun Valley. Col. Howard Bury hopes to find a high pass leading from the Rongbuk glacier into the valley of the Kharta Tsangpo, but finds it impossible to get any accurate information from the Tibetans. The weather broke early in July, and poor visibility now hampers the work.

THE widespread faith in Australia in water-divining has led Dr. Griffith Taylor to examine its working in the Federal Capital Territory, and he has communicated his conclusions and some quotations from the literature of the subject to the Proceedings of the Royal Society of Victoria (vol. xxxiii., N.S., 1921, pp. 79–86). He dismisses water-divining as of no practical value and as of interest to the psychologist rather than to the geologist or farmer. His own evidence, however, like some other scientific tests of the question, is inconclusive. He reports two cases. A well was sunk at Ainslie at a point selected by a diviner, who "estimated that water would occur at about 56 ft." Dr. Taylor reports that "at 56 ft. some water came in; at 64 ft. water was 'bubbling in.'" In this case the well was sunk in an area where drifts lay on a slope of impermeable beds, and water could have been obtained at any site. This success was probably mere coincidence, but the prediction was justified by the result. In the second case another diviner recommended a site on a ridge of shale; naturally, the well was a complete failure. Dr. Taylor quotes records of more extensive inquiries, including the Guildford case of 1913, an early investigation by the Government of South Australia, and one in 1920 by the New South Wales Water Conservation Commission. This Commission's inquiry covered fifty-six bores selected by diviners, and of these 70 per cent. were successful; of ninety-six bores selected without the diviners' aid 87 per cent. were successful. The accumulation of evidence against the divining-rod is useful, and though it may show that the method is of no practical value, many of the tests are not conclusive against those who consider that certain individuals in suitable circumstances are influenced sub-consciously by underground water.

SIR FREDERIC KENYON'S presidential address to the Museums Association, in which he set forth his views as to the future development and arrangement of the British Museum (*see* NATURE, July 28, p. 689), is now published in the August issue of the *Museums Journal* (Dulau and Co.).

REFERRING to recent correspondence in NATURE, Mr. A. S. E. Ackermann writes to say that in August of last year at Ypres he saw bumble-bees abstracting nectar from the flowers of white-runner beans through a hole in the side of the corolla instead of in the normal manner.

THE camera is being used increasingly to elucidate the habits of birds, and striking success has been achieved by Dr. Overton in his observations on the great horned owl, described in *Natural History* (vol. xxi., No. 2). It has hitherto been supposed that the bird attacks its enemies and prey by means of its wings or bill. The remarkable series of photographs which are used to illustrate Dr. Overton's article clearly demonstrates, however, that the bird attacks solely with its feet. We have seldom seen so conclusive a collection of photographs of birds.

IN the June issue of the *Lancashire and Cheshire Naturalist* Mr. R. Standen records some interesting observations of his own and other naturalists on the feeding habits of squirrels, with particular reference to fungi. He has watched squirrels feeding on that most poisonous of fungi (to man), the Fly Agaric (*Amanita muscaria*). They were observed to knock off the cap and to eat only the stalk, but so far as is known they were none the worse, and appear to be immune to this particular form of poison. The late Rev. O. Pickard-Cambridge has recorded squirrels as eating *Boletus edulis*, and Mr. Britten has watched them feeding on the Blusher (*Amanita rubescens*), but both these species are non-poisonous. In America squirrels are known to store fungi with their other food, but British squirrels have not as yet been observed to follow this habit. Mr. Standen's notes raise many interesting points, such as the distribution of the poisonous substance in the tissues of the fungus, and the degree of immunity enjoyed by the squirrels. It is clear that there is much to be learnt about the natural history of our British mammals.

THE diminutive shrunken heads made by the Jivaro Indians have long been familiar objects in our museums. In *Natural History* (vol. xxi., No. 2) Mr. C. W. Mead gives an account of how and why they were made. The head, with a small part of the neck, is severed from the body. A cut is made from the base of the skull down through the neck, and through the opening thus made the bones of the skull are carefully removed. The skin and the remaining soft parts are next dipped in the juice of the *huito* fruit, which stains them black. The skin is then ready for the shrinking process. This is done by putting a number of hot stones into the cavity and constantly turning the head in order to bring all parts in contact with the stones. This process is repeated until the head is reduced to the required size. Among some of the tribes a single hot stone nearly as big as the head is used, and replaced by smaller ones until the work is completed. Hot sand is also used in some localities. The lips are then fastened by long pendent cords, and one is run through the top of the head to suspend it. Finally, the cut in the back of the neck is sewn up, and the trophy is completed. Originally a tribal custom of celebrating a victory over an enemy, the Jivaro Indian was not slow to turn it to commercial use when he found that the heads were in great demand among white men. We are told that advance orders were booked and in due course filled.

DR. MARIANNE PLEHN directs attention in an article in the *Allgemeine Fischerei-Zeitung* for August, a translation of which has been sent to us by the Editor of the *Fishing Gazette*, to what she regards as a hitherto unrecognised cause of disease in fish kept in tanks and ponds: this is an excessive quantity of oxygen in solution in the water. It is well known that an abundant growth of algæ in fish cultural ponds may be very injurious. So much oxygen is given off by the plants that the water may effervesce when it is stirred violently. In such circumstances more of the gas is taken up by the blood of fishes than can be used in the ordinary way by the tissues, and then a further rise in the water temperature may cause the liberation of gaseous oxygen in the blood. Vesicles, visible to the naked eye, are said to form in the skin, particularly on the fins. Similar gas vesicles may form in the orbits, giving rise to "exophthalmos." Gas embolisms may even form in the heart and vessels of the gills, causing immediate death. Not only oxygen, but also nitrogen, may, at times, be contained in solution in freshwaters to such an extent as to be the occasion of this "Gaskrankheit," and the author also suggests that gas-forming bacteria in the blood of fishes may be the cause of similar effects. The matter is one of much importance in salmon and trout hatcheries, and, quite evidently, it should be the subject of very careful investigation.

A TELEGRAM from Asmara (Eritrea) reports a rather severe earthquake in that region on or shortly before August 15. The shock was especially strong at Massowah and in the surrounding country, at least four people being killed and about twenty injured, while several houses collapsed. As a rule the earthquakes of Eritrea are infrequent and of slight intensity. Prof. Palazzo, in his catalogue of Ethiopian earthquakes from 1400 to 1912 (Boll. Soc. Sism. Ital., vol. xix., 1915, pp. 293–350), records 142 shocks, the strongest of which occurred in 1400, 1884, and 1901. Asmara itself seems to be one of the least stable regions. Early in 1913 (from January 24 to April 8), 208 disturbances were registered at the seismological station in that place, the strongest of which was of about the same intensity as the recent earthquake.

IT is satisfactory to learn that the valuable work of the Kilauea Volcano Observatory is to be maintained, if not extended. Under the supervision of Dr. T. A. Jagger, jun., and supported by the Hawaian Volcano Research Association, all changes in the activity of the volcano have been chronicled for some years, and the earthquakes, local and otherwise, have been registered. In 1918 a grant of ten thousand dollars was made by Congress, and at the same time the question of placing the observatory under Government direction was considered by a committee of the National Academy of Sciences. On its advice the control of the Kilauea Observatory has been transferred to the Weather Bureau. The full report of the committee has now been published (Proc. Nat. Acad. of Sciences, vol. vi., 1920, pp. 706–16). A general scheme of investigation in either seismology or volcanology is, it considers, beyond the proper scope of the Weather Bureau. For the present, the committee suggests that seismographs might be added at certain selected meteorological stations, and that such work should, if possible, be placed under the direction of a trained seismologist belonging to the Bureau. While the maintenance of the Kilauea Observatory is regarded as of the first importance, the committee recommends that observations should be made on all the active phases of Hawaian volcanism, and that, especially, the gigantic volcano of Mauna Loa, which represents a different stage in the development of a basaltic volcano, should be subjected to an investigation as systematic as may be possible, taking into account its much greater size and the difficulty of access.

THE hydrous calcium borate inyoite, described by W. T. Schaller from California in 1916, has now been found at a second locality, the Whitehead gypsum quarry, Hillsborough, Albert County, New Brunswick. E. Poitevin and H. U. Ellsworth describe a number of crystals, confirming the monoclinic character of the mineral (Canada Depart. of Mines, Geol. Surv., Bull. 32, 1921). It is "fairly soluble" in water, and separated out somewhat later than the massive gypsum, in the cracks of which it lies.

THE Geological Survey of Ireland has issued through the Ordnance Survey two new sheets of the geological map of the country on the scale of a quarter of an inch to a mile (1 : 253,440). Sheet 5 covers a region of unusual interest, and should be specially useful to dwellers in Belfast. Educationally, it serves as an epitome of the geology of Ireland. It includes the

gneissic axis of Tyrone, the Caledonian area of Armagh and Down, with the Newry granite in its strike, the down-faulted Carboniferous series of Coal Island, and the Cainozoic granite of the Mournes. The Mesozoic beds, protected by the great plateaus of basaltic lavas, are well seen encircling Lough Neagh. Sheet 16 offers less variety, and shows the rapid succession of Armorican anticlines and synclines in the Devonian and Carboniferous systems round Cork city.

IN a short paper to the International Congress of Mathematicians, Strasburg, 1920, entitled "Une application des polynômes d'Hermite à un problème de statistique," Prof. Alfred Guldberg, of Christiania, reaches the series recommended for the representation of frequency curves and surfaces by Edgeworth in this country, and by Charlier, Thiele, Bruns, and others on the Continent. The large amount of mathematical work on such subjects that is being done in Scandinavia is noteworthy, but the application of the results of the mathematical work on a large scale to a great variety of statistics seems to be required if we are to estimate the usefulness of the work in practice.

THE report of the Royal Observatory, Hong-Kong, for the year 1920 by Mr. Claxton, the director, shows that the usual meteorological and magnetic results have been continued. Automatic records of the temperature of the air and evaporation were obtained with a Richard dry- and wet-bulb thermograph, and the direction and velocity of the wind with a Beckley and a Dines-Baxendell anemograph. The amount of rain is recorded automatically by a pluviograph, and the amount of sunshine is registered by a Campbell-Stokes recorder. Other observations are recorded by eye. The mean barometric pressure and mean temperature for the year were in fair agreement with the normals. The total rainfall for the year was 107·88 in., which is about 24 in. above the normal. The fall in an hour measured 1·44 in. on September 12, and 12·70 in. fell in forty-nine hours on July 18–21. Tracks of sixteen typhoons and four of the principal depressions which occurred in the Far East in 1920 are given in the Monthly Meteorological Bulletin for December. Observations from the Philippines are now received in time for insertion in the daily weather map. Wireless weather telegrams were received from 140 ships in the course of the year, and meteorological registers from 170 ships operating in the Far East. Upper-air research is being considered, as is also the installation of a seismograph.

THE *Meteorological Magazine* for July has an article on the design of rain-gauges, which affects largely the accuracy of rainfall measurements, now being considered with greater assiduity than in the past. The 5000 observers for "British Rainfall" show the necessity for uniformity and precision in the style of gauge. Universal adoption of the now recognised standard patterns of rain-gauge is advocated, and the rejection of certain obsolete patterns. The forms approved are the Snowdon gauge and patterns based on it, such as the Bradford gauge, the Meteorological Office pattern gauge, and the Seathwaite gauge. Some of the essential features given of an approved gauge are: The stout brass turned ring terminating upwards in a knife-edge, exactly 5 or 8 in. in diameter, which forms the rim of the gauge; the vertical cylinder, 4 to 6 in. deep, extending from the rim to the upper edge of the funnel, which is intended to retain snow and hail, to prevent the outsplashing of rain which has fallen upon the funnel, and to reduce to a minimum the risk of loss due to wind eddies; an inner collecting vessel, which can be removed for measuring the fall without disturbing the body of the gauge, the latter being slightly sunk in the ground; and a capacity of not less than 10 in. of rain for a daily gauge. Hints relative to self-recording gauges are also given. Makers of rain-gauges are asked to assist in the elimination of undesirable types of rain-gauge.

SINCE its introduction in 1829 the Trevelyan rocker has formed the subject of many scientific papers, but they have all led to the conclusion that Faraday's explanation of the motion of the rocker was substantially correct. According to Faraday the motion is due to the expansion of the material of the support under one of the two ridges on the under-surface of the rocker by heat communicated to the material from the rocker. This expansion throws the rocker on to its other ridge, allowing the first portion of heated material to cool until it is again the support for the rocker. This theory was put into dynamical form by Davis in 1873, and has been accepted as satisfactory. A recent study of the actual motions of a rocker carried out by Prof. Chuckerbutti, of Calcutta University, and given in vol. vi. of the Proceedings of the Indian Association for the Cultivation of Science, shows, however, that the theory is quite unsatisfactory. The tones produced are those of the elastic vibrations of the system composed of the rocker and its handle, and the pitch of each is determined by these vibrations under the constraints imposed on the rocker by the method of support.

THE third paper on the physical properties of clay, read by Mr. A. S. E. Ackermann before the Society of Engineers, contains a record of forty-nine more experiments, which carry our knowledge of this subject considerably further. By boiling the clay and allowing it to settle, some of the colloidal matter was got rid of, and as a result the pressure of fluidity was decreased by about 25 per cent. When a disc is pressed into a mass of clay, the mean radial speed of flow of the clay underneath the disc is about one-eighth the speed of penetration of the disc, and the mean speed of penetration of the disc when the load on it is just sufficient to produce the pressure of fluidity is about 1 cm. per minute. Some interesting experiments were made with the view of ascertaining the behaviour of the clay immediately below the disc; there appears to be a stagnant cap of clay which remains in contact with the lower side of the disc and travels with it. Even under considerable tangential stress there is no progressive strain in clay containing 25 per cent. of water, which

thus behaves as a solid. The addition of an artificial head to the top surface of the same clay increases the pressure of fluidity by about 7 per cent. when the addition is 200 per cent. of the actual head. The experiments on discharging clay under pressure through sharp-edged circular orifices are also of interest. The rate of discharge increases more rapidly than the rate of increase of pressure, and ultimately there is a phenomenon analogous to the pressure of fluidity. Reducing the size of the orifice, keeping the pressure constant, reduces the discharge per unit area of orifice. The initial pressure necessary to cause the discharge to begin increases considerably as the diameter of the orifice is decreased. Practically the same result is obtained whether a disc or a sphere is used in determining the pressure of fluidity, and the result is independent of the diameter of the disc or sphere within a considerable range. Mr. Ackermann's work on this subject shows promise of great value to engineers in dealing with foundations and retaining walls, and we trust that his experimental work will be continued.

Our Astronomical Column.

The Recent Meteoric Display.—Mr. W. F. Denning writes that further proof of the unusually abundant display of August meteors is provided by Mr. S. B. Mattey, observing at St. Helier, Jersey, on August 11 during the quarter of an hour between 14h. and 14h. 15m. G.M.T., who saw sixty-two meteors. This indicates a rate of about 250 per hour, and proves that the shower was witnessed in extraordinary activity. About 25 per cent. of the meteors seen by Mr. Mattey were bright ones, exceeding stars of the first magnitude. Their light was frequently strong enough to illumine buildings near his place of observation; in fact, he describes the effect as being somewhat similar to that occasioned by so-called sheet lightning.

Detection of Encke's Comet.—A letter from Mr. J. F. Skjellerup, dated Capetown, July 29, announces that he and Mr. W. Reid detected Encke's comet on July 27 at 5h. 15m. G.M.T., when it preceded 19 Sextantis by 31 seconds, and was 2′ to the south of it, which makes its apparent position R.A. 10h. 8m. 11s., N. decl. 4° 58′. The estimates of its magnitude by the two observers were 9·5 and brighter than 8·0.

The following elements were predicted by Mr. Matkiewitch:—

$$\begin{aligned} T &= 1921 \text{ July } 13{\cdot}28 \text{ G.M.T.} \\ \omega &= 184^\circ\ 43{\cdot}5' \\ \Omega &= 334^\circ\ 35{\cdot}5' \\ i &= 12^\circ\ 31{\cdot}1' \\ \log a &= 0{\cdot}34598 \\ e &= 0{\cdot}84671 \\ \log q &= 9{\cdot}53149 \end{aligned}$$

The above observation would indicate a value of T some 0·2 day earlier than the prediction.

The comet will be 1921 *d*.

The letter states that Pons-Winnecke's comet was observed at midnight on July 27, in R.A. 1h. 24m., S. decl. 38°, magnitude about 8·5.

Study of the Moon's Surface.—Mr. Walter Goodacre has just brought out the eighth report of the Lunar Section of the British Astronomical Association. He dwells on the immense value in selenography of the splendid photographs taken by Mr. F. G. Pease with the 100-in. Mount Wilson reflector. He states that they show more detail than a 6-in. visual telescope would do, even with the best seeing. The report contains several charts showing on a larger scale much of the detail that has been detected on the photographs. One is of the "Straight Wall near Thebit," showing that it is really by no means straight. Enlargements of the craters Ptolemaus, Clavius, Copernicus, Arzachel, Gassendi, etc., show much new detail, mostly of the nature of tiny craters or narrow clefts. Mr. Goodacre considers that the new evidence is unfavourable to the theory of meteoric formation of the lunar features. Various fine details are noted, in particular an apparent landslip on the wall of Birt A.

Mr. J. W. Durrad contributes a fine drawing of Gassendi, showing numerous clefts on the floor, some of which are new.

The Distances of the Globular Clusters.—The Bulletin of the National Research Council, Washington, D.C., for May last contains an interesting discussion between Dr. Harlow Shapley and Prof. H. D. Curtis on this subject. Taking the Hercules cluster as an example, they contend respectively for 36,000 and 3600 light-years as its distance. The strongest argument for the former distance is the presence of B stars in the cluster and the demonstration that the average absolute magnitude of such stars is zero or brighter, judging from the stars in proximity to the sun. Prof. Curtis prefers to work from the average absolute magnitude of all stars within measurable distance, but Dr. Shapley replies that the average is itself a function of distance, since the stars that are really very faint are altogether lost to view at moderate distances.

Another point discussed is the correlation between period and absolute magnitude in the Cepheid variables. Prof. Curtis gives a diagram showing that the case for this correlation becomes much less convincing than Dr. Shapley had supposed, when the number of galactic Cepheids employed is increased. Dr. Shapley replies that he used the Cepheid method solely as corroborative of several others, and that the strongest argument for the correlation is in reality deduced from the fact that the methods all fall into line so well.

The discussion also involves the status of the spiral nebulæ. Dr. Shapley's estimate of the size of our Galaxy is so great that if the spirals were similar objects they would be so remote that we could not expect to see novæ in them. From the fact that several novæ have been detected he concludes that they are not stellar, but actually formed of diffused matter. Prof. Curtis's smaller galactic diameter permits the view that the spirals are external galaxies. He estimates the distance of the Andromeda nebula (supposed to be the nearest spiral) as 500,000 light-years, and invokes the presence of a zone of occulting matter near the galactic plane to explain the observed distribution of the spirals.

The discussion is highly instructive, and the method of putting the two views of such difficult questions side by side is most helpful as a check on over-hasty deductions and a test of the weaker links in a chain of evidence.

New Facts of Colour Vision.

By DR. F. W. EDRIDGE-GREEN.

THE White Equation.—The fact that when two or three simple spectral colours are combined a white is produced which matches that from which the spectrum has been formed is the basis of many theories of colour vision. It is therefore of fundamental importance to any theory of colour vision.

In a recent paper (Proceedings of the Royal Society, B, vol. xcii., 1921, p. 232) it was pointed out that when an exact match of a red of λ 6670–6770 Å., a green of λ 5144–5156 Å., and a violet of λ 4250–4267 Å. with white was made, after fatigue with red light in the region of λ 670μμ, there was no longer a match between the simple and mixed whites, the mixed white appearing bright green, and in order that a match could be made the green had to be reduced to about one-half of the amount required by an unfatigued eye. It is obvious, therefore, that the underlying physiological processes are not the same with the mixed and simple whites. It should be noted, however, that no change in the equation is seen when the eye is fatigued with red light in the region of λ 780μμ.

Another fact of colour fatigue bears on this point; red of λ 670μμ can be matched with red of the end of the spectrum by varying the intensity, and so it has been stated that red λ 670μμ, as well as the terminal red, affects only the hypothetical red sensation. If, however, the eye be fatigued with red of the region of λ 760μμ, and red of the region λ 670μμ be afterwards viewed, this appears yellow, or even greenish-yellow, which could not be the case if the red sensation only had been affected.

The Change of Hue produced by the Addition of White Light to Spectral Colours.—White light is a purely relative term. The white light of the sun is not the same as that from an artificial source; the term is therefore employed as meaning the combined light of the source which is used. In making the experiments described, the light was that of a 1000-candle-power tantalum arc, which, compared with sunlight, is yellow. The apparatus used in these experiments was that described in the Proceedings of the Royal Society, B, vol. xcii., 1921, p. 232.

Various spectral colours were isolated on a screen coated with magnesium oxide, and definite proportions of white light taken from the source added. The scale of white light is arbitrary, the maximum amount of light it is possible to add being 100 divisions. A comparison white light taken from the source was used. Each colour became less saturated on adding white light. Red first became orange, then yellow. Orange became yellower. λ 585μμ, pure yellow, did not change in hue. Orange-yellow and yellow-green became yellow. Green became yellow-green. Blue, λ 480μμ, became white, the comparison white appearing yellow. The violet end of the spectrum from λ 480μμ, making a blue on the screen, changed to violet on adding 33 divisions of white light; light purple, on adding 100 divisions. Wave-length 585μμ, the point where the addition of white light produces no change of hue, is also the centre point of pure yellow and the apex of the luminosity curve.

The result of these experiments shows that the component part of white light which has the greatest luminosity effect is the hue to which all colours tend on the addition of white light.

The Anomalous White Equation without Colour-blindness.—Just as a man may make an anomalous Rayleigh equation without any evidence of colour-blindness (Proceedings of the Royal Society, B, vol. lxxxvi., 1913, p. 164), so may a man make an anomalous white equation without being colour-blind. As an example of this, a man was examined who presented no sign of colour weakness. He passed my card test, lantern test, and spectrometer with the ease and accuracy of an absolutely normal-sighted person. His luminosity curve was taken by the flicker method and corresponded with the normal. The wave-length of the apex of the luminosity curve was at 585μμ, which is the normal point. When, however, his white equation was taken, he put only eight scale-divisions of green instead of thirteen and a half or fourteen, which is normal, and the mixed light appeared red to the normal-sighted. An important fact was noted, namely, that after fatigue with red in the region of λ 670μμ the equation changed to him in the same way as the normal-sighted, and he required only four scale-divisions of green instead of eight. It is quite obvious that this was not a case of partial red-blindness.

The White Equation and Colour-blindness.—The colour-blind have been classified by some as red- or green-blind, in accordance with their white equations, those who put too much red in the equation being classed as red-blind and those who put too much green in the equation being classed as green-blind. There are, however, many who, whilst agreeing with the normal equation, are quite satisfied when a considerable additional amount of green or red is added to the equation. This explains why in certain cases some have been described as red-blind by one observer and green-blind by another.

A remarkable fact which does not seem to have been previously observed is that many colour-blind persons who strongly object to the normal match, but are satisfied with an anomalous equation, will completely agree with the normal equation when the comparison white light is increased in intensity so that it is much too bright to a normal-sighted person. This clearly shows that the normal mixed white produces the same effect so far as colour is concerned, but has a more powerful effect as to luminosity. This is in complete accordance with other observations, and is found in those cases in which there is abrupt and slight shortening of the red end of the spectrum. If there be shortening of the red end of the spectrum which does not affect λ 670μμ, and λ 670μμ has its normal light value, the mixed light will be more luminous than the simple white in the exact proportion of the shortening. This portion of red light not producing any effect has to be subtracted from the white light.

These facts are quite inconsistent with a hypothetical red sensation which is affected by light of all wave-lengths. Another illustration may make this point clear. A man with shortening of the red end of the spectrum and normal colour discrimination will put together as exactly alike a pink and a blue or violet much darker. If, however, the pink and blue be viewed by a normal-sighted person through a blue-green glass which cuts off the red end of the spectrum, both will appear identical in hue and colour. This proves conclusively that the defect is not due to a diminution of a hypothetical red sensation, because all the rays coming through the blue-green glass are supposed to affect the red sensation, and yet we have been able to correct the erroneous match by the subtraction of red light. On the other hand, there are colour-blind persons who, whilst dis-

agreeing with the normal white equation, agree with it when the comparison white is diminished in intensity.

The facts in this article, whilst in complete accord with those previously given ("The Physiology of Vision," G. Bell and Sons, 1920), are inconsistent with any theory of three fundamental sensations of which the other colour sensations are compounded.

Defects of light perception are quite distinct from defective colour discrimination. All degrees of colour discrimination may be classified as dichromic, trichromic, tetrachromic, pentachromic, hexachromic, and heptachromic. This classification is fact—and not theory. For instance, the dichromic have two colour sensations, red and violet, with a neutral division in the spectrum. There are innumerable varieties of dichromic vision, as there may be shortening of either end of the spectrum or defects in the luminosity curve. When the luminosity curve is the same as the normal there is no evidence to show that the perception of white is not the same as the normal.

I must express my indebtedness to Capt. Fulton and Mr. Isaacs, of the Board of Trade, for their help in making these observations.

Regional Geology.

Our knowledge of the geology of England is enriched by Dr. J. E. Marr's conception (*The Naturalist*, February, 1921) of Yorkshire as an earth-block surrounded by down-folded strata, but with its own Carboniferous series little disturbed, owing to the rigidity of a pre-Cambrian mass beneath. The block, which became tilted somewhat to the east, has had an important effect on the drainage, and even on the progress of ice-sheets, in northern England.

A useful summary and map of the geology of Jersey, by G. H. Plymen, appear in the Proceedings of the Geologists' Association, vol. xxxii., p. 151 (1921), a journal that has maintained its characteristic features despite the difficult conditions following on the war. The Geological Survey should find a ready sale, even at the price of 10*s.*, for its "Short Account of the Geology of the Isle of Wight," by H. J. Osborne White (1921), which contains a coloured geological map on the scale of one quarter of an inch to one mile. The second edition of the memoir that it succeeds is now exhausted, and we must look back on that handsome cloth-bound volume, issued at 8*s.* 6*d.*, with the customary regret. But Mr. White's treatise is not a mere abridgment of the older one, since he brings to the work his wide knowledge of the south-east of England, and of the literature of the intervening thirty years. He adds original drawings, showing the development of the surface and the relations of the rocks to well known scenic features, and geologists who are fortunate enough to possess the memoir by Reid and Strahan must now add its successor to their libraries before they start once more for the island. Here, again, the question is raised as to whether memoirs by public surveys should be supposed to cover their own "cost of production," or whether their dissemination should, as in Canada and the United States, be regarded as a part of public education.

Dr. Arthur Winkler, as Ordnance-officer of the 7th Gebirgsbrigadecommando, was stationed at Santa Lucia, near Tolmino, in 1916, and found time to extend F. Kossmat's researches on the central Isonzo valley. He remarks, in the true spirit of science, that the war had inflicted wounds on the mountain-sides, and that many new exposures required registration. His observations, continued in 1918, are now recorded in a paper in the *Jahrbuch der geologischen Staatsanstalt,* vol. lxx., pp. 11–124 (1920), illustrated by numerous sections showing the Alpine folding of the strata, from the Triassic limestones to flysch of Eocene age. Glacial beds, dumped down into the valley, play an important part in the dusty groove, and walls of pebbly calcicrete are undermined by the green swirls of the Isonzo. Above them tower the crags of contorted limestone, marked by brown scars where slabs of rock have fallen away. Dr. Winkler's work brings back happier memories than those recently associated with the Bainsizza Plateau and Caporetto.

The Geological Survey of India issues a handsomely illustrated memoir, by C. S. Middlemiss, on Idar State, which lies on the tropic in the north-east of the Bombay Presidency. Evidences of solar weathering are given in the fine views of granite surfaces. The main interest of the district lies in the junction of the Delhi quartzite with the underlying series of Aravalli schists and gneisses. Quartzite blocks again and again appear to be stoped off into the Aravalli rocks; but the latter cannot in all cases be regarded as igneous invaders. The author suggests that the igneous masses which penetrate the Aravalli series softened the metamorphosed sediments until they behaved as a semi-solid or plastic mass. The floor of Finland seems to offer much support to his conclusions.

Dr. W. F. Hume, untiring in his surveys of barren lands, has issued, with his colleagues, a preliminary report on Abu Durba (Western Sinai). This bulletin, dated 1921, is No. 1 of a series on petroleum research. The oil that is traceable at Abu Durba seems to have been absorbed from shales into the Nubian sandstone, and may originate (p. 11) in organic matter washed down with the shale-particles into the Cretaceous sea.

A. L. Du Toit (Union of S. Africa, Geol. Surv., Explanation of Cape Sheet 28, 1920) traces in Pondoland the great monoclinal flexure that, as Penck showed, is responsible for the edge of the plateau-lands of south-eastern Africa. The down-folding has determined the coast-line, and ceased about the close of Cretaceous times. The inland region, however, continued to rise, since Upper Cretaceous beds, near East London, occur 1100 ft. above the sea. The shelves over which the rivers reach the sea represent successive stages of the uplift. One is inclined to ask once more: When was the great peneplain of the plateau-surface formed? How has it escaped dissection inward from its Eocene edge? Has it been perpetuated by wind-action in a region where rains are only seasonal and droughts are more prevalent than rains?

The first pamphlet of the Geological Department of Uganda (Entebbe, 1920) is written by E. J. Wayland, and is intended to direct the attention of residents to the interest of geological features. The prevalence of laterite is discussed; but we should hesitate to say that the iron was "from the first" in the state of hydrous oxide. Glauconite, mentioned in connection with clays, is a silicate and not a phosphate. Are not the cubic pseudomorphs in the argillites (p. 11) more likely to have been originally pyrite than rock-salt? The author introduces (p. 36) a useful geographical term, *arena,* for undulating areas more or less completely surrounded by hill-ranges. These areas are shown to result from the denudation of domes of strata, and rivers run through the surrounding walls. The Woolhope inlier may thus be called an arena, and numerous examples occur in the

Old Red Sandstone and Silurian country of Southern Ireland.

From Australasia we receive comprehensive descriptions of the "Palæozoic Geology of Victoria," by E. O. Teale (Proc. Roy. Soc. Victoria, vol. xxxii., p. 67), with a map of the Mount Wellington area; also of the "Geology of Western Australia," by A. Gibb Maitland, extracted from the Mining Handbook published in 1919 by the Geological Survey. The latter memoir has excellent sketch-maps and illustrations throughout the text, and includes a large coloured geological map of the State, dated 1920, corresponding with that described in NATURE, vol. cv., p. 498. This summary should be serviceable in very many libraries in the homeland, and should be made available in all Australian schools.

In Bulletin 21, at the moderate price of 5*s.*, the New Zealand Geological Survey continues its illustrated descriptions of the Dominion. The Osborne and Whatatutu subdivisions, which are here dealt with by J. Henderson and M. Ongley, lie on the east side of North Island, and include peaks rising to 4000 ft. on the main divide. Oil is found in the district, probably oozing from the Te Arai (Lower Miocene) and Cretaceous strata. As usual in these bulletins, the authors pay full attention to the origin of surface-features, and one of their pleasing landscapes shows us, incidentally, the gathering of thousands of sheep under the raised rock-platform of Waihau Beach.

New Zealand now extends its responsibilities to Pacific isles; and J. Allan Thomson describes (*N.Z. Journal of Science and Technology*, vol. iv., p. 49, 1921) the geology of Western Samoa. The lava-tunnels appear to have been used as dwellings, and terraces for sleeping-accommodation have been built up in them—a feature that will pleasantly remind playgoers of the opening scene of Kelly's "Bird of Paradise."

Among American publications, we may note, for comparison with the Triassic beds of Cheshire, the cemented sand-dunes of Eocene age in north-eastern Montana (A. J. Collier, U.S. Geol. Surv., Prof. Paper 120–B, plate iv.), and the cross-bedded De Chelly sandstones (Permian?) of Arizona (H. E. Gregory, *ibid.*, Prof. Paper 93, p. 31, etc.). The latter paper, which is on the "Geology of the Navajo Country," contains notable illustrations of erosion in an arid land. E. G. Fenton (Sci. Proc. Royal Dublin Soc., vol. xvi., No. 19, 1921, 4*s.* 6*d.*), in his "Studies in the Physiography and Glacial Geology of Southern Patagonia," brings us to an unusual field. He has specially examined, through years of residence, the results of glacial outwash and of river-erosion between the Andes and the Atlantic coast. He interestingly attributes the hollows known as *bajos* to the action of water falling over an ice-front during a pause in the general retreat of the pampas glaciers. Though he traces several epochs of retreat and of renewed glaciation, during some of which lavas flowed down into valleys cut by rivers streaming from the ice, Dr. Fenton finds no evidence of any genial interglacial epoch in Patagonia.

G. A. J. C.

Artificial Farmyard Manure.

AN article in the current issue (August) of the *Journal of the Ministry of Agriculture* under the above title somewhat modestly announces what must be regarded as one of the most notable advances in agricultural science made by our oldest agricultural research laboratory, the Rothamsted Experimental Station. For many years the composition and fertilising value of farmyard manure have occupied the attention of investigators. The chemical problems involved at first sight appear simple. When cattle are fed with food rich in nitrogen there is a corresponding enrichment of their excrement. "Cake-fed" dung has long been given a high value by the farmer, and on a purely chemical basis its merit was recognised by the man of science. Hence such publications as "Hall and Voelcker's Tables," which give the "residual" values of various foodstuffs—that is to say, the value of the fertilising constituents (mainly nitrogen) in various substances present in the dung of animals to which they have been fed. But the perplexing fact emerged that dung with this higher theoretic value did not give crop increases corresponding to its assumed chemical content. Nevertheless, so strong has been the effect of the publication of these theoretic values that they are given quasi-statutory effect. Entering tenants have generally to pay compensation "for improvements" based upon the quantity and quality of the foods consumed on the farm during the years preceding their entry.

In the paper alluded to Messrs. Hutchinson and Richards indicate the solution of the conundrum. Put shortly, they have established that the whole of nitrogen in the urine of animals will not be present in the manure as applied to the crops unless a certain ratio subsists between the nitrogen voided by the animals and the carbonaceous matter of the litter by which the urine is absorbed. It seems to follow that "compensation for improvements" should not be awarded on the basis of the food supplied to the stock until the valuer is assured that the feeding was accompanied by an adequate supply of litter, the adequacy being determined by the amount of nitrogen voided by the animals.

Messrs. Hutchinson and Richards show that the factors involved are, in the main, biological, not chemical. The "making" of farmyard manure is essentially the rotting or fermentation of straw. The former writer has published a paper (*Journal of Agricultural Science*, 1919, p. 143) which establishes that straw is fermented by a new aerobic organism, *Spirochaeta cytophaga*, and that this organism requires (in addition to air) a supply of nitrogen, preferably in the form of an ammonia compound (such as, in effect, urea is). It is shown that the amount of nitrogen required for the fermentation of 100 lb. of straw is 0·72 lb. Further, if the nitrogen is in excess of this amount, it tends to pass into the atmosphere as ammonia, with the result that, with a free supply of air, the end product is dung containing about 2 per cent. of nitrogen, *whatever* the original content of the excrement may have been. Under the conditions, however, which obtain in the ordinary farmyard, where some portions of the heap may receive more excrementitious matter than others, the ammonia set free where the nitrogen : cellulose proportion is greater than 0·72 : 100 may be picked up by those portions where the ratio is less, and used to build up their nitrogen content until the whole heap reaches the characteristic and uniform 2 per cent. content of nitrogen.

Using these results, it has been found possible to make an artificial product, closely resembling farmyard manure in appearance as well as in properties, by

the addition of predetermined amounts of ammonia salts (such as ammonium sulphate) to straw. The commercial value of this development may be considerable. With the advent of the motor the supply of town dung has fallen off. Many market-gardeners are, consequently, in straits, for the so-called artificial manures are lacking in organic matter (humus), without which many garden and glasshouse crops cannot be grown satisfactorily. It may be that the ordinary farmer, too, will find a use for the artificial product. It is difficult under modern conditions to maintain sufficient animals to make all the straw produced into dung. Again, where animal excrements exist in abundance (as in milk production), lack of knowledge of the principles of the interaction between urine and straw leads to much waste of valuable fertilising material.

Another direction in which these discoveries may have a practical outcome is in removing the soluble compounds of nitrogen present in sewage. Under the existing sludge processes very little of this soluble matter is recovered. It has been shown that if liquid sewage is used to ferment straw, the effluent is practically free from nitrogen; it has all been retained by the straw.

Enough has, perhaps, been said to indicate the great practical importance of the discovery made by the Rothamsted workers. The scientific advance is not less notable, and marks another stage in the capture by the biologists of the agricultural field of research.

West Indian Zoology.[1]

By Prof. J. Stanley Gardiner, F.R.S.

In 1895 the State University of Iowa, acting through Prof. C. C. Nutting, who was already well known as a member of several marine expeditions, organised a zoological exploration of the Bahamas. Its object was twofold: to give their people experience of marine life in tropical seas, and to secure material for morphological and systematic research and for ordinary laboratory purposes. So satisfactory were the results that Prof. Nutting's staff themselves suggested a further expedition, this time to the Lesser Antilles. Preparations were commenced in 1916, so little was the entry of the United States into the war anticipated. Prof. Nutting himself went down to prospect in 1917, and finally the expedition sailed in April, 1918, the party consisting of nineteen persons, including six ladies.

Barbados was first visited, the party camping for six weeks in the quarantine station on Pelican Island, which was placed at its disposal by the Barbados Government. Groups were formed for shore collecting, row-boat work, launch dredging to 200 fathoms, land work, and laboratory observations.

Barbados Island itself is the most eastern of the Antilles, and, although now consisting largely of elevated coral and limestone rocks, contains the remains of land connecting it in early Tertiary times to South America. It was then sunk to great depths and overlaid by beds of ooze, "Barbados earth," noted for their richness in radiolaria and foraminifera. The uplift raised the sea bottom high enough for corals to thrive, and subsequent elevations are responsible for the terraced effects so apparent in the topography of the present land. The island is about 21 by 14 miles, and has now a population of nearly 200,000. All is cultivated, and land collecting was hence little likely to yield results of much value. The expedition, indeed, mainly concentrated on marine work, and the more striking animals of different groups are described; the whole forms a guide which will be of value to future workers. The general variety of life is interesting, but the uniformity of all tropical marine life in the coral-reef regions of the world is still more striking; indeed, Prof. Nutting's descriptions would apply almost equally well to faunas from similar grounds off Ceylon, Seychelles, or Fiji.

The second camping place was in the British dockyard in English Harbour, Antigua. Here, on account of the heavy swell, work had to be concentrated in the harbour and in the neighbouring Falmouth and Willoughby Bays. There were compensations in a neighbouring mangrove swamp with its peculiar fauna, in fairly smooth bottom, and in the land being little altered and still largely wild, covered with close tropical jungle. There are volcanic rocks of some age on this side, limestone rocks occurring principally in the north of the island, off which are the chief living coral reefs. The marine crustacean, holothurian, and worm faunas proved particularly interesting, and there are many observations on the modes of life of different forms. Clearly, while the whole surroundings were not so exciting to the party as those of the coral reefs of Barbados, the expedition must have obtained a large number of animals of great interest. Geographically, the mollusca in the clearly capable hands of Mr. Henderson, and the fossil geology in those of Prof. Thomas, may be expected to yield valuable information.

The immediate scientific results of this expedition are not likely to be great, but the whole idea underlying it, and its scope, are of great interest, for it might well be copied by British universities. Here was a party of nineteen charming people, half of whom were interested professionally, while the rest were students. They went off for a term, and came back to their university with a glimpse of what tropical life really is, an abiding picture which will make those who teach interesting to their students, for they will be describing what they have seen, living forms in their natural environments.

Thomas Wharton Jones, F.R.S.

Sir Rickman Godlee's memoir of Wharton Jones, reprinted from the *British Journal of Ophthalmology*, March and April, 1921 (London: Geo. Pulman and Sons, Ltd.), is a most admirable short study. It gives us in close compass not only the man's work, but also the man, from 1808 to 1891—a long life in the service of physiology and ophthalmology. Wharton Jones's work on the capillary circulation and on the processes of inflammation is memorable, and was recognised and honoured by all men of science: but the advance of the medical sciences carried the younger men far ahead of him. From Edinburgh, where Wharton Jones was one of Knox's assistants, and suffered a share of the public hatred which flared up over the Burke and Hare murders, he came to London in 1838

as lecturer on anatomy and physiology at Charing Cross Hospital; among his pupils were Huxley and Fayrer. In 1840 he was elected to the Royal Society. From 1851 to 1881 he was professor of ophthalmic medicine and surgery at University College. His thirty years of teaching and writing failed to shield him in later life from miserable poverty; he fell out of the running. He was found at last, in the bitter winter of 1880–81, "crouched over a fireless grate, his shoulders hunched up under a mass of shawls and shabby wraps, the picture of destitution . . . not only very ill, but penniless and starving." Friends saved him, and collected money for him; Huxley and Fayrer obtained from Mr. Gladstone a Civil List pension for him; Jenner obtained a Tancred pension for him. The work was ended in London, and for the last ten years he lived in a couple of tiny rooms in a cottage in Ventnor.

And here is the immense value of this memoir: that we are able to see why Wharton Jones made a better job of science than he made of life. His intense individualism, his combativeness, his opposition to the Darwinian new learning, his perverse liking for small personal grievances, his oddities of dress—these hindrances, none of them insuperable, yet were combined to keep him back from anything like the full happiness of success. "He seems to have missed," says Sir Rickman Godlee, "by so little, much that might have made him happy and successful. But this little made all the difference. . . . When all is said, it is impossible to believe that, on the whole, he had more than a very moderate share of happiness, or even of contentment."

Perhaps, as there are martyrs of science, so there are profiteers of science, men who inflate the value of scientific discoveries or seek to "corner" scientific facts. Wharton Jones was neither martyr nor profiteer. Only he could not get clear away from self-preoccupation; and it is a rather unhappy and perplexed face that looks out at us from the frontispiece of this masterly study of him.

University and Educational Intelligence.

CAMBRIDGE.—Baron R. von Hügel has resigned the curatorship of the Museum of Archæology and Ethnology, and Dr. A. C. Haddon, Christ's College, has been appointed deputy curator. Mr. R. W. Stanners, Gonville and Caius College, has been appointed University lecturer in historical and economic geography. Mr. T. G. Bedford, Sidney Sussex College, and Dr. J. A. Crowther, St. John's College, have been reappointed demonstrators in experimental physics.

Mr. F. J. W. Roughton, Trinity College, has been elected to the Michael Foster research studentship in physiology, and Mr. J. H. Richardson, Emmanuel College, Wrenbury scholar in political economy. Dr. R. L. M. Wallis, Downing College, has been awarded the Raymond Horton-Smith prize in medicine.

Mr. T. F. T. Plucknett, Emmanuel College, has been elected Choate memorial fellow at Harvard College.

Mr. H. H. Thomas, curator of the Herbarium, has been re-elected fellow of Downing College.

Two University lecturers in biochemistry are to be appointed shortly.

PROF. H. LEBESQUE, of the Faculty of Sciences, University of Paris, has been elected professor of mathematics at the Collège de France.

MR. H. P. PHILPOT, assistant professor at University College, has been appointed to the professorship of civil and mechanical engineering at the Finsbury Technical College; and Mr. A. J. Hale, chief assistant in the department of applied chemistry, to the professorship in that department. The entrance examination of the college will be held on Tuesday, September 20

LOUGHBOROUGH COLLEGE, Leicestershire, has issued a calendar for the academic year 1921–22, in which full accounts of the intellectual and social activities of the college will be found. Work is distributed over a number of faculties, of which the most prominent appear to be those concerned with engineering and pure and applied science. Full details of the courses followed are given, together with a number of full-page reproductions of photographs of the workshops and laboratories. The engineering departments were opened in 1918, and they are designed to give specialised training to boys above sixteen years of age. The course covers five years, during which time the student passes through every department found in an engineering works. On the social side there are, among other societies, engineering, wireless, and chemical and metallurgical societies, while in June last the council of the Junior Institution of Engineers sanctioned the formation of a sub-section, with headquarters at the college. These societies are doing much to bring the student into contact with industrial methods, and should serve as the much-desired link between the technical school and the works.

THE "Handbook of Lectures and Classes for Teachers for the Session 1921–22," which has been issued by the London County Council, contains a number of features likely to interest readers of NATURE. The teaching of mathematics in elementary and continuation schools forms the subjects of courses in the section on mathematics; geography in secondary schools and as a pivotal subject in education are the themes of two courses in the section on geography. Natural science is well represented by a number of courses and lectures: Prof. A. Wolf is giving five lectures on "Pioneers of Science"; Sir William H. Bragg, six lectures on crystal structure; Prof. C. Spearman and the Rev. F. Aveling, ten lectures on the mentality of individual children; Dr. W. H. R. Rivers, five lectures on the psychology of dreams; Mr. C. Burt, ten lectures on intelligence tests; Mr. P. R. Coursey, five lectures on war developments in wireless telegraphy and telephony; and Dr. C. A. Keane, ten lectures on science in elementary schools. There will also be two courses of lectures on laboratory arts. The special science lectures are as follows: "Modern Astronomical Theories," by Prof. H. H. Turner, on October 15; "The Wonders and Problems of Food," by Prof. H. E. Armstrong, on November 12; "Fallacies," by Prof. Karl Pearson, on November 26; "Geology as a Basis for Geography," by Prof. W. W. Watts, on December 10; "Yeast, what it is and what it does," by Mr. A. Chaston-Chapman, on January 21; "Aluminium and its Alloys," by Dr. W. Rosenhain, on March 16; "The Relation between Pure and Applied Chemistry," by Dr. M. O. Forster, on February 4; "The Migration of Birds," by Prof. J. A. Thomson, on February 18; and "Vitamins," by Prof. A. Harden, on March 4. All lectures are open to teachers employed within the county of London; those outside the administrative county will be admitted where accommodation permits. The Council has also arranged for the issue to teachers of science in London schools of tickets of admission to the meetings of certain scientific societies. Communications should be addressed to the Education Officer, New County Hall, S.E.1.

Calendar of Scientific Pioneers.

August 25, 1814. Sir Benjamin Thompson, Count von Rumford, died.—The founder of the Royal Institution and of the Rumford medals of the Royal Society and the American Academy of Sciences, Rumford devoted much time to science and its application to practical purposes, and was one of the first to show that heat was "a mode of motion."

August 25, 1822. Sir William Herschel died.—Pre-eminent among the astronomers of his day, Herschel extended immensely the bounds of sidereal astronomy. In 1781 at Bath he discovered Uranus. His great telescope at Slough was one of the wonders of the scientific world. He made extensive observations of the moon and planets, first established the motion of the sun in space, discovered many nebulæ, and showed that the components of double stars were moving round their common centre of gravity.

August 25, 1867. Michael Faraday died.—Unrivalled as an experimental investigator and as a lecturer, Faraday was the assistant to Davy and the successor of Brande at the Royal Institution, and in 1833 became the first Fullerian professor. Though his investigations covered a wide range, the great work of his life was his series of "Experimental Researches in Electricity," to which all later students of electricity owe a vast debt.

August 25, 1908. Antoine Henri Becquerel died.—The son and grandson of distinguished physicists, Becquerel made himself famous by his memorable discovery in 1896 of radio-activity, for which in 1903, with the Curies, he was awarded the Nobel prize.

August 26, 1723. Anton van Leeuwenhoek died.—A pioneer worker with the microscope, Leeuwenhoek made important discoveries in support of the circulation of the blood, blood-corpuscles, spermatozoa, and other subjects, and contributed 112 papers to the Philosophical Transactions.

August 28, 1839. William Smith died.—The "father of English geology," Smith published his epoch-making geological map of England in 1815.

August 28, 1863. Eilhard Mitscherlich died.—The discoverer in 1819 of isomorphism and of dimorphism, Mitscherlich spent two years with Berzelius at Stockholm, and then in 1821 succeeded Klaproth as professor of chemistry in the University of Berlin.

August 29, 1816. Johann Hieronymus Schröter died.—For more than thirty years Schröter studied the topography of the planets. He has been called the Herschel of Germany. His observatory at Lilienthal, in which Bessel worked, was pillaged during the War of 1813.

August 29, 1868. Christian Friedrich Schönbein died.—Schönbein for many years held the chair of physics and chemistry in the University of Basle. In 1839 he discovered ozone, and in 1846 made known his invention of guncotton.

August 30, 1844. Francis Baily died.—After amassing a fortune on the Stock Exchange, Baily devoted himself to astronomy. He was a founder of the Royal Astronomical Society, reformed the Nautical Almanac, edited a star catalogue, and during the years 1838–42 repeated the Cavendish experiment for determining the density of the earth.

August 30, 1888. Johann Peter Griess died.—In 1858 Griess discovered the first diazo-compound, and three years later the first azo-colours, which have produced a revolution in the art of dyeing.

August 31, 1900. Sir John Bennet Lawes, Bart., died.—A great pioneer in the application of science to agriculture, Lawes was the founder of the Rothamsted Experimental Station, where for fifty-seven years Gilbert was his collaborator.

E. C. S.

Societies and Academies.

Paris.

Academy of Sciences, August 8.—M. Léon Guignard in the chair.—A. **Demoulin**: Surfaces generated by circles.—P. **Fatou**: The domains of existence of certain uniform functions.—M. **Potron**: The representation of the group of 27 right lines in a group of quaternary collineations.—K. **Ogura**: The movement of a particle in the field of a charged nucleus.—L. **Dunoyer**: A new spectrum of cæsium. The metal was contained in a quartz tube, with plane parallel quartz ends, and surrounded with a wire spiral in which high-frequency currents were produced. The whole could be heated uniformly in an electric furnace. The vapour commenced to be luminous at 100° C., reaching a maximum luminosity at 250° C. The spectrum consists of fine lines with no trace of a continuous background. Measurements of more than 300 wave-lengths for the low-temperature spectrum are given.—S. **Procopiu**: Magnetic double refraction of mixed liquids and crystalline structure.—E. **Moles** and F. **Gonsalez**: A new revision of the density of oxygen gas. Special attention has been paid to varying the method of preparing the gas, and density measurements are given for oxygen prepared from potassium permanganate, potassium chlorate, mercuric oxide, and silver oxide, and by the electrolysis of water. The general mean is 1·42889, differing only by one part in 10,000 from the figure at present accepted, 1·42905. The densities, classified according to the method of preparation, showed no sign of any systematic error.—A. **Mailhe**: The preparation of a petrol from a fatty oil. Linseed oil was passed over a catalyst composed of copper, magnesia, and kaolin heated to 550°–650° C. The volatile product was further treated with hydrogen and reduced nickel at 180° C. After refining, petrol and kerosene fractions were obtained. The petrol contained benzene and naphthene derivatives.—G. **Vavon**: The velocity of the reaction in the hydrogenation by platinum black. The rapidity with which the hydrogenated body formed leaves the surface of the catalyst is a governing factor in the velocity of the reaction.—V. **Yéramian**: The synthesis and dehydration of ethylpropylphenylcarbinol. Ethylpropylphenylcarbinol was prepared by the Grignard reaction from propylphenylketone and ethylmagnesium bromide. This can be distilled without decomposition under low pressure (25 mm.), but is readily dehydrated, producing an unsaturated hydrocarbon, $C_{12}H_{16}$, probably 3-phenyl-3-hexene.—V. **Lubimenko**: The state of chlorophyll in the plasts. A study of the causes of the inactivity, from the point of view of photosynthetical reactions, of pure chlorophyll prepared by chemical methods. It was found that treatment of the living tissue by various solvents, besides coagulating the proteid substances in the plasts, produces sensible changes in the optical properties of the green pigment. The chlorophyll of the leaves of *Aspidistra elatior* can be completely removed by extraction with water. The absorption spectrum of the material thus extracted is absolutely identical with that of the living leaf. The chlorophyll is intimately related to the proteid substances of the plasts, and this is probably of a chemical nature.—M. **Romieu**: The crystalline inclusions of the eleocytes of Nereis and their relations with the eosinophil granulation.—C. **Levaditi**: Embryonic leaflets in relation to pathogenic micro-organisms. Mesodermic infections are caused by bacteria, fungi, spirillæ, and protozoa, whilst infections of the ectoderm are produced by virus, usually invisible and capable of passing filters.

SYDNEY.

Royal Society of New South Wales, July 6.—Mr. E. C. Andrews, president, in the chair.—W. R. **Browne**: Note on the relation of streams to geological structure, with special reference to "boathook bends." The influence of geological structures on the courses of streams, as illustrated by certain rivers of New South Wales, is discussed, and it is suggested that what Dr. Griffith Taylor has termed "boathook bends" in rivers are in many cases to be attributed to the presence of directive geological structures rather than to river-piracy and the breaching of divides.—Marie **Bentivoglio**: Notes on cassiterite crystals from New England district, New South Wales, and Stanthorpe, Queensland. The crystals were taken directly from hand-specimens of igneous rocks obtained from Stannum, Pheasant Creek, Mandoie Station, and Stanthorpe. Crystal habit varies with locality. Almost all the crystals are twinned, the twinning occurring on the *e*(101) face, according to the usual law. Doublets are the commonest grouping, but triplets and quartuplets were also observed.—Dr. E. E. **Turner** and F. H. H. **Wilson**: The decomposition of dimethyl oxalate by acetic acid. Pure methyl acetate may be prepared by the action of 80 per cent. acetic acid on dimethyl oxalate, the theoretical quantities of reactants being used. The yields obtained are virtually theoretical.—Dr. L. A. **Cotton**: The Kurrajong earthquake of August 15, 1919. The special feature of the Kurrajong earthquake is the peculiar **Y**-shaped character of the isoseismals. One arm of the **Y** and its stem lie subparallel to, and superimposed over, the line of structural weakness shown by the Kurrajong fault and the Glenbrook monocline. The other arm of the **Y** is not known definitely to coincide with a fault zone. The direction corresponds to a major direction of tectonic weakness—the Permo-Carboniferous geosyncline—and also to numerous large faults in the Maitland district. It is suggested that the earthquake was caused by block faulting in which the south-eastern corner of a crustal block has foundered. This would account for the peculiar form of the isoseismals. The shape of the boundary of the sound area confirms the **Y**-shaped form of the isoseismals.
